

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

### PART I.

#### HEATHEN.

PAINTING and sculpture seem the natural offspring of the human mind : they are coeval with music and song. They are to be found—rude indeed, and uncouth—amongst the most savage of the human tribes : wherever civilization has penetrated, the rudiments of the fine arts have been found long established ; some Laban of the desert had his household gods carved in wood, and enriched with colours and with precious stones. Representations of historical events, or personifications of abstract ideas of good and evil, are common to all communities, civilized or savage ; nor is it less remarkable than true, that the fine arts of almost all ancient nations have been closely united with devotion. Religion gave a moral expression and a heavenward look to all that sprang from human genius : the first hymns were in honour of the immortals ; the earliest specimens of art represented the gods whom men worshipped. When civilization and knowledge brought reflection and philosophy, men began to disregard the sculptured stone and the painted symbol, and look higher, and think more deeply. The idols, before whom the early nations of the earth were taught to bow, were only abandoned because knowledge purified our sight and mind, and bade us bow to the invisible Power, of which the best had only dreamed rather than believed.

Yet there is no doubt that the fine arts—or, in other words, the gods of wood and stone—aided in raising man out of his barbarous condition. Art was the language in which, after the confusion of tongues, men spoke and comprehended one another. The first rude figure was succeeded by one more skilfully made : elegance began to dawn amid deformity, and men grew polished

with their productions. Nor was this all. Art walked abroad, like one of the early missionaries, and speaking to the barbarous tribes of Asia and Europe through painted groupes and sculptured figures, historical and religious, spread abroad a sense of something lofty and spiritual. Increasing taste required art to become more graceful and beautiful : science was applied ; true proportion was discovered ; and the marbles of the men of Attica assumed the shape and aspect of gods. It was so in Egypt, in India, in Greece, and in Italy : religion breathed sublimity into song, and an air of heaven over sculpture and painting. A divine nature triumphed over that of earth in the Apollo, modest beauty kept down voluptuousness in the Venus, and that terrible majesty was diffused over the Jupiter which makes us think of thunder as we look on him.

It was so with the heathen, nor was it much otherwise with the Christian. A religion which, addressing the mind and soul, excluded the more visible and sensual, refrained not from accepting the aid of the fine arts, which, in the train of the false deities, aided in civilizing much of the earth. Our Saviour came to save the world—to raise men from their knees, humbling themselves to their own handywork, and bid them look to heaven, and think of immortality. The Dianas, Junos, Apollos, Minervas, and Jupiters, hitherto adored, were now to be as nothing, or as beautiful productions only in marble and brass ; and Faith, and Hope, and Charity were to take their places, and establish themselves without temples or altars. The oracles were struck dumb : incense no longer ascended to the gods of Olympus, and the intellectual eye, touched by a new light, was directed towards that great and invisible One of whose existence the heathen had but glimmerings.

Much, however, of the world which is in light

now, lay then in darkness : the blue-eyed savages of Germany, and the painted barbarians of Britain, knew neither the language nor the arts of civilized life. To them the words of the new religion were an unknown tongue ; and the fine arts, which had seasonably helped the heathen, did the same good office for Christian preachers, and interpreted an intellectual and spiritual doctrine to the comprehension of our barbarous ancestors. Those hordes knew neither Latin nor Greek, but the fine arts speak all languages ; and a sculptured cross, the virgin and child, the annunciation, the raising of the dead, the ascension, and other sculptures and pictures, made out the meaning till a knowledge of the language enabled the preachers to add eloquence to art. Nor was this laid aside when man became civilized, and knowledge was widely diffused. Christian divines had still to combat with heathen hankerings : the nations of the earth clung obstinately to their false gods : they thought of the pleasures of a sensual religion ; of the midnight processions and moonlight mysteries ; of their numberless deities : nor can it be said truly that ancient superstition was subdued till the prudent church of Rome placed saints, male and female, in the niches of the heathen Apollos and Dianas, and compensated for the mystical carnivals by thanksgivings and carnivals.

The fine arts in the service of the church of Rome resumed much of their original glory. Sculptors and painters, animated by a religion which bestowed honours on earth and opened the doors of heaven, wrought in the spirit of a new inspiration, and their works are still considered little less than miracles. They blushed at the nude simplicity of the heathen times, and desiring to work in the spirit of religion, infused more holiness into their compositions ; while, in compliance with the decent necessities of a cold climate, they were profuse in robes and draperies. At this period, learning was confined to few ; a knowledge of the Scripture was chiefly limited to the priesthood : and the rest of mankind were in almost total darkness. By the husbandman, the mechanic, and the shepherd, the labours of the sculptor and painter were received with gratitude, and regarded with awe and wonder. Of religion they knew no more than the priest taught and the artist darkly intimated ; and it is recorded of them that they all but regarded the splendid creations of art with a reverence allied to superstition. They were not to remain in darkness long. Printing came like a sunburst, with knowledge in her train, opening the Scriptures to all nations. Men read and interpreted for themselves : and considering art as a

thing lovely in itself, but rejecting it as an untrue or ambiguous interpreter of God's word, they cast it like a demon out of religion, commanding it henceforth to meddle only with material things.

In these introductory remarks, two leading epochs of the fine arts are indicated, viz. 1. Their condition among savage or imperfectly civilized nations, when they represented the gods whom men worshipped, or the heroes whom they produced ; and their character among the polite and polished Heathen, when science and poetry elevated them into the regions of beauty and sublimity.—2. The appearance of the fine arts in Christian Europe, when a new religion impressing them with a new spirit, employed them in the interpretation of the word of God : with their character, since knowledge, dismissing them from religion, confined them, especially in Britain, to matters historical, poetical, and domestic.

The fine arts have never in any new discovered country been found in a high state of cultivation : indeed, with no nation have they ever risen into beauty or majesty till science came to the aid of invention and skill of hand. Yet in each country, whether barbarous or semi-barbarous, the rudiments of future excellence have been discovered. Egypt had its dawn in art, as well as England : before the temples of Carnac or the cathedral of Canterbury arose, there were ruder structures, which formed the germs of those, as seed does of the future oak ; and we have evidence that in both lands a coarse sort of sculpture prevailed, commemorative of the deeds of warriors, or the appearances of the gods. The rocks of Britain, of India, and of Egypt, still bear the rough impressions which unenlightened chisels traced in attempting to delineate the human form, while the temples of the three lands contain many elaborate works to which science has contributed proportion, and talent beauty. In all these early efforts we have energy of muscle, but no dignity of character ; strong action, but no propriety—and they resemble each other in a matter equally important to our inquiry : colour was brought to help out the imperfect labours of the chisel, and to communicate to low relief something of the look of painting.

In writing the history of art for those remote days we are telling its story in more modern times. When the new world was discovered, temples, and statues, and paintings, and other indications of civilisation were found. Spanish writers claim for those works merit of a high order : but the adventurers who overran Mexico and Peru seemed willing to look on all things with wonder, and it was alike their object to

exaggerate the looks of the land, and the labours of the people. The statues and pictures, on which Spanish writers lavish so many words of admiration, were, in truth, but uninspired masses and brilliant daubings; remarkable chiefly for the variety of their colours, and for the bushels of pearls scattered about them in bracelets, and anklets, and bands. Robertson was one of the first to observe that such descriptions contained more of romance than of truth, and an examination of some of those Mexican marvels more than confirmed his suspicions.

Yet it cannot be denied that the fine arts among those gentle savages had risen higher in science and poetry than with any other barbarous people. Their ornamental works, imitated from herbs, and shells, and flowers, were indeed beautiful, and traced with a neat hand and an accurate eye. Without being scientifically correct they have all that the eye desires, and that has always been found sufficient. Nor should their singular pictures, wrought with various coloured feathers, a more ingenious sort of tapestry, be forgotten. In wood carving they likewise excelled; nay, some of the tatooings of the South-Sea Islanders and North-American savages exhibit much skill and even taste. The inhabitants of New Holland seem to come as close to the brute, as lord Monboddo could have desired; they neither build huts, carve war clubs, nor fashion gods; yet they now and then paint themselves with care, and when an unexpected feast offers itself, they break into voluntary song.

The sun of scientific art rose first on Egypt, or on India. History leans to the former, tradition to the latter; but both have the highest claims to antiquity of all the nations of the earth. Looking on the works of both, no one can with certainty say that the excavated tombs and palaces of Upper Egypt are more ancient than those of Elephanta or Elora, in Hindostan. The character of the fine arts in each land seems to be the same, though unquestionably the African artists wrought with more scientific skill, though not with higher imagination, than the artists of Asia. In both countries their object appears to have been the same; and in both, architecture, sculpture, and painting, were united. In this they closely resemble, and in this alone, our Gothic cathedrals, where architecture and sculpture blend and unite in one grand harmony, and,—

"Each gives to each a double charm,  
Like pearls upon an Ethiop's arm."

The ancient temples, of which we speak, with all the sculptures they contain, seem to have been

conceived at once: there the sister arts cannot be separated, without the destruction of both. They were in their character religious or monumental. Their object was to awe and astonish, and that they succeeded we have the attestations of the wisest and most intelligent of mankind.

The earliest of the Egyptian and Indian temples intimate that they were formed before the principles of architecture were fully understood. The art of uniting millions of small stones into one elegant and harmonious structure, seems to have been in those days unknown; and it was perhaps quite as easy to imagine a pyramid or a temple, as to discover cements and metals for uniting the stones, and the means of elevating them a hundred feet in the air. To cut a temple or a tomb out of a solid hill or mountain was one way to avoid the difficulty of uniting many things in one: it was a bold idea, and to moderns acquainted with the facilities of masonry, seems equally laborious and difficult. But they had no scaffolds to raise, no cements to invent, and no powers to create capable of raising columns sixty feet high, without joint, into the air; or, more ponderous still, those crowning blocks, which lie horizontally over the columns, and form whole ceilings of halls, as are still to be seen in the architecture of the Egyptians. The architects of those magnificent excavations probably smiled when a reformer in art first proposed to saw a rock into a multitude of small pieces; shape these into cornices, capitals, and architraves; and then, with mortar, metal, and pulleys, proceed to unite them into one lofty and splendid edifice.

All that the excavating architects required was a correct model, and sharp cutting chisels. The beauty of their work was chiefly internal. A hill with its trees budding, streams running, and flocks grazing, was a palace within, on which were lavished all the taste and invention of man. The palaces imagined by the poets for the fairies and their queen, scarcely surpass the realities on the banks of the Nile, or the hills of Hindostan. The most spacious of nature's caverns, with all their crystallizations, cannot be compared with the stupendous and regular excavations of the hand of man. There are temples extending some hundreds of feet into the solid rock of the mountain, formed with centre and side aisles, supported by wreathed columns or colossal figures of fifty and sixty feet high, carved with great skill, and still exhibiting traces of dazzling colours and gildings, which, in torch light, must have looked truly brilliant. Nor is this the sole wonder; sculptures representing the gods of the land, the kings of the country, or the

actions of warriors, were carved in all the recesses or spaces in the wall. Nay, the columns themselves were sometimes covered with low reliefs. The figures of the divinities reached often to sixty feet in height, their eyes were enamelled, their robes painted or gilt, their limbs ornamented with armlets and anklets, and a certain severity of expression was meant to denote the dignity of gods.

But hills were not always at hand, nor rocks commodiously enough situated for the purposes of architecture, and the convenience of princes; and man had to exercise his invention in order to bring the palace and temple, with all their statues, to the side of the sea, or the bank of some navigable river, where commerce had begun to spread her sails. It was then that architecture made her second grand movement; she ceased to bore her way into the obstinate mountain, but turning the rock into a quarry, found materials which enabled her to add external beauty to internal accommodation; and rear those temples which still triumph over the folly of conquerors and the influence of time. This invention had other merits; in cutting a temple out of a hill the artist had to take the materials as nature chose to send them; they were often coarse, always unequal, and occasionally ill fitted for delicate carvings or polished workmanship; painting and gilding were applied as remedies, but these were not always effectual. The new invention included choice of materials; to the freestone of one hill was added the veined and variegated marble of another, and with both was united the dazzling and enduring porphyry; a substance difficult to carve. How the vast masses which compose those buildings were raised to their places is still a matter of surprise and speculation; but how the solid porphyry was cut and polished is more surprising still; it is too hard for ordinary steel, yet it seems to have been wrought with ease by the masons of Egypt.

These temples were the admiration of the Greeks, as well as of the Romans. Nor were they few in number: Britain has but one St Paul's; but the banks of the Nile had hundreds of such structures. The character of the excavated works was visible in these new erections; the columns seem capable of sustaining a hill, the figures fit to support a mountain; nothing is light or graceful, all is heavy, broad, and massive; the architects seemed still to feel that they were working in the bowels of the rock, and had to leave pillars and supports equal to hold up mount Pelion. Their solidity and strength was much increased by the absence of the arch; in all masonry a rent or a settle is sure to

take place where an arch is, if the foundation be infirm, for a perpetual push is kept up against the abutments: in Egyptian architecture, all is horizontal; there were neither slopes nor circles, nothing but downright weight. The temples of Hindostan are almost the same in every thing; both seem to have originated in one mind. "To me it appears," says Erskine, writing of Elephanta, "that while the whole conception and plan of the temple is extremely grand and magnificent, and while the outline and disposition of the separate figures indicate great talent and ingenuity; the execution and finish of the figures in general—though some of them prove the sculptor to have had great merit—fall below the original idea. The figures have something of rudeness and want of finish, the proportions are sometimes lost, the attitudes forced, and every thing indicates the infancy of the arts—though a vigorous infancy."

These words apply to much of the early sculpture of Egypt, as well as to that of Hindostan; there is something grotesque about both; yet it seems never to have occurred to those who criticised the latter, that a different scale of proportion in the manufacture of deities is a sacred rule of the land. This accounts for the exaggerated shapes and inharmonious proportions visible in the statues of Siva, Boodh and others. "The Egyptian statues," observes Flaxman, "stand equally poised on both legs, having one foot advanced, the arms either hanging straight down on each side, or if one is raised, it is at a right angle across the body. Some of the statues sit on seats, some on the ground, and some are kneeling, but the position of the hands seldom varies from the above description; their attitudes are of course simple, rectilinear, and without lateral movement; their faces are rather flat, the brows, eyelids, and mouths, formed of simple curves, slightly, but sharply, marked, and with but little expression; the general proportions are sometimes more than seven heads high; the form of the body and limbs rather round and effeminate, with only the most evident projections and hollows. Their tunics, or rather draperies, are in many instances without folds. Winkleman has remarked that the Egyptians executed quadrupeds better than human beings."

The artists of Africa were more learned, if not more poetic, than their brethren of India. They included astronomy, as well as religion and history, in their works. Whatever they made had a meaning, clear to them, though dark to us, yet not more so than much of our own sculpture will prove to foreign nations in a future age, when they sit in judgment upon

sandals and half boots, buttoned coats and Roman togas. What the two colossal elephants had to perform which still stand nigh the entrance of the temple of Elora, no one has conjectured; nor has the meaning of the stupendous Sphinx, still a wonder in a land of wonders, been clearly accounted for. The former are cut out of detached portions of rock, and seem to have been intended as guardians to the sacred temple; the latter has recently been bared as low as the belly, and instead of being composed of quarried blocks, it is now found to be produced from a huge earth-fast stone, or cut out of the salient angle of an immense rock. The head and body are of one piece, and connected with the soil; the legs and paws are of the like material, and though some have doubted whether the seams or veins which cross them are not joints, they are much more likely of a piece with the body. The breasts, shoulders, neck, and face are those of a human being of the Nubian character; the expression is placid. "No people, either ancient or modern," says Champollion, "ever conceived the art of architecture in so sublime and grand a scale as the ancient Egyptians. Their conceptions were those of men a hundred feet high; and the imagination which in Europe rises far above our porticos, sinks abashed at the foot of the hundred and forty columns of the hypostyle of Carnac." He might have added, that the largest statues of modern times are but like figures carved from a cherry stone, compared to the gigantic gods and heroes of the land of Egypt.

Both Greeks and Romans seem to have examined the works of art, on the banks of the Nile, with an eye curious, if not tasteful. Some of their measurements have proved erroneous; nor has the opinion pronounced on the excellence of the sculpture been supported by specimens such as have descended to us from the artists of Greece. The splendid varieties of the marble and the porphyry, together with the bright polishing and brilliant colours, united to dazzle men's eyes and influence their judgment; they found temples more massive, and statues more lofty, than they looked for, and they pronounced accordingly. The same may be said with regard to later accounts: the French and the British have united to explore and explain the perishing wonders of the banks of the Nile; but it may be remarked, that no artists of approved taste and genius were in the train of those explorers, and that we have reason to believe that the gigantic dimensions, the lustre of the materials, and the careful polish of the workmanship, were to the visitors grace, expression, and sublimity. In-

deed, in the eyes of many, whatever is large is great; a statue twelve feet high has twice the grandeur of one of six, while one of twenty-four has but half the sublimity of one of forty-eight. Two of the noblest statues, however, of these our later days, are but eighteen inches high—the Michael Angelo and the Raphael of Flaxman.

Yet the architecture of Egypt may claim the name of sublime, if the title be not too noble for works produced by mechanical skill. Temples, which seem to be as stable as the mountains, are still standing to justify men's admiration; while colonnades of solid stone, sixty feet high, obelisks higher still, without joint, and walls composed of enormous blocks, everywhere abound; fractured or overthrown by some convulsion of nature, rather than by the hand of time. The sculpture of the land is not at all equal to the architecture. Statues, indeed, of fifty and sixty feet high abound, and walls and pillars are carved over with figures, singly or in groups; but the former are not very graceful, either in proportion or in expression, and the latter are chiefly rude etchings or sinkings, in which durability has been the main object. A figure, sixty feet high, cut out of solid porphyry, standing now as it did three thousand years ago, amid the arid deserts of Upper Egypt; or the god Sisaal, of twice the height, hewn out of rock, discovered by Burnes among the snowy mountains of Koosh, are sublime from their antiquity more than from their dimensions, or the character impressed upon them. These works may be called magnificent, but they cannot, with any propriety, be called beautiful, in the natural sense of the word. The Nubian features can never be reconciled to our notions of the graceful in form; nor have they been redeemed from the grotesque by sentiment and feeling: the lumpy lips, the wide cheek bones, the "forehead villanous low," with perpendicular draperies descending like icicles or petrifications, could never, though painted with the brightest colours, or gilt from head to heel, rank for a moment with the poetic creations of the dullest days of Greece.

By the curious inquirer the contrast between the master and the scholar, between Egypt and Greece, may be traced, even in the works which have descended to our own day, and are now in this country. This was visible in the earliest times; and the same paternity was boldly claimed then, as well as now, for the statues of Thebes and Athens. But this applies rather to the mode of handling than to the ruling beauty of the sculpture character and sentiment. The early statuary of Greece had rigid limbs, inflexi-

ble muscles, hard shut lips, and stony eyes, like the statues of Egypt, but here the resemblance ceases. In the rudest sculptures of the former the dawn of poetic beauty is visible; in the most savage forms there resides a certain majesty of manner, in which the works of the latter have no share. Had critics and historians asserted that Greece imitated Egypt in employing art to tell the story of her history and her religion, they would have been nearer the truth perhaps. Let us examine more closely into this matter.

When Denon beheld at the head of his savans the ruins of ancient Thebes he exclaimed, "This celebrated city, the size of which Homer has characterized by the single expression of the hundred-gated, a boasting and partial phrase, which has been repeated with much confidence for many centuries; this illustrious city, described in a few pages dictated to Herodotus by Egyptian priests, that have since been copied by every historian,—celebrated by the number of its kings, whose wisdom had raised them to the rank of gods,—by laws which have been revered without being promulgated,—by science involved in pompous and enigmatical inscriptions, the first monuments of ancient learning that are still spared by the hand of time;—this abandoned sanctuary surrounded with barbarism, and again restored to the desert, from which it had been drawn forth; enveloped in the veil of mystery and the obscurity of ages, whereby even its own colossal monuments are magnified to the imagination;—still impressed the mind with such gigantic phantoms, that the whole army suddenly, and with one accord, stood in amazement at the sight of its scattered ruins, and clapped their hands with delight, as if the end and object of their glorious toils, and the complete conquest of Egypt, were accomplished and secured by taking possession of the splendid remains of this ancient metropolis."

The account of Thebes by a later traveller, Mrs Lushington, is more to the point:—"When I compare the descriptions of Denon and Hamilton, I find them essentially correct, yet without giving me any idea of the glorious reality. No words can impart a conception of the profusion of pillars, standing, prostrate, inclining against each other, broken and whole, stones of a gigantic size propped up by pillars, and pillars again resting upon stones, which appear ready to crush the gazer under their sudden fall; yet on a second view he is convinced that nothing but an earthquake could move them: all these pillars covered with sculpture, perhaps three thousand years old, though fresh as if finished but yesterday; not of grotesque and

hideous objects, such as we are accustomed to associate with ideas of Egyptian mythology, but many of the figures of gods, warriors, and horses much larger than life, yet exhibiting surpassing grace and beauty." These colonnades, obelisks, porticos, and statues are in hundreds and thousands, filling the vast plains almost as far as the eye can reach, and extending over five modern villages. Should any city of modern times be exposed without repair to the storms and the whirlwinds of three thousand years, their noblest buildings will be as dust, and the plough will pass over them, nor be impeded in its progress.

The sculptures to which our fair traveller alludes are to be found in the temple of Luxor, a portion of Thebes. It will be observed how much in subject, though in nothing else, they are akin to the marbles of the Athenian temples. On the eastern wing of the north front of Luxor are sculptured the exploits of one of the early conquerors: the enemy are driven roughly back upon a fortified town, from whence they had issued, and the victors are pressing forward, with the design of entering the place with the vanquished. The commander is conspicuous in a war chariot drawn by two horses; a globe surmounts his helmet, with a serpent on each side; an arrow is leaving his bow, and beside him is a lion rushing forward. His horses are in full gallop; under their hoofs are scattered the dead and the dying. The enemy are in disorder and flight; men fall, pierced with wounds, from their chariots; the main body are pushed over a precipice into a rapid river; the town is in dismay; on the walls aged matrons and men run to and fro, shrieking and stretching out their hands, while some of the more resolute citizens sally out, led by a young warrior, whose robes and tiara mark him of note. Various portions or episodes of the same battle are represented on other parts of the building; everywhere the Egyptians are prevailing, and the Indians or Persians are suffering; the short, close dresses of the former contrasting well with the flowing robes of the latter. It is more than likely that these sculptures were stained or painted. That painting generally in ancient times came to the aid of sculpture, is too well established to be questioned.

It appears that the fine arts were chiefly dedicated to history and religion in the land of Egypt. What the houses were like in which the people dwelt, how the walls were adorned, and what their domestic gods resembled, we have no account. Priests sacrificing to the gods, solemn processions, battles fought, cities assaulted or stormed, kings and rulers, living or dead, cut out in stone, couching lions, and crocodiles, and

serpents, slaves of gigantic stature supporting the roofs or porticos of temples, and colossal figures, half man half beast, guarding the way to tombs or the entrances to palaces, were the subjects on which Egyptian genius employed itself. These were the work of many centuries; art seemed to have advanced little. There was much to wonder at, yet nothing was poetic or elegant. We marvel how they raised such massive and enormous piles; we measure the stones, and we calculate the weight of the gigantic statues, but it would be unsafe to commend, as matters of high genius, any of their works save their architecture. The great merit of their conceptions was durability. The people became rich, luxurious, and degenerate, and their country was invaded and conquered by every nation that chose to draw the sword and march against it, from the days of Nebuchadnezzar to those of Napoleon. But so massive and so mighty were the works of the people, that the most savage of conquerors were unable to prevail against them; they had raised tombs, and temples, and pyramids too vast and strong to be overturned by man, or even by time; and those structures still stand, among the pathless deserts, to prove that intellectual giants lived in the earth in the earlier days.

Colossal magnificence seemed the object of the Egyptian artists; that of the Greeks was simplicity, beauty, grace, and sublimity. The African sculptor desired to astonish; the European wished to delight: the former wrought by mechanical rules, and produced his figures by a formal process, in which the hand had more to do than the mind; the latter called in poetry to his aid, and all but endowed his works with motion and speech. Nor did all this difference arise from more dextrous or more delicate workmanship; it lay as much or more in the original design. The happiest labours of a Greek chisel would have been unable to redeem one of the most naturally imagined statues of the land of Egypt from the original sin of stiff and corpse-like conception. But this triumph of poetry in art was not achieved at once; nor did it arise from the exertions of one master mind. In the earliest and rudest of their statues something lofty and god-like appears, as it were, in the dawn. In truth, the Greeks were perhaps, one and all, the most imaginative of nations; they listened to the songs of their bards with a rapture which nothing as divine would excite now, and they wandered among their groves of statues of heroes and of gods, and thought of the time when some achievement of their own would entitle them to similar honours. It is true that

Greece borrowed the idea of its art from Egypt; the stiff and inflexible postures of the latter are visible even in statues which have come down to our own days. Ease and nature came with poetry to help the former, and those miracles, not of size but of sentiment, were wrought, compared to which the happiest efforts of the artists of the Nile are no better than the doings of the Egyptian magicians in the presence of Aaron and his rod.

The poetic feeling of the Greeks is expressed in all their works; all that they looked on and loved was at once endowed with spirit and with life. The neighbouring hill had its divinity, the distant mountains were peopled with gods, the woods, and the streams, and the fountains were filled with things immortal and lovely, and the heavens above and the earth beneath teemed with spiritual existence. Nor were they cloudy, and dim, and undefined, like the visions which pass before our gothic fancies. What the Greeks believed in, they imagined they saw; and whatever they saw, they had the art to endow with shape, and inform with sentiment. Even their most extravagant conceptions are redeemed by the grace and elegance of their handling; the Centaurs, half man and half horse, were all but rendered acceptable to the heart by the delicacy with which the fiction was treated. The whole land of Greece, including its isles and Asiatic provinces, was filled with temples, and statues, and paintings. Even this is still visible to travellers; a stream cannot be forded, a field ploughed, or a grave dug, without finding fragments of gods and reliques of heroes. No one need return without the foot of a Venus, the hand of an Apollo, or the head of a Pan or a Jupiter.

Nor were those statues cold and inanimated personations of popular belief; all was in character and keeping; nothing was mean or vulgar; the seal and impress of something divine was upon them. Venus was known by her loveliness, Apollo by his youthful beauty, Juno by a serene majesty, Neptune by his maritime look, Minerva by her thoughtful gravity, Bacchus by his reveling air, and Jupiter by the majestic grandeur of his brow. All was action,—graceful and elegant action; there was no straining, no picturesque attitudes; whatever was done was accomplished with ease, and without muscular effort. The action, too, in which they were put was individual and historic; Pan played on his pipe, Mercury fitted on his winged sandals, Apollo shot his arrow at the serpent, or sat harping to the celestials, Venus showed the golden apple in her hand, not unconscious of the charms which ob-

tained it, Minerva assumed her helmet and spear, and stood ready for war or wisdom, Bacchus returned reeling from India, Neptune grasped his trident, and extended his hand over the empire of the sea, while Jupiter brandished his thunderbolt, and singled out his victim. The looks and lineaments of these creations were human nature exalted and spiritualized; all that was mean, coarse, ill-shapen, and earthly was avoided; no detail was entered into; the appearance of youth was given, without anything which hinted of the nurse or the cradle; and the looks of age were bestowed, without the furrows and the decay incident to man. A divine spirit seemed to have entered into the loveliest of all created shapes; the beholder felt a lifting up as he gazed: the statues of the gods were the poetry of the land charmed into marble.

Human deeds were treated by the Greek artists in something of a similar manner. Each individual was characterized by the action in which he was represented. The forms were noble, the proportions just; age was there, and so was youth; yet any person of knowledge or taste could see at once that they were all human, not divine. The actions which the gods performed were done with a divine ease, which cost the body no exertion. The actions of man demanded muscular effort, and were accomplished with labour and difficulty. Apollo and Bacchus were celestial conquerors, yet look at their smooth and elegant forms; men with such bodies could not have prevailed in the strife as they did. It was otherwise that Hercules was represented; he is all sinew, and muscle, and bone; he was of earth, and as he wrought more with hand than mind, the sculptors delineated him of gigantic proportions, and gave him members fit for the tear and wear of his undertakings. He is shown resting on his club, and reposing from his toils like a mere mortal; while Apollo slays the Pythian serpent with the ease of a god, and seems unconscious of doing anything uncommon. Few of their statues were meditative; there was a dramatic spirit in the people, which may be seen as strong in their epic poetry, and in their works of art, as it is in their dramas. No figure stood there the idle occupier of its pedestal; a god was busied in some action for the good of Greece, or the overthrow of its enemies; while a mortal seized his sword to march to war, or his harp to charm his hearers with harmony. Life and thought were impressed on sculpture and painting.

All this was not accomplished by inspiration alone; study and science were resorted to. The greatest of all mechanical achievements is to

draw the human figure with perfect truth of proportion and outline; the greatest effort of the mind is to endow that figure with high feeling and sentiment; to unite both is a power bestowed on few. To draw a hill or a tree requires a fine eye and a true hand; but the hill may be of irregular shape, and the tree may not be equal on all sides, and a slight deviation is not observed, and affects not the character of either: it is otherwise with a true proportioned human figure; the separate parts are in themselves so beautiful, and the union of the whole so harmonious, that the slightest deviation injures the figure, and robs it of that perfect grace which it possesses more than any other created thing. In the science of their art the Greeks seem to have excelled all other nations. Nothing in sculpture in ancient Rome or modern Europe can be compared to the unity and harmony of their statues and groups; no drawing has appeared to rival the exquisite elegance of their bounding lines. All with them is easy, graceful, and simple; there is no straining for effect, no picturesque threats to arrest the spectator; they trusted all to natural beauty of form and divinity of sentiment. Their statues still survive in hundreds to attest the truth of this assertion; and though their paintings have perished, we have every reason to believe that they at least equalled the sculpture in truth and beauty.

In Egypt and India, architecture, sculpture, and painting, were united: in Greece, the inventive genius of the people soon gave an individual existence and dignity to each: or rather sculpture and painting escaped from the mechanical clutches of architecture, and rose into the regions of poetry as separate arts. It is true that a Greek temple was raised for the worship of the gods, and that on its pediments and niches, statues and groups were carved, and scenes painted, representing the persons or exploits of those divinities; here, however, the resemblance ends; the statuary and the paintings in the temples of the Nile were subordinate to the architecture; the images supported the roof or the pediments, the reliefs were flat and unobtrusive, and the painting, or rather staining, was all subdued and kept down, so that the genius of architecture triumphed. The Greeks soon perceived that architecture was of a limited nature, and that the two slaves had more of true divinity in them; the fairest proportions, the finest combinations, and the most exquisite workmanship of the former told no story contained no sentiment, and performed no action fabulous or real; the latter had sentiment, action, and, I had almost said, speech. A temple became in Greece a receptacle for exhibiting the

miracles of art. Gods were wrought in marble, in ivory, and in gold, and pilgrims and worshippers approached, rather to behold the majestic beauty of Minerva, or the stern sublimity of Jupiter, than to wonder at the structure which contained them.

Let no one, however, suppose that I am insensible to the merits of the Grecian architecture; if it failed to rise with its sister arts, it was from no want of genius in those who professed it, but rather its own character, which limits it and confines it more to the eye than to the mind. A little was taken from the durability discernible in the Egyptian works, and more was added in the matter of elegance; much that was heavy was avoided; columns were shaped by science, and with some reference to the appearance of the structure they had to support; capitals were rendered more airy and graceful, and those enormous rocky roofings were dispensed with in which the architects of the Nile excelled. Nor was this all; ingenious men divided architecture into degrees or orders; one represented simplicity and strength; another united simplicity with elegance; a third added lightness and beauty; and a fourth preserving truth of proportion and unity of combination, loaded itself with ornament, and carried the florid as far as Grecian simplicity permitted. Much was gained, and something lost, by these changes. While architecture assimilated itself more to the wants of man, and descended from the gigantic and the stupendous to the graceful and the serviceable, the artists who wrought the change seem to have sacrificed durability to beauty. Such frail materials as the forests present were scorned by the architects of the Pharaohs; they knew that wood must soon yield to time, if it succeeded in escaping fire, and with perhaps the terrors of invaders before their eyes, they employed no perishable materials, but made use of enormous slabs of stone, on which fire could take no hold, and which the hurried efforts of enemies could not overturn. The Greek architects had either more faith in the durability of their materials, or the stability of their empire. Less massive structures, and roofs of polished cedar, plated over with marble, no doubt were pleasing to the sight, and when adorned with statues of gods, and pictures of noble actions, could not fail to produce a strong effect on the mind. Yet to those who reflected upon the vicissitudes of nations, the whole must have appeared unsubstantial, nay, shadowy. The roofs could not fail in time to yield to the influence of the elements, and when the frail covering was injured or swept away, the rain would descend without obstruction into the

walls, and sap the vigour of the cement, and loosen and destroy the firmest masonry. This is no visionary fear; it has all come to pass; the enemies of Greece prevailed; her statues of ivory and gold tempted the spoiler by the richness of the materials; her groups of marble lured the more tasteful of the conquerors, and when her gods were gone and her strength had decayed, the roofs of her magnificent temples were neglected, and—behold the difference of the architecture of Egypt and Greece; many of the national buildings of the former are still unbroken and entire; none of the structures of the latter exist in a complete state, though raised a thousand years perhaps after the other, they have sunk gradually to ruin, and will soon exist only in the labours of the draughtsman and the engraver.

But the architecture of Greece may be called immortal, compared to the brief existence which time allotted to her noble paintings, the fame of which has filled the world. He who works in marble or granite may have some chance of surviving in his productions for thousands of years; but he who commits his fancies to fine colours, spread out upon wood or cloth, cannot hope to live visibly for more than a few centuries. "How long," said Napoleon, to the artist David, "will a picture last?" "For some five hundred years, Sire," was the answer. "Bah!" exclaimed the Emperor, "a fine immortality!" That the whole peninsula of Greece, with her numerous isles, and colonies in Asia, were filled with pictures of the highest excellence, we have the testimony of poets, historians, and travellers. Their descriptions are generally rapturous, rather than particular; they dwell more upon the effect, than the means by which that effect was produced, and though they trace architecture and sculpture to the banks of the Nile, they have been less explicit with painting, and left us rather to consider it as a direct emanation of Grecian genius, than a light brought from a far land. Nor is its parentage of much moment. The idea only could come from the Nile: there painting was in a state rude and uncouth, though splendid enough in its colours: the human form had the rigidity of a corpse; and instead of natural expression and agreeable light and shade, all was darkly undefined, or brightly splashed with costly hues, like the landscapes on a Chinese vase.

Of the state of painting, in the earlier days of Greece, we can give no satisfactory account: we may safely surmise, however, that it marched side by side with sculpture, from rudeness to beauty, and soon freed itself from the bounds into which architecture threatened to confine it. If

we dared to imagine, with some intelligent writers, that in the pictures of the Mexicans we behold the early paintings of the Greeks, the character of their first groupings might soon be drawn; but though demi-barbarous both, it appears to us that the genius of the two nations were essentially different. We are told, indeed, that Cortes and his companions viewed with admiration cotton stuffs so fine and of such delicate texture as to resemble silk; pictures of animals, trees, and other natural objects, formed with feathers of different colours, disposed and mingled with such skill and elegance as to rival the works of the pencil in truth and beauty of imitation: nay, farther, that some painters in the train of the Mexican chiefs, set up their easels, and delineated, upon white cotton cloths, figures of the ships, the horses, the artillery, the soldiers, and whatever else attracted their notice as singular, and even attempted to express the evolutions of war; the rushing of armed horsemen, and the smoke, and sound, and effect of the artillery. But neither in the carvings nor paintings of the Mexicans is poetry or science present: in this those rude efforts of the two nations differ; something of the presence of divinity was visible in the sentiment of the unshapeliest work of Greece: in the best works of the Mexicans there is not even the dawn of sentiment; they trusted for effect to rich colours and the variety of the materials. Time and inquiry have confirmed the sentence of the historian,—that though the Mexicans with much skill and ingenuity represented men, animals, and other objects, by such a disposition of various coloured feathers, as produced the effect of light and shade, yet the best efforts of their art are uncouth representations of common objects, or very coarse images of the human and some other forms, destitute of all grace and propriety. In their grotesque compositions there is more of the Egyptian than of the Grecian: the latter never appeared without poetry and feeling, and we must reject as fabulous or fanciful all the points of resemblance perceived by the ingenious and the curious.

It is perhaps a safer way to describe the paintings of Greece by a reference to the efforts of sculpture, in what is called flat relief; a species of production which partakes of the nature of both, without sharing in the high qualities of either. We are the more inclined to do this from observing that the descriptions given by Pliny and Pausanias, of the pictures of Greece, show a close similarity both in character and subject with not a little of the sculpture which has survived. We are not without suspicion too, that the pictures were generally without

landscape or scenic backgrounds; nay, some have gone so far as to assert that the divine painters of Greece had not discovered the art of uniting their separate figures and groups into one grand and harmonious action. The resemblance to sculpture was therefore the closer; and perhaps we are describing the copy in marble of an ancient picture, when we relate the impressions which some of the still existing groups and reliefs make on our minds. On a sarcophagus, now before us, and lately discovered by Sir Pulteney Malcolm, in Crete, there is sculptured, in low relief, one of those scenes on which poets laid out their fancy, and painters lavished their colours. The subject is the triumphant return of Bacchus from India; what this had to do with death and the grave let the learned explain. A naked youth, stooping under a wine skin, accompanied by a musician, leads the procession; an elephant follows, with three girls on its back, playing on the double pipe and cymbals; Silenus, sufficiently intoxicated, is borne after by two youths, who seem not unconscious of the weight, while a satyr follows, striking a tambourine, and actually leaping into the air with delight. A male and female centaur succeed; they are *side* by side; "one seems woman to the waist and fair, but ending foul," the other has his brows bound by vine leaves, and seems in a passion which his female comrade strives to soothe away by throwing her arm around his neck; the empty cup depending from her fingers intimates that wine has something to do with the wrath which agitates him. This is more fully intimated by the action of the closing group: Bacchus appears all youth and beauty, grave rather than joyous, in a splendid car, on a pannel of which a youth and satyr are contending; the left hand of the god supports a trophy, while the right hand protects a trembling faun, his companion in the car, at whom the exasperated centaur seems about to throw a wine-flagon: the fear of the one and the surly wrath of the other are well expressed. Two men, on one end of the sarcophagus, seem disputing about a child which they are bearing away in a basket; while on the other end two cupids are engaged in the task of putting a tipsy satyr to bed; a blanket is suspended between two trees; the urchins have their friend on their shoulders, and are striving on tiptoe to heave him up, while a quiet smile is playing over his brows and in the corners of his mouth at their fruitless endeavours. All this seems more akin to luxurious painting than to the simple gravity of sculpture.

This sarcophagus seems of great antiquity. The subject sculptured upon it was not peculiar

to Greece. We are told by Diodorus Siculus that in the temple of Belus, raised by Semiramis, at Babylon, there were paintings of hermaphrodites and centaurs, and other strange and not very poetical creations: the same writer also informs us, that on a bridge which the same queen threw over the Euphrates, there were "not only single figures of animals represented in colours, but they were also combined in groups: one, a hunting piece of considerable length, wherein the queen herself was represented on horseback, throwing her dart at a panther; and near her Nimus striking a lion to the earth with his spear." These works were painted on the bricks previous to burning: enamel seems to have been well known to ancient artists.

No one has hitherto succeeded in removing the veil which time has thrown over the origin and progress of painting in Greece. Of all the treatises written on art by Apelles, Protogenes, and Perseus, not one passage has descended to us, and we are obliged to accept the remarks of critics, and the doubtful testimonies of historians, in place of the narratives of scientific and skillful men. The labours of Penelope, and the amusements of Helen, may be the inventions of Homer, and the legend of the Corinthian maid who traced, by lamp-light, the shadow of her lover on the wall, may be a matter of fancy. We descend to firmer ground when, with Pliny, we ascribe the production of outline to Saurias, and of colour to Cleophanes of Corinth; to these Eumarus, the Athenian, and Cimon, of Cleona, added draperies and action, with natural delineation of veins and muscles. To those artists no one has been so bold as ascribe a period of either birth or death. They were followed by Bupalchus, who, seven hundred years before Christ, painted, with so much success, the battle of the Magnes, that Candaules, king of Lydia, thought it cheap of its weight in gold. The fine arts were interrupted by the Persian invasion: when the battle was fought and the victory won they shone out in all their lustre. Panæus, brother of Phidias the sculptor, painted the battle of Marathon, on the walls of the Portico at Athens, and into the vicissitudes of the fight introduced the chief leaders, Greeks and Persians: beauty of colour and harmonious light and shade had not yet risen in all their strength. Mycon seems to have surpassed Panæus: he painted the battle of the Athenians with the Amazons: likewise the war betwixt the Centaurs and Lapithæ, in which Theseus was represented in the act of slaying one of the Centaurs: the victory was left in doubt.

Timagoras of Chalcis excelled Panæus, and

bore away the prize at Delphos; he in his turn was surpassed by Polygnotus of Thasos, a man of uncommon genius and application. He was the first who added gaiety to action, and took austerity out of female looks; his fame reached Rome, and centuries after his death inspired Lucian with his idea of a perfect woman. "Polygnotus," says he, "shall open and spread her eyebrows, and give her that fine glowing decent blush which so inimitably beautifies his Cassandra; he likewise shall give her an easy flowing dress, with all its delicate wavings; partly clinging to her body, and partly fluttering in the wind." These words might be applied to some of the best pictures of Reynolds or Lawrence. The works of Polygnotus were numerous, and chiefly historical. At Platæa he painted Ulysses destroying the suitors, and the expedition of Onatas to the Argive Thebes; they adorned the temple of Minerva, and were in the vestibule: he was also employed to ornament the Pœcile at Athens, and the Public Hall at Delphos. The pictures at the latter place made a strong impression on Pausanias, who in his Phocis displays their merits and meaning in a long and interesting description.

The first of these paintings represented the destruction of Troy and the departure of the Greeks for their native land. Menelaus stands on the prow of his ship: his pilot Phrontis distributes oars or poles; boys and seamen are conversing in groups: on the shore Polites and his brother warriors are taking down the tent of Menelaus. Briseis too is introduced, near her is Diomed, nearer still Iphigeneia: nor is Helen forgotten; soldiers are in a group admiring her, and she is seated: Panthalis stands beside her while her other handmaid Electra fastens her shoes. "Here too," says Pausanias, "Epeus is painted throwing down the walls of Troy from their foundations. And the only thing above these is the head of the horse Durateus. Polyperetes, likewise, the son of Pirithous, is painted having his head bound with a fillet. Acamas, the son of Theseus, stands by him with a helmet on his head, and a crest on the helmet. Ulysses too is present, and wears a coat of mail. Ajax, the son of Oileus, approaches with a shield to the altar, in order to swear before he offers violence to Cassandra. But Cassandra sits on the ground, holding the wooden image of Minerva, which she tore from its basis when Ajax drew her from her supplications at the altar. The sons of Atreus likewise are painted with helmets on their heads. But on the shield of Menelaus there is a dragon, viz. the one that appeared as an omen during the sacrifice at Aulis.

These administer the oath to Ajax. Opposite to the horse, Neoptolemus is beheld near Nestor slaying Elacus. This Elacus, whoever he was, resembles a man nearly expiring: Neoptolemus too strikes with his sword Astynous who has fallen on his knees, and who is mentioned by Lesches. Polygnotus, indeed, is the only one of the Greeks that has represented Neoptolemus still continuing to slay the Trojans; and his design in this was that the whole picture might correspond to the tomb of Neoptolemus. An altar too is painted and a boy embracing it through fear. On the altar there is a brazen coat of mail: Laodice stands behind it: nigh Laodice there is a stone pillar, beside which Medusa sits on the ground holding it with both hands. One may rank Medusa among the daughters of Priam, who has read the ode of Himeræus. Near Medusa there is an old woman with her hair shaven to the skin; she holds a naked infant on her knees. With respect to the dead bodies in the picture, one of them is Pelias, who is naked and is thrown on his side; beneath him Eioneus and Admetus lie, having on their coats of mail. Lesches informs us that Eioneus was slain by Neoptolemus, and Admetus by Philoctetes. Under the laver, Polydamas lies, who was slain by Ulysses. Nigh the dead stands Antenor, and close to him Arino his daughter; she holds in her arms an infant boy. These are painted with sorrowful countenances. Servants are placing a chest and other furniture on an ass; and a little boy sits on the ass. In this part of the picture there is the following lines by Simonides:—

"The artist Polygnotus, for his sire  
Who claims Agriophon, in Thebes born,  
Painted the captured tower of Troy."

In the works of Polygnotus, as described by Pausanias, artists, and sensible ones too, have perceived immense labour, high talents, but no idea of composition, perspective, or light and shade. "Each figure," says one of these authorities, "had its appropriate action, consistent with its history and character, but no connexion in lines with its neighbour; and that the observer might be at no loss of time in considering whom they represented, the painter had placed a name to every figure. They were arranged in rows, beside or over each other; and Pausanias, in describing them, begins at one end, and proceeds with an individual enumeration of them to the other, and then speaks of other figures over these; but whether they diminished in size does not appear." Much of the blame which the critic attaches to the painter seems to be attri-

butable to Pausanias. He was anything but a clear describer; yet from the quotation given we may perceive, that though the deeds of many days were, drama-like, brought forward at once, and though the figures were scattered, the destruction of Troy was stamped legibly on the whole; nay, some of the groups had an episodic interest of their own, while at the same time they composed well with the impatience of Menelaus to begone, the lingering delay of Helen with her handmaids, and the burning vengeance of Neoptolemus, who desired to slake the burning ashes of Troy with blood. Let us, with such light as Pausanias affords, look at one or two more of the paintings of Polygnotus, and see whether the opinion of the critic is sustained.

The second picture by Polygnotus at Delphes represents Ulysses descending to Hades, to consult the spirit of Tiresias about his return to Ithaca. A river, the Acheron, is painted, edged with reeds, gloomy, and containing fishes, which seem shadows. The ship of Charon is in the stream, and Charon himself is there; nigh him an unfilial son is strangled by his father; also, there is one punished who committed sacrilege. Eurynomus, too, is not distant, who, according to the Delphic interpreters, is one of the demons who eat the flesh of the dead, so as to leave the bones white and bare. His colour is between azure and black, and is like that of flies which infest meat. He shows his teeth, and sits on the skin of a vulture. Perimedes and Eurylochus carry victims, black rams. Ariadne sits by the Acheron on a rock, and looks at her sister Phædra; Chloris reclines on the knees of Thyia. The former was married to Nereus, and the latter was the mistress of Neptune. Clymene sits with her back to Thyia. In the more interior part of the picture is Megara, who was the wife of Hercules. Above the heads of these women is the daughter of Salmoneus sitting on a stone. Eriphyle stands near her, and raises the extremities of her fingers, through her garments, to her neck. You may conjecture that she holds a necklace in that hand, concealed in the folds of the garment. Elpenor is represented above Eriphyle and Ulysses kneeling, and holding a sword over the trench, to which the prophet Tiresias approaches. Anticlea, the mother of Ulysses, is seated nigh him on a stone. Elpenor is covered with a mat made of bulrushes, after the manner of sailors. Theseus and Pirithous sit on a throne below Ulysses: the former holds his own sword and that of Pirithous in both his hands; the latter looks at the weapons, and seems indignant that he has no sword to aid him

in his daring enterprise. The conception of this picture is at once poetic and historic. The painter desired to represent the chiefs of his country; and the descent of Ulysses into the shades enabled him to bring together the heroes of old, and the leaders of latter times. It seems not to have been wanting in all the higher qualities of invention, composition, and expression. — The third great picture of the series merits examination. It is less stern in character than its companions. Grecian mind and feeling is emblazoned on every part. The artists of that great people found all their subjects at their own threshold.

After these Polygnotus painted the daughters of Pandarus. Through the anger of the gods their parents died early; and thus becoming orphans, they were educated by Venus. They received prudence and beauty of form from Juno, tallness from Diana, wisdom in household duties from Minerva, and Venus, to render all those gifts beneficial, ascended to heaven and obtained for them happy nuptials from Jupiter. But the Fates were unpropitious. During the absence of Venus they were seized by the Harpies, and delivered over to the Furies. Polygnotus crowned them with flowers, and represented them playing with dice. Nigh them Antilochus stands with one of his feet on a stone, and holding his head with both his hands. Agamemnon is close beside him, leaning with his left arm on a sceptre, and holding a wand in his hands. Protesilaus sits looking at Achilles, and Patroclus stands above him. All these, save Agamemnon, are beardless. Iasius appears as a youth; he is endeavouring to take a ring from the finger of Phocus. The latter lost his life through the treachery of Peleus, and the ring is taken as a pledge of friendship in death. Mæra is sitting on the ground; Actæon and his mother are beside her. The latter holds a faun in her hands, and sits on the skin of a hind. A hunting dog is near them, to intimate the fate of the youth. In the lower part of the picture, Orpheus sits with a harp in his left hand; and in his right the leaves of the willow tree, taken from a grove sacred to Proserpine. The figure of Orpheus is Grecian; and neither his garment, nor the covering on his head, is Thracian. Promedon, who loved all kinds of music, and Schedias, who led the Phœnicians to Troy, and Pelias, whose hair and beard were alike hoary, and blind Thamyris, in appearance humble and abject, with a beard thick and long, are all close to Orpheus. At the feet of Thamyris lies a lyre, which seems to have been dashed down; part of the frame is broken, and the chords are burst. Olympus, in the

flower of youth, stands in the attitude of a listener, and holds a pipe in his hands.

“If you look,” says Pausanias, “at the upper parts of the picture, you will see, in a continued series, Salaminian Ajax next to Actæon; and afterwards Palamedes and Thersites playing with dice, which were invented by Palamedes. The other Ajax is looking at them while they are playing; his colour is that of a seafaring man, and his body is yet moist with the foam of the sea. Polygnotus seems to have collected the enemies of Ulysses into one place. The reason why Ajax the son of Oileus hated Ulysses was, because the latter advised the Greeks to stone Ajax to death for his daring wickedness towards Cassandra. I know too, from the Cyprian verses, that Palamedes was drowned when fishing, by Ulysses and Diomed. Meleager the son of Æneus is painted, and appears to be looking at Ajax. All these, except Palamedes, have beards. In the lowest parts of the picture, after the Thracian Thamyris, you will see Hector sitting with both his hands on his left knee, and exhibiting the appearance of a man oppressed with sorrow. After him is Memnon, sitting on a stone; and close by him is Sarpedon, leaning with his face on both his hands. But one of the hands of Memnon is placed on the shoulder of Sarpedon; and all these have a beard. In the robe of Memnon, too, birds are painted; and these birds are called Memnonides. The people of the Hellespont say that these birds, on stated days in every year, fly to the sepulchre of Memnon, dig up every part about the tomb that is void of trees and grass, and then sprinkle the whole with their wings, which are wet in the water of the river Æsepus. Near Memnon, who was king of Ethiopia, stands a naked boy of that country. Paris stands a beardless youth; he is clapping his hands, after the manner of rustics, and you may conjecture by his clapping that he calls Penthesilea. Penthesilea is at no great distance, looking at Paris. She appears to despise him. Her figure is that of a virgin, with a bow like those of Scythia, and with the skin of a leopard thrown about her shoulders. A virgin in the flower of youth, and one of more advanced age, carry water in earthen urns full of holes: they represent the uninitiated. Above them are Callisto, and Pero the daughter of Neleus. A spousal gift of an ox is demanded by Neleus of Iphiclus for his daughter. Callisto has the skin of a bear for her couch-covering. Nigh these the painter has represented a precipice, to the summit of which Sisyphus endeavours to roll a stone. In the same part of the picture an old man, an old

woman, and a boy are seated. The old woman is pouring water into an urn. It appears to me that these are persons who despised the Eleusinian mysteries. Tantalus, too, is there, suffering those punishments mentioned by Homer, and terrified lest a stone which hangs over his head should fall on him. It is evident that Polygnotus followed Archilochus in this. So numerous are the figures, and such the elegance of the picture, which the Thasian artist painted."

Finer unity of parts, more artful grouping, and a happier distribution of light and shade, may be claimed for succeeding painters, but Polygnotus seems to have been one of the first who brought high imagination to the service of the muse of art. Pliny indeed says, that before Apollodorus no picture had been produced which a man might take pleasure in looking at for any length of time. Pausanias seems to have thought differently; and we owe to him the almost sole description of those great masterpieces of Grecian genius. Zeuxis succeeded Apollodorus. He endeavoured to unite the simple and vigorous style of Polygnotus with graces all his own. He took Homer for his model in heroes, and is supposed to have stumped them with that god-like dignity of expression which sculpture had already bestowed. The simplicity of manners in his day was favourable to his profession. When he painted the picture of Juno for her temple at Agrigentum, he caused all the most beautiful maidens of the city to stand before him naked, and selecting five of the most lovely, he combined their charms in the picture of the goddess. It was not in outward loveliness alone that he sought to excel in the figure of Penelope; he expressed the high qualities of her heart and mind. His Jupiter throned among the gods, and his Hercules strangling the serpents, a subject revived by Reynolds, are mentioned among his noblest works: but his youthful wrestler was his own favourite; he wrote underneath it, that it would be easier envied than equalled. His vanity was equal to his genius. He caused his name to be wrought in gold on the border of the garment, and refused to work for money, saying his pictures were above all price.

In talent and in vanity, Zeuxis found a rival and follower in Parrhasius the Ephesian. He had a fine eye for proportion. He made his outlines more visible than his compeers, and sought to charm by graceful action and softness of colouring. Euphranor, a brother artist, said the Theseus of Parrhasius appeared to have lived on roses. This has induced one of our critics to insinuate that the picture wanted substance and colour. When Fuseli talked of Rubens's

hillocks of rosy flesh, he brought no charge of weakness. Perhaps the hue of the hero was too womanly, and wanted vigour; yet the painter might have desired to intimate the elevation of Theseus among the gods. He styled himself Parrhasius the delicate, claimed descent from Apollo, wore a robe of purple, a garland of gold on his head, carried a staff with golden tendrils, and bound on his sandals with golden straps. To enable him to maintain this state, he charged high prices for his works. Nor did the charms of his pictures diminish by time. For his Chief Priest of Cybele the emperor Tiberius gave sixty thousand sesterces. He was excelled by Timanthes, in a picture representing Ajax in the award to Ulysses of the armour of Achilles. "It is true history," still exclaimed the exasperated artist; "Ajax is overcome a second time by one unworthy of such honour!"

Of Timanthes little is said. He excelled in vigour of imagination, and loved subjects of a kind vast and sublime. He painted gods, and heroes, and giants. In a picture of the Cyclops he expressed magnitude by making a satyr measure his colossal thumb with a thyrsus. One of his portrait pictures existed in the temple of Peace during the days of Pliny, who observed, "It is said to be so perfect and so full of majesty, that it appears to comprise everything desirable in the art of painting." The pictures of the Greeks were, as all true pictures are, an union of imagination and nature. The latter corrected the former, and communicated to its conceptions the hue, and the aspect, and the language of life. "Behold," said Eupompus the painter to the sculptor Lysippus, showing him a multitude of people passing by, "behold my models! From nature, not from art, must the artist hope to attain honour and extend the limits of his art." But then a painter was required in those days to be an accomplished person. The history of his country was his study; he sought images of grandeur or of beauty in tradition and in poetry. The sons of the princes of the earth handled the chisel and the pencil, and sought instruction in arts which brought fame and honour. Pamphilus the Amphilopolitan united literature with science, and his example was followed by all who felt the inspiring effect which they mutually exercise.

Apelles studied under Pamphilus; he is called the prince of ancient painters. The station which antiquity assigned him seems not to have satisfied Fuseli, who ingeniously labours to lower him a little. "The name," he remarks, "of Apelles in Pliny is the synonym of unrivalled or unattainable excellence; but the enumeration of his works points out the modification

which we ought to apply to that superiority. It neither comprises exclusive sublimity of invention, the most acute discrimination of character, the widest sphere of comprehension, the most judicious and best balanced composition, nor the deepest pathos of expression. His great prerogative consisted more in the union than the extent of his powers; he knew better what he could do, what ought to be done, at what point he could arrive, and what lay beyond his reach, than any other artist. Grace of conception and refinement of taste were his elements, and went hand in hand with grace of execution and taste in finish; powerful, and seldom possessed, singly irresistible when united." Fuseli was an artist of daring conception; he delighted in the tremendous and the extravagant, and affected the grand and the sublime. But who will measure his merits by the dignity of the subjects which he selected? There is more of moral grandeur in the Mouse of Burns than in the Creation of Blackmore. A humble, a simple theme is lifted to heaven by a true genius; and I see nothing in the names of the pictures attributed to Apelles to justify the depreciating estimate of Fuseli: besides, those who called him prince of painters saw the wonders of his hand; he who sought to lessen him never beheld a line which he drew, or saw him otherwise than through the stained glass of his own disordered fancy. If the people of old were right in naming Homer prince of poets; who can question their judgment in their praise of Apelles?

There was true greatness of soul in this illustrious painter. Men said he was surpassed by Amphion in disposition, by Asclepiodorus in proportion, and by Protogenes in happiness of handling; and though others supposed that in character and combination he excelled all, he seems neither to have been stung by censure nor uplifted by applause. He heard that Protogenes, his most gifted rival, had become poor; he sailed to Rhodes to see him, and purchasing several of his pictures, told the people of that isle that he would carry them to Greece, and sell them for the work of his own hands. They perceived the worth they had overlooked at once, and raised Protogenes to rank and fortune. There is something romantic in this. Nor is this all. The story of their friendly contest with the pencil is no fiction. When Apelles entered the studio of the Rhodian, the latter was absent; the visitor asked for a pencil, to show, as Prior rhymed it,

and at one stroke described a true and harmonious circle. When Protogenes saw this, he confessed the presence of a master; but taking his colours, shaded it so delicately and naturally, "that it seemed at once the egg of Leda," says the bard, "or the apple of Paris, or the breast of Chloe." The tablet found its way to Rome, and was there examined by Pliny; it seemed a large blank surface, till on close inspection the delicate lines grew visible. The drawings were of different colours, and were imagined to contain some mysterious principle of beauty, like that which Hogarth discovered in the winding or serpentine line, such as may be seen in the bloom of a tulip, or in the wreathings of a shell.

The achievements of Alexander became the theme of many of his pictures; for the painter was the friend rather than subject of the hero; and received many proofs of his attachment. He was visited by him, enriched by him, and when Apelles was observed gazing with more than an artist's admiration on the charms of Campaspe, he bestowed her upon him—a gift of the worth of which both were sensible. "Of Alexander the Great and his father Philip," it is observed, "the portraits which he painted were very numerous, some single, and some accompanied by other figures. One in the temple of Diana at Ephesus, of Alexander launching thunder, is highly extolled for its effect and the boldness of its relief, 'the hand which was raised appearing to come forward, and the lightning to be out of the picture.' In another of the same king, he was represented in a triumphal chariot; near him the figure of War, with his hands tied behind his back. This and another Alexander, accompanied by Castor, and Pollux, and Victory, were preserved by Augustus in the Forum." Other works are mentioned, historical and half historical, as Lawrence called his pictures half fancy, half portrait. Of these, Clitus on horseback, armed and bareheaded, in the act of receiving his helmet, Archelaus with his wife and daughter, Megabysus, priest to Diana at Ephesus, sacrificing in his pontifical robes, Antigonos king of Syria, and Antigonos the father of Demetrius Poliorcetes, are the most remarkable, as works reflecting living life; while Diana and her nymphs at sacrifice—Neoptolemus on horseback discomfiting the Persians—Hercules, with his back turned toward the observer—a Horse so lively and so real that it caused living horses to neigh—and last, and most celebrated, Venus rising from the sea, are remembered amongst his works of imagination.

Painting rose to its epic height under Apelles. He seems to have combined all that could

*"How painters write their names at Cos;"*

command, or excite, or astonish in his pictures. We must accept his universal fame as a full proof of his superiority, in spite of the remarks of modern professors. Aristides of Thebes, inferior to Apelles in harmony and grace, surpassed him in delineating the passions. It is said of the Suppliant, whom he painted, that his look was intensely earnest, and his voice seemed to escape from the picture. He loved painful subjects. He painted a sister dying for love of her brother; and a mother, mortally wounded in the bosom, endeavouring to prevent her infant sucking blood with her milk. He now and then touched historical subjects. His battle between the Greeks and Persians contained a hundred heads, and he was paid ten pounds' weight of silver for each. His Chariot Race, too, was widely admired. "You would almost think," said Pliny, "that the wheels were in motion, such was the energy of action in the picture." Other eminent men maintained the glory of Grecian art. Asclepiodorus excelled in symmetry, and Protogenes in beauty of finish. The compliment paid to the latter by the accomplished Demetrius ought not to be forgotten. He refused to assault Rhodes on the side where the painter's studio stood; and when he took the city, and the chief men entreated him to spare the pictures of their admired countryman, he made answer, that he would sooner destroy the images of his own ancestors than touch the productions of Protogenes.

There is a sad deficiency of technical knowledge in the accounts which have descended to us of Grecian painting; nor is there so much detailed or vivid description as we could wish. The same may be said of sculpture; but we are not therefore to conclude—as some have not hesitated to do—that the latter, of which we fortunately see so much, excelled the former, of which no specimens have survived. For anything that can be gathered or surmised from ancient writers, we need not pause before we say that all the secrets of light and shade, and beauty of colours, and harmony and unity of composition, which distinguish modern art, were familiar to the great painters of Greece. The writings of both Pliny and Plutarch abound in passages intimating this. "The hand of Alexander," the former observes, "appeared to come out of the picture." "Painters," says the latter, "increase the brilliancy of light colours, by opposing them to dark ones, or to shades." Pliny speaks even more decisively. "The art assumed new powers, and discovered or invented light and shadow; by graduating which, the colours are alternately heightened or kept down.

Afterwards splendour was added, which was different from light, and which, because it was a mean between light and shade, they called tone, and the union of the colours, and the transition from one to another, they called harmony."

Those who suspect, from the want of direct and visible evidence, that the paintings of ancient Greece failed to equal those of modern Italy, can entertain no such doubts regarding the excellence of the sculpture; for nothing has yet been created which rivals the grace and dignity of the Venus or the Apollo. It is true that these magnificent works, and others of equal beauty, are the consummation of ancient art; while it may be averred that modern art is still living, and producing groups and statues. But from what is, we may imagine what will be. We want both the austere simplicity and poetic elevation of the productions of Greece; our forms are less pure, our sentiments less ethereal; and though we excel them in the picturesque, we are not sure that they thought it worthy of study.

The sculptors of Greece borrowed perhaps the inanimate body of their art from Egypt or Syria; they endued it with life, and gave it beauty of form and elevation of sentiment. Dædalus seems to have been one of the first who asserted the dignity of sculpture. He wrought chiefly in hard wood; and when he found the material unsuitable for the expression, he made the heads of stone. A naked Hercules from his chisel was seen by Pausanias, who remarks that "his works are indeed rude and uncomely in aspect; but yet they have something as of divinity in their appearance." It is supposed that some of the works, or copies at least, of that artist still exist. "In the British Museum," says Flaxman, "as well as in other collections of Europe, are several small bronzes of a naked Hercules, whose right arm, holding a club, is raised to strike, whilst his left is extended, bearing the lion's skin as a shield. From the style of extreme antiquity in these statues, the rude attempt at bold action which was the peculiarity of Dædalus, the general adoption of this action in the early ages, the traits of savage nature in the face and figure, expressed with little knowledge, but strong feeling, by the narrow loins, turgid muscles of the breast, thighs, and calves of the legs, we shall find reason to believe that they are copied from the Hercules of Dædalus." The Gnossians possessed a Chorus in white stone, made by the same artist for Ariadne, from the eighteenth book of the Iliad, where youths and maidens dance hand in hand. Endæus followed and made the Minerva seen by Pausanias at Athens. From this figure it has been surmised that the

latter Minervas caught their shape and sentiment. There is, however, no little monotony of action and expression in the old divinities of Greece. Jupiter, Neptune, and others, have the selfsame form and action of the Hercules by Dædalus; the difference lay only in the accessories: Jupiter held a thunderbolt, Neptune a trident, and Hercules a bow. But this monotony is accounted for when we think of the religion of the land. The shape and action first bestowed on the gods became the precedent for all succeeding sculptors. A nobler expression, and more scientific beauty of form, were bestowed; but the old attitude was adopted in all single statues. It is supposed that the colossal busts of Apollo and Hercules in the British Museum are very early works; indeed, Flaxman says, they were probably sculptured by Depenis and Scyllis for the Sicyonians.

The harmony of outline seems to have been little studied by the first artists. Cleanthes the Corinthian is said to have discovered or practised it: Telephanes of Sicyon used other lines within the outline to express the workings of the body and limbs: Cimon Cleoneus invented the oblique representation of forms; and added the veins, and multiplied the folds in the draperies. These discoveries ushered in Phidias, who performed for marble all that Apelles did for colour. That illustrious artist gave to sculpture the ease and dignity of poetry. He found his art stiff in its sublimity, ungraceful in its simple beauty, and deficient in natural freedom, though not in loftiness. "His superior genius," says Flaxman, "in addition to his knowledge of painting, gave a grandeur to his compositions, a grace to his groupes, a softness to flesh, and a flow to draperies unknown to his predecessors; the character of whose figures were stiff rather than dignified: their forms either meagre or turgid, the folds of drapery parallel, poor, and resembling geometrical lines, rather than the simple but ever varying appearances of nature." He kindled his genius at the fire of Homer; and thought it his best praise to embody the poet's sentiments and give form to his verse.

Of the works of Phidias we have very full and clear accounts. "His Athenian Minerva, and Olympian Jupiter at Elis," says Quintilian, "possessed beauty which seemed to have added something to religion—the majesty of the work was so worthy of the divinity." He adorned the Temple of Minerva on the outside with his compositions, executed by hands little inferior to his own: but he employed his own genius in the interior, in conceiving and executing that wondrous statue of the goddess which Greeks and Romans alike united in admiring. It was a standing

figure, thirty-nine feet high, composed of ivory and gold, holding a Victory six feet high in her right hand, with a spear in her left, and a simple tunic reaching to her sandalled feet. She had her helmet on, and Medusa's head on her ægis: her shield was adorned with the battle of the gods and giants, the pedestal with the birth of Pandora. Plato tells us that the eyes of the goddess were of precious stones. The sculptures all around the temple related the history, true or fabulous, of Greece. The classic ground of Phidias was the land he lived in: he sought in no far country for subjects for his chisel: our ideas of classicity seem different; when a British artist embodies a Latin song or a Grecian fable, a hundred tongues exclaim classical: they are silent when beauty, and elegance, and dignity, are found in British song or British history. Phidias held all to be classical which was poetic.

The Jupiter of Elis was still more celebrated than the Minerva. "He was seated on a throne," says Flaxman, "his left hand holding a sceptre, his right extending over the Olympian conquerors, his head crowned with olive, and his pallium decorated with beasts, birds, and flowers. The four corners of the throne were dancing Victories, each supported by a nymph tearing a Theban youth. At the back of the throne, above his head, were the three Hours or seasons on one side, and on the other the three Graces. On the bar between the legs of the throne, and the panels or spaces between them, were represented many stories:—the destruction of Niobe's children, the labours of Hercules: the delivery of Prometheus: the garden of the Hesperides, with the different adventures of the heroic ages. On the base, the battle of Theseus with the Amazons. on the pedestal, an assembly of the gods, the sun and moon in their cars, and the birth of Venus. The height of the work was sixty feet; the statue was ivory enriched with the radiance of golden ornaments and precious stones, and was justly esteemed one of the seven wonders of the world." Other statues of astonishing beauty are mentioned among the works of Phidias: a Venus, placed by the Romans in the forum of Octavia; a statue of an Amazon, called Euknemon, from the beauty of her leg; and two Minervas, besides her of the Parthenon, one named Callimorphus, from the beauty of its form. Flaxman conjectures that the fine statue in marble of that goddess in Hope's gallery has been copied by some skilful hand from the bronze statue by Phidias; it resembles closely the reverse of an Athenian coin, and has the graceful and majestic air observed in the other works of the illustrious sculptor.

The glory of Greece was at its height both in arts and in arms during the days of Phidias: the whole land was filled with the trophies of war and with the statues of heroes and of gods: the eye, wherever it turned, was charmed with the loveliest or the noblest forms which the mind of man could conceive or his hand execute. The rudest hinds of Greece looked with reverence on those works, and serf and peasant wandered among groves of statues without injuring or even touching them. How different is the feeling for such works in England: iron rails and paid guards cannot protect the statues of our island from the barbarous hands of the people: they have no taste for the poetic or the grand: they confer a smile of approbation upon coarse representations of vulgar life and throw stones at whatever is beautiful or majestic. The Venus Aphrodite, by Alcamenes, or the Venus of Cnidos, by Praxiteles, would have fared ill among the rustics of Britain; in Greece and her isles they found only admirers. Praxiteles excelled in creations of youth and beauty. Many sailed to Cnidos to gaze at his Venus; of that goddess he formed two statues, one naked, the other draped; the Coons preferred to purchase the latter on account of its severe modesty; the citizens of Cnidos bought the other, and admired it so much as to reject the offer of king Niomedes to forgive them a large debt to have the honour of possessing such a miracle of genius. From his naked Venus it is generally surmised that the Venus de Medicis is derived.

Of the works of the succeeding great sculptors of Greece, some of high merit have descended to us without suffering much injury from accident or time. The gold and ivory creations of Phidias carried such temptations about them as the barbarian conquerors of Greece could not resist; the wooden figures of Dædalus and his successors, perished by fire; the brass or silver statues of Praxiteles or Polycletus were broken in pieces, melted and reproduced in current coin or capacious drinking cups; such is the fate of all works of art executed in too attractive materials. The Waterloo cannon, in the statue of Valour, may at some future day return to their original shape and use. The Discobolus of Nausides, admired for its firm and fine balance, has reached us; the dying hero of Ctesias, the admiration of antiquity has been discovered, too ingeniously we fear, in the Dying Gladiator. The graceful and delicate Hermaphrodite of Polycles has been diffused over Europe in casts. Scholars have perceived the Nine Muses of Philiscus of Rhodes, or those brought to Rome by Fulvius Nobilior, in the Muses of the pope's

collection, of which comedy is eminent for grace, and tragedy for grandeur. That the marbles of the exterior of the Parthenon are the work as well as the invention of Phidias, has been asserted by antiquaries in our own day: the colossal statues on Monte Cavallo, in Rome, bear the names of Phidias and Praxiteles, on their pedestals; the animated character of the group, as well as the style of execution, seem of the best days of Grecian art.

Other works of equal or superior beauty to these have been preserved, viz., the Fighting Gladiator, by Agasias, pronounced by Albata Fea to be Ajax son of Oileus; the touching group of Laocoon and his sons, the work of Apollodorus Athenodorus and Agesander of Rhodes; the Niobe and her youngest daughter, by Leopas; the Apollo of Belvidere, believed to be the Apollo of Calamis; the Venus de Medicis, found in the forum of Octavia, descended without diminution of beauty, it is believed, from the Venus of Cnidos. Of these the Apollo is the most godlike. "Admirable and sublime," says Flaxman, "as its beauty is, there is a reason which perhaps might render it less popular with the ancients than the moderns. Maximus Tyrius describes a statue by Phidias, very similar to this, but more in motion, discharging an arrow, or preparing to do so. There are traces of this statue in some ancient basso-relievos, and it is possible the stronger expression of Phidias's work, together with the authority of his name, might have diminished the public attention to Calamis in a comparative production." Nor should those noble reliques, the Elgin marbles, be forgotten; few of them indeed are perfect; heads, and hands, and feet have been miserably despoiled by time, nay, in some of them the surface is entirely gone: yet in the most time-worn and broken, such simple grandeur of conception, exquisite ease and nature of detail, and delicate skill of workmanship is visible, as justifies the admiration as well as money lavished upon them by the nation.

The architecture of the Greeks all but rivalled their statues and pictures; they found it rude and cumbrous, and they gave it beauty and grace; they added columns to the temple, and raised the ornamented roof, which caught the eye in the distance, shielded the worshippers alike from sun and rain, and preserved the walls from frosts and damps, and from the pressure of heavy snows. They divided it into orders, and assigned to each a proper duty; all their inventions had a meaning; their commonest ornaments spoke history, real or fabulous, to the beholder; they did nothing for the sake of effect only, yet effect was

never wanting. It must be confessed, however, that their system of architecture had its limits; to raise a lofty temple, enormous columns were required; these again demanded enormous blocks of stone for friezes and entablatures, and great wealth, as well as great power, was required to find solid masses of fifty or sixty tons weight, and lift them seventy feet into the air. It may be questioned whether any of the temples of Greece equalled in scientific combination of parts, or in lofty beauty, the cathedrals of St Paul's in London, and St Peter's in Rome; yet they certainly stood singly and alone in the preservation of that elegant and somewhat severe simplicity—the mark of every thing Grecian.

The unity of architecture, painting, and sculpture observed by the Egyptians in all their temples was followed for a time by the Greeks, till poetry came to the aid of the two latter and raised them to be principals rather than accessories. In Egypt, the temple surpassed the gods which it sheltered, or the paintings which it protected from the elements: in Greece, the temple soon became little more than an elegant case to contain statues which men worshipped as miracles of beauty, and paintings diviner still. No doubt the three were beautiful when united; but poetry gave wings to painting and sculpture which lifted them above their more mechanical associate. The great architects of Greece studied durability as well as beauty; they looked with scrupulous care to the firmness of the foundations, to the size and solidity of the stones, and to the nicety with which they were squared and united. They depended less on cements than on the geometrical skill with which one part sustained another; and there are examples of masonry where the blocks are built without mortar, no doubt from a fear that cement was liable to decay, and would perish sooner than marble. Grecian architecture has been revived in Britain, but it languishes though recommended by high talent, and, more influential still, wealth and rank. The ancient Gothic spirit is strong in our island; we are lovers of the lofty and the picturesque; an awe comes upon us while we walk in a Gothic abbey, but we survey the classic creations of Greece with a cold regard; they are not akin to our emotions, and our heart makes no response.

That the sculpture of Greece surpasses the art of all other nations, can be proved by all who choose to assert it. We need only point to some half dozen groups and statues, and ask what productions of our latter days can be compared to them? We find more action, indeed, and picturesque display, in some of the marbles of Italy; but then violent action and extreme

attitudes were alien to the simplicity in which all of Grecian growth was conceived. A modern warrior fights with ferocity in marble, an ancient warrior fought with grace; the ladies who live in our later art attract us as much by the nicety of their dress as by the beauty of their persons, the ladies of Attic sculpture charmed by their austere modesty, and by the exquisite symmetry of their forms. Equal decorum was observed in their representations of the gods: they stood with elegance, they moved with dignity; and when action was necessary, they performed it with a divine ease, which marked the godhead as much as their majesty of look did. Nor did the artists of Greece seem anxious to spread out their conceptions over a large space; all with them is put into as small compass as possible; they desired to be compact as well as simple; they finished all they touched with surprising nicety and care; the hands, the feet, and heads of their figures seem to have been looked at in every light, and polished to suit all sites and situations. While some modern marbles look hard and sharp in the plaster casts taken from them, the marbles of Greece look soft and round, and lose nothing of their beauty of character by change of material. That the paintings of the Greeks equalled their sculpture, we need have little hesitation in believing. We ought not to see, with some modern critics, the pictures of Athens in the daubings of Herculaneum, any more than behold the excellence of their sculpture in the chisellings on the column of Trajan or the arch of Constantine. The Romans inherited little of Greece save the sea and shore; they were not full heirs of her genius. They carried away multitudes of paintings, and statues by the thousand, and filled Rome with elegant spoil. They carved, too, and they painted, and imagined themselves the rivals as well as conquerors of the people of Attica. In some of their bas-reliefs there is good grouping, and in several of their statues both beauty and simplicity; but then the light by which they wrought was artificial and borrowed. Greece was the source of all their efforts, in poetry as well as art; they were imitators, not true originals.

Those who make the genius of Greece their study will find that her poetry and sculpture, her painting and architecture, are all akin, and marked with the same distinguishing qualities. The study of the ancient masters "will give the young artist," says Flaxman, "the true principles of composition, with effect and without confusion, to produce the chief interest of his subject by grand lines of figures, without the intrusion of useless, impertinent, or trivial

objects. By carefully observing them, he will accustom himself to a noble habit of thinking; and consequently choose whatever is beautiful, elegant, and grand, rejecting all that is mean and vulgar. By thus imbibing an electric spark of the poetic fire, he will attain the power of employing the beauty and grace of ancient poetry in the service of the establishment and morals of our own time and country." To enable the student to accomplish all this more effectually, he will act prudently in taking some poetic animation of his own to the task, lest he should find the "electric spark" of which the great sculptor speaks more of a figure of speech than a sure inspiration.

ON  
THE RISE AND PROGRESS  
OF  
THE FINE ARTS.

---

PART II.

CHRISTIAN.

WHEN Christianity rose, the heathen arts fell; not, indeed, at once, as Dagon did, but slowly and surely. Their spirit was touched, oracles became dumb, divine voices were no longer heard on Olympus, and Jupiter and Minerva gradually grew into figures of speech. But the fine arts would have sunk, had the star of Bethlehem never risen. It is true, that Christianity forbade bowing to gods of stone, and wood, and brass, and desired man to raise his eyes towards that Divine Being, the Unknown God of the heathen, who created and directed all. This would have purified art, rather than crushed it; painting and sculpture, taking a new direction, and inspired with a truer inspiration, would have wrought miracles worthy of the days of Phidias and Apelles: but time was not afforded for the change. Before the coming of Christ the northern nations of the earth, an unsummed and unknown race, had given intimations of their resolution to march towards the sun, and contend with those who called them barbarians for the vineyards and cornfields of Italy and Greece. In the days of the apostles this terrible march was begun; and though the warlike spirit of the early emperors, and the discipline of the legions, retarded or repulsed the Gothic nations for a time, they burst the decaying barriers of the empire at last, and science and letters were all but extinguished on the earth. They were neither softened by the harmony of verse, nor gladdened by the loveliness of sculpture or painting. Temples, statues, pictures, books, all were trodden relentlessly underfoot, in their tremendous march.

The spirit—the divine spirit—of Christianity, enabled it to survive this sad devastation; and

with it the hopes of science and letters remained. The fierce conquerors of all that was civilized or elegant rested themselves among the ruins of temples and cities; and with the wine-cup in one hand and the sword in the other, gave a sort of surly audience to the dauntless successors of the apostles, who came to tempt them with the joys of heaven, or alarm them with the horrors of hell. By some it has been reckoned miraculous that those rude and fierce chiefs who ruled the Gothic tribes, seated with one foot, perhaps, on the body of a mangled Roman, and the other on a broken statue—Apollo or Venus—should have listened, and that with emotion, to the first preachers of the word of God. But be it borne in mind, that the latter came neither as suppliants, nor rivals, nor enemies; they desired no share in their conquests, nor in their carousals; the kingdom which they revealed to them was not of this world; and thus opening up fresh sources of glory, the Gothic princes listened, and perhaps postponed the destruction of a temple or the burning of a city—for a day. There was something in the glory or the woe of a future state which suited the imaginations, and, in some measure, accorded with the natural belief of the Goths, and fitted their minds for receiving the sublime truths of the gospel.

Painting and sculpture aided largely in this beneficial conversion. The first missionaries, speaking the classic languages of Greece or Rome, were not understood by their northern audiences till they called in the works of the pencil and chisel as auxiliaries. A Christ on the Cross, a Virgin Mother, a Saint John in the Wilderness, the Raising of Lazarus, the Ascension, together with reliques of the early saints, all helped to relate the history and the hopes of Christianity, and impress it on their rude understandings. Nor were the barbarians reluctant hear-

ers: so anxiously did they look and listen, that when the first preacher of the Scriptures to the Irish struck unwittingly the iron-shod end of his crosier through the foot of one of the princes, the latter bore the pain with fortitude, from a belief that it was a sample of the truths which the other came to teach. We must not, however, imagine, that the paintings and carvings which the preachers carried about with them then, in the same way as a divine of our latter days bears his manuscript sermons, were works worthy of either science or art. They are, in fact, believed to have been coarse and rude in execution, with nothing of the genius of heathen Greece visible in them; and it is, moreover, very possible that they were the works of the missionaries. What renders this surmise probable is the fact, that in the palmier days of the Christian church those magnificent abbeys, the wonder and the envy of living architects, were chiefly imagined and designed by prelates, who did not think it beneath them to apply their talents in creations of usefulness and elegance. From whatever source those drawings and carvings came, there can be no doubt of their usefulness; they did the duty of history and eloquence.

As the Christian religion spread and prevailed, arts and letters were diffused; modified, however, by belief and tradition. The fine arts no longer spoke with a Greek or a Latin tongue; they pleaded the cause of Christ, of mercy, humility, and humanity; and as they addressed a people who had no sympathy with aught that heathen elegance had produced, they prevailed almost universally. It is true that, in some parts of Asia, as well as portions of Europe, the new aim which Christianity desired, to give to the arts had to contend with the old aim given by Pagan genius, of which the impulse long continued. For centuries, science and skill, as well as old associations, were all in favour of the gods of Olympus; the religion which those marvellous works embodied was a visible and a sensual one. The days of divinities and oracles were remembered by scenes of festivity and mirth, by processions, and sacrifices, and feasts; and the people were reluctant to relinquish the present enjoyments of the earth for the bright reversion of paradise. Their cry was, "Great is the Diana of the Ephesians!" They could see, but they could not imagine; and were unable to comprehend the nature of that bliss which was not of this world. The divine power of the gospel prevailed, aided by the simple manners and fervent eloquence of the preachers.

For several centuries, however, art and letters had to contend for existence; not with the monks

and hermits, as has been asserted, but with that love of blood and conquest which, like a demon, possessed all the successive hordes of barbarians who issued from the "frozen loins of the north." No doubt the monks and earlier saints looked coldly upon classic writings, as well as upon classic art, because the heathen had their trust in them, and hoped, through the ancient poets, philosophers, painters, and sculptors, to recover their dominion over the minds of mankind. In preaching against Homer, or Plato, or Apelles, they did not scorn their genius; they desired but to teach their flocks that salvation did not reside in their works, and that, if they desired to be happy hereafter, they must turn to the gospel of God from false religion and vain philosophy. With the church, therefore, science and letters found an asylum. Kings and chieftains looked on literature as a thing effeminate, and rejoiced that they could neither read nor write. When abroad, they confined their attention to war and the chase; and on their return, their domestic pleasures were the wine-cup and the legend. From this mental darkness and confusion light and order at last dawned, and came forth; but the light was not that which shone in Greece of old, nor was the order according to the taste of antiquity.

All was changed; new nations, as well as new rulers, were become lords of the earth; the spirit of the north refused to work according to the compass and square of the south, and imagined and created an architecture, sculpture, and painting altogether its own. The temples of Greece and Rome, with all their gods and goddesses, were forgotten; and new temples, distinguished for their picturesque splendour and geometrical unity, were raised, to which painting and sculpture were, as they had been in Egypt, auxiliary and subordinate. This is the architecture designated Gothic—which the ingenuity of the learned has traced to the buildings of Greece—which the imaginations of the poetic have discovered in the wattled wigwags of our ancestors—but which may safely be pronounced new and original, since all its forms, combinations, and ornaments belong to itself alone. How the simple beauty of the Greek architecture could grow into the melancholy magnificence of the Gothic; how it could change its character, upset all its combinations; how the temple of Saturn could become the cathedral of Salisbury, I must desire those to explain who are ingenious in discovering resemblances which do not exist, and who can see the finished statue in the unquarried block, and a noble poem in a printer's type-box!

Those who are acquainted with the physiognomy of nations, imagine that they perceive in the new architecture the peculiar mind and fancy of the Gothic tribes. The gay, the mercurial Greeks would have thought of the descent of their own Ulysses into the shades, had they entered a Gothic cathedral. The twilight aisles, the cold, fantastic ribbings and knottings of the arches overhead, the niches and recesses filled with stern saints, afflicted madonnas, and with recumbent figures, looking the corpses they imitated, and the lettered gravestones under their feet, would have put a Spartan soldier to flight. The Gothic warrior, on the other hand, felt a not unpleasant melancholy in his mind as he passed the threshold. The haunted woods and darksome vales of the north had prepared him for kindred glooms; the banner and the scutcheon told him of his predecessors in martial glory; the windows shed "a dim religious light," which suited the hue of his thoughts; the voice of the preacher, sounding through the aisles, united with the graves of the dead to make him look upward, and he left the house of God with a solemn step and a saddened spirit, which he could not have known had he visited a Grecian temple.

The early architecture of this rude people was useful and intelligible, but not elegant. It was partly wood and partly stone; nay, one of our earliest Saxon churches was of wicker work. The workmanship was coarse, the design heavy; nor did the painting or the sculpture which it contained atone for such defects. Saints and apostles carved with a hatchet; legends delineated with a mop rather than a brush; postures straight, stiff, and formal; lineaments rudely indicated; expression harsh and savage; all told, as plain as with a tongue, that the science and skill displayed in the Greek and Roman works were departed from the earth, and that man had to begin his studies anew. As the Christian religion spread and grew strong, the fine arts expanded with it; science was applied to the humble fabrics in which the cross of Christ was first set up; the simple form of the cross on which the churches were founded was embellished with taste and skill; geometry came to the aid of the architect, and aided him in forming those elegant and remarkable combinations of beauty and strength, which are the wonder of all who are not blinded with classic glory. The sculptor and the painter also exerted themselves; rigidity of form relaxed into nature; a saint-like mildness of sentiment succeeded to savage expression; something of heaven was stamped on the face; a rude divinity of meaning gave an interest

to the groups, and robes, which formerly depended like icicles, began to grow soft and flexible, and an air of ease, and a capability to think, was impressed on all they touched. This was the work of centuries, and did not arise from the influence of one master-mind; it was the result of growing knowledge, and of a taste for the elegant; modified, however, by the Christian religion, which was interpreted to forbid the seeking for information in heathen sources, and the drinking at other well-springs than those of the church.

Though many pictures, pronounced by the monks noble, and statues of saints, reckoned by the friars divine, were produced during the early ages of the church, we must regard Cimabue as the Chaucer of art; for with him came a maturer science, and above all poetry. He found art in much the same condition as the sculptors of Greece received it from those of Egypt; and he purified and elevated it, and rendered it more worthy of that divine religion with which it was associated. What the fine arts had been doing during the twelve hundred years which intervened between the days of the apostles and those of Cimabue, may be read in the history of the world. One horde of barbarian conquerors succeeded another; war followed war; now a barefooted monk sat on the throne of the Cæsars; then a barbarian from the Danube or the Wolga, and both exercised a power hostile to the development of such genius as delights in noble or lovely creations. That this first of Christian painters was inspired by the consummate models of heathen art, cannot be disproved, though it may be doubted. The superstitious zeal of the image-breakers of the preceding centuries had been directed against those magnificent reliques of Grecian genius; they destroyed in their wrath all that the Huns and Vandals had spared, and little was left save what lay buried in the ruins of towns and temples, to be dug up in a happier age. Neither could the intercourse which still subsisted between Rome and the capital of the East be of advantage to his studies; their alliance was shaken by difference of interest, and imbibed by religious disputes; and, moreover, we are yet to learn that Constantinople had arts to boast of worthy of being communicated. Cimabue had to rely on his own inspiration, and his works were the wonder of his own as well as aftertimes. He painted a life-size picture of the Virgin Mary with so much success, for Florence, his native place, that the citizens treated him with honours almost divine; his work was borne in solemn procession to the church, and the happy day was celebrated by a public feast. He

painted many scriptural and legendary pictures, and though his style was a little harsh, and his drawing inaccurate, his paintings were long the study of the student and the wonder of the devotee.

Cimabue was of a noble family: but true genius is of no rank or caste: his pupil and successor, Giotto, was a shepherd; he left the sheep-crook for the pencil, and soon excelled in beauty of design and in natural ease and grace. He at first formed pictures with labels issuing from the mouths of the chief characters telling their name and history; he soon dispensed with this easy system of expression and produced what he desired by means of shape and sentiment; nor did he confine himself to church legends, the imaginary labours of questionable saints, or to images of the virgin and the apostles; to him we owe the portrait of that heir of immortality, Dante; he likewise painted Brunetti, and others distinguished for literature and eloquence. The pope perceived the worth of one who excelled in devout delineations; he employed him in embellishing St Peter's, and honoured as well as rewarded him. This was Benedict the Ninth: the example of his Holiness was followed by succeeding pontiffs, and the painter and the sculptor became necessary servants in the household of one who had the ability to reward them on earth, and the power, real or imaginary, to smooth their ascent to heaven. The churches of Italy imitated, perhaps envied, that of Rome; he was summoned to Naples, Milan, Lucca, Areggio; nay, his native city, Florence, perceived the genius of its humble son, and his pictures on the walls and ceilings of her principal churches remained for centuries to attest that he had sought in nature for the expression and action of his figures, and sought successfully.

It is remarkable that sculpture began at the same time to feel the inspiration which lifted painting into the region of poetry and beauty. The change was felt as well as perceived; statues, and groups, and processions had hitherto been regarded as little better than carvings of flowers and fruits, and things natural or grotesque, whose chief object was to enrich the plainness of the architecture, and give light and shade, rather than sentiment, to the walls. The moment that poetry and science brought order and grace among them, they began to be looked at for what they expressed rather than for what they represented. Yet the unity required in Gothic architecture was not violated; the new attractions bestowed on the sculpture were still in keeping with the original conception; architecture remained lord of the ascendant, and painting and

sculpture were his auxiliaries; necessary at first, and still more so now that genius had opened their lips and enabled them to speak to the world. Those who desire the true Gothic union of painting, sculpture, and architecture, should have Westminster abbey, during its centuries of catholic glory, placed before them: no organ in those days interrupted the eye in viewing the sublime harmony of the structure: the apostle stood austere in his niche; the virgin looked meekly and benignly from the wall; the mitred abbot and the sandalled saint lay carved in alabaster above the spot where their bodies were buried; while our kings and warriors seemed to lie in slumber, rather than in stone, beneath their carved screens and within their dim recesses. All was solemn, and all was holy. Look at Westminster abbey now: modern sculpture has started out of keeping with the architecture, nay, has openly proclaimed war against it. Figures and groups come audaciously into the body of the building; they no longer confine themselves to niches and recesses; nor is this all, some of the statues are engaged in works not at all devout, and the architecture of their pedestals and accompaniments is of all orders, simple or composite, save the order that would correspond with the structure which contains them.

In the period of which we write the unity which we admire was still unviolated; this perhaps arose in some measure from the artists of those days being painters, sculptors, and architects; they maintained the subordination due to each, and left to latter artists the ungentle task of disuniting them and destroying the true harmony of a Gothic building. Of the progress made by sculpture in other lands it will be enough to say, that it retained all its original simplicity amid the new beauties with which taste and genius adorned it, and that it continued in the service of the church, giving form and substance to legends and miracles, and sentiment to saints, male and female. The progress which it made in our own island demands our notice in a twofold way, for we shall see in it the sculpture of Italy and France, and, moreover, trace the first footsteps of our native sculptors, and observe how far they obeyed an imported spirit or followed an impulse all their own. Those who have studied the rise and progress of the fine arts in Britain, cannot fail to have observed that little knowledge could have been derived from the Romans, because, in the first place, the memory of their practice had perished amid the ferocious wars which the Saxons and Danes waged in the land; and, in the second place, that the examples which they left behind them were too rude and

unfished to inspire any one. Bits of Roman statues, fragments of bas-reliefs, and heads of figures, have been dug up, and placed in the antiquarian sanctuary; they are one and all unworthy of being classed as works of art, and countenance the surmise that they were the labours of the soldiers rather than of Roman artists. Some of their mosaics, indeed, are of a poorer design; they have however been imitated from Greek statues: they generally represent Bacchus or Orpheus playing on the lyre, such as may be seen on old cameos and ancient sarcophagi. The sculpture which succeeded was of another kind and character.

It would be unsafe to pronounce our early sculpture excellent on the authority of Speed. "King Cadwollo," says the historian, "being buried in St Martin's church, near Ludgate, his image, great and terrible, triumphantly riding on horseback, artificially cast in brass, was placed at the western gate of the city, to the further fear and terror of the Saxons." An image so barbarous as to scare barbarians must have resembled the Gog and Magog ogres at present in Guildhall, which excite our disgust as well as wonder. "If the statue was terrible," observes Flaxman, "as well as great, that characteristic was the consequence of its barbarous workmanship; for in the year 677, when Cadwollo died, the Goths, Franks, and Lombards, and other uncivilized nations, had nearly exterminated the liberal arts in Europe." In truth, little dependence can be placed on such testimony; all ideas concerning the excellence of art are relative. Evelyn, one of the most accomplished men of his time, speaks of the matchless paintings of Verrio, at Windsor; he failed to perceive that they were all grouping, and form, and colour, without feeling, or sentiment, or originality. It is otherwise with the earliest sculptures of British growth which time has spared to us; they are essentially Gothic; they represent passages of Scripture, both of the Old and New Testament; their form, their grouping, their character, have nothing of Greece or of Rome; nor can it be perceived, as surmised, that something of the presence of Arabian or Saracenic art may be detected.

The cathedral of Wells was built by bishop Joceline, who died in the year 1242. "The west front of this church," says Flaxman, who wrote from personal observation as well as genius, "equally testifies the piety and comprehension of the bishop's mind. The sculpture presents the noblest, most useful, and interesting subjects possible to be chosen. On the south side, above the west door, are alto-relievos of the Creation, in its different parts, together with

the Deluge, and important acts of the patriarchs. Companions to these, on the north side, are alto-relievos of the principal circumstances in the life of our Saviour. Above these are two rows of statues, larger than nature, in niches, of kings, queens, and nobles, patrons of the church, saints, bishops, and other religious persons, from its first foundation to the reign of Henry the Third. Near the pediment is our Saviour come to judgment, attended by angels, and the twelve apostles. The upper arches on each side, along the whole of the west front, and continued in the north and south ends, are occupied by figures rising from their graves, strongly expressing the hope, fear, astonishment, stupefaction, or despair, inspired by the presence of the Lord and Judge of the world in that awful moment."

The execution of this work is inferior to the conception; nor is it at all equal to the workmanship of our own times, though few of our sculptors would venture on a subject so bold and poetic. There were then, it has been surmised, no schools of drawing, no teachers of anatomy, and no lecturers on the fine arts; a few learned monks only were acquainted with geometry and mechanics; and the application of science to the figure and motions of man was a matter unknown. In consequence the sculpture on Wells cathedral is ill drawn, and defective in true principle, and carved too in a style rude and severe; yet there is a beautiful simplicity, an irresistible sentiment, and sometimes a grace excelling more modern productions. Nor should it be forgotten that these works were finished even before the birth of Cimabue, and were in progress during the lifetime of Pisano, the restorer of sculpture in Italy; even in the conception priority may be claimed; there are compositions by Giotto, and later artists, representing the creation of Eve, but that sculptured in the cathedral of Wells is not only the oldest, but is not inferior to the others, though one of them bears the name of Michael Angelo. The name of the artist is unknown; but it has been observed by one who was seldom mistaken, that there is some reason for claiming him as an Englishman, since his work is wholly different in character from the tombs of Edward the Confessor, and Henry the Third, which were by Italian sculptors.

The long reign of Henry the Third was favourable to art: the castles of our nobles were only remarkable for their heavy grandeur and their massive strength, and for being the residence of turbulent and illiterate owners; it was otherwise with our abbey-steads and cathedrals; the owners were wedded to heaven, or rather to their

order, and expended the vast revenue raised from the love or the fears of mankind, in the embellishment of the church. It is true that travelling scholars, wandering bards, and other strangers, were entertained hospitably, but the surplus, which our married clergy bestow upon their wives and children, was laid out by the clergy of the Romish church on illuminated missals, splendid copies of the evangelists, statues of saints and founders of their order, and on pictures by the most inspired masters, in which the glory of religion was maintained, and the taste and wealth of the proprietors manifested. During those days grants were made of oaks from the royal forests for the manufacture of saints and apostles; quarries were opened for the construction of sacred edifices; artists were allured from foreign parts, and encouragement extended to those at home, and the cathedrals of York and Gloucester, and others scarcely inferior, were erected, forming the wonder of their age as well as of our own.

The outlay of genius as well as labour in our Gothic edifices is truly wonderful: the geometrical combinations and unity of the whole are scarcely less remarkable than the ornamental detail and sculptural enrichments of every part which court the eye. With what skill processions of saints and labours of the apostles are made to work harmoniously in with the starting of arches, or the gatherings of bands; with how much taste an angel or a devil—for the church employed both—supports the fantastic ribs of the arched aisles: how gracefully a madonna performs her duty, by sustaining the weight of some important portion of the church, while into the hollow, or upon the swelling members of cornices or bands, histories and miracles are delineated, often with great force and elegance. In one of the screen cornices in Westminster abbey, we have a whole royal history carved; there is a royal birth, a coronation, a royal judgment-seat, a royal festival, a royal wedding, a royal voyage, a royal visit to a cathedral, and, finally, a royal deathbed. All this is pronounced barbarous by classic scholars and others who see little merit in aught new, and who deem it a nobler thing to correct a passage in Pindar or Plutarch than create a *Paradise Lost*, or a *Macbeth*. The love of classic architecture is not natural, but inoculated, and must sink beneath the taste of the public which perceives genius akin to its own in the geometrical combinations and historic and legendary embellishments of the Gothic architecture.

The impulse given to painting by Cimabue and Giotto was felt all over Christendom; archi-

itecture nevertheless detained it long in bondage as an auxiliary, nor was it till the fifteenth century that it asserted its superiority and independence. The frescoes of Masaccio, the works of Mantegna, and the genius of Luca Signorelli of Cortona, united the dawn of art with its fuller radiance—the days of Giotto with those of da Vinci. The merits of Signorelli were of a high order; he contemplated his subjects with a discriminating eye; he determined what was accidental, and what was essential and fixed; he balanced light and shade, and foreshortened with a happy boldness which Michael Angelo did not disdain to imitate. A brighter star now arose: “Leonardo da Vinci,” says the enthusiastic Fuseli, “broke forth with a splendour which surpassed former excellence: made up of all the elements that constitute the essence of genius, favoured by education and circumstances, all ear, all eye, all grasp; painter, poet, sculptor, anatomist, architect, engineer, chemist, machinist, musician, man of science, and sometimes empiric, he laid hold of every beauty in the enchanted circle, but without exclusive attachment to one, dismissed in her turn each. To a capacity which at once penetrated the principle and real aim of the art, he joined an inequality of fancy, that at one moment lent him wings for the pursuit of beauty, and the next flung him on the ground to crawl after deformity: we owe him chiaroscuro with all its magic; we owe him caricature with all its incongruities.” This great painter was distinguished in his best works by a calm, a solemn grandeur of soul which nothing has ever surpassed; his *Last Supper* has a tranquil sublimity, a pathetic grace diffused over it, which contrasts strangely with the whirlwind charge of his horsemen in the celebrated cartoon for Florence.

A graver, a severer dignity of execution has been claimed for Bartolomeo della Porta; his style was pure; the subjects which he selected were chiefly serious; his draped figures have great simplicity; his naked figures show his acquaintance with anatomy and the antique; he foreshortened with equal boldness and accuracy, and used his drapery as subordinate to the body which it exhibited rather than concealed. He is considered the true master of Raphael; nay, critics have intimated that he had influence on what Fuseli calls the mighty style of Michael Angelo Buonarroti.

Of Michael Angelo much has been written and said: to the imaginative he appears the mightiest of all the children of art; to the cold and the reasoning he seems wild and extravagant; but all agree that his genius was various and of the

highest order. His statue of Moses belongs to a mightier race of men than the present mortals who inhabit the earth; there is a morose, some call it savage, grandeur about it; the soul of the beholder feels elevated by contemplating it; Scripture is realized. His fabric of St Peter, deficient though it seems in unity, is stamped with a sublimity seldom seen in architecture: and his pictures reject all supplemental ornament, all charms of oil colour, and appeal to the heart and imagination with a force which the coldest acknowledge. The epic serenity of his works is indeed injured by occasional extravagance of posture, and the dignity of his forms perplexed by an ostentatious and swelling anatomy, yet all who are intimate with the loftiness and variety of his creations will hardly suspect that Fuseli said more than was merited in the character which he drew. "Sublimity of conception, grandeur of form, and breadth of manner, are the elements of Michael Angelo's style. By these principles he selected or rejected the objects of imitation. As painter, as sculptor, as architect, he attempted, and, above any other man, succeeded to unite magnificence of plan, and endless variety of subordinate parts, with the utmost simplicity and breadth. His line is uniformly grand; character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur; a beggar rose from his hand the patriarch of poverty; the hump of his dwarf is impressed with dignity; his women are moulds of generation; his infants teem with the man; his men are a race of giants. To give the appearance of perfect ease to the most perplexing difficulty was the exclusive power of Michael Angelo: he is the inventor of epic painting, in that sublime circle of the Sistine chapel, which exhibits the origin, the progress, and the final dispensations of theocracy. He has personified motion in the groups of the cartoon of Pisa; imbodied sentiment in the monuments of St Lorenzo; unravelled the features of meditation in the prophets and sibyls of the Sistine chapel; and in the Last Judgment, with every attitude that varies the human body, traced the master-trait of every passion that sways the human heart."

In this high-wrought character the faults as well as the excellencies of the works of Michael Angelo are indicated, though not intentionally; he generally did too much; action with him becomes painful; he is seldom easy, and simple, and always too picturesque. The milder but equally lofty genius of Raphael gladdened the world at the same time with the planet Michael;

he has been termed the father of dramatic painting, and the artist of humanity; he merits higher praise. In delineations of angelic emotion and heavenly grandeur, in calm dignity, "in looks commercing with the skies," he has been equalled by none. The muscular animation of Angelo is mistaken for mental vigour; the tranquil thought and meditative postures of Raphael are pronounced deficient in loftiness. The latter imitated the composure of the gods, and knowing that the religion of Christ was of the soul and not of the body, he stamped a celestial spirit on all his works; the former has more of the "double double, toil and trouble" of human life in his creations; his angels seem inclined to perform miracles by strength of arm, and he abounds so much in violence that action becomes painful. "Michael Angelo," says Fuseli, "came to nature, nature came to Raphael; he transmitted her features like a lucid glass unstained, unmodified. We stand with awe before Michael, and tremble at the height to which he elevates us—we embrace Raphael and follow him wherever he leads us. Energy, with propriety of character and modest grace, poise his line and determine his correctness. Perfect human beauty he has not represented; no face of Raphael's is perfectly beautiful, no figure of his in the abstract possesses the proportions which could raise it to a standard of imitation; form to him was only a vehicle of character or of pathos, and to these he adapted it in a mode and with a truth which leaves all attempts at emendation hopeless. His invention connects the utmost stretch of possibility with the utmost plausible degree of probability, in a manner that equally surprises our fancy, persuades our judgment, and affects our heart."

In composition, Raphael is equalled by few, and excelled by none; the chief circumstance, the leading feature of the picture is not only visible at the first glance, but it is stamped so effectually on the performance that the sentiment which it awakens pervades every group and all accessory figures. He introduces no forms because the canvass and not his story requires them; the eye is not perplexed by secondaries pushing themselves into notice like principals. All is harmony, whether composition, character, or colouring; dramatic propriety is every where observed, and no epic poem can have greater unity or greater breadth; all this is combined with a wondrous simplicity—a simplicity scarcely of this earth, it is so lovely and so holy.

Some, nay many, of the companions and successors of these illustrious artists were scarcely inferior in beauty of form or grace of expression,

while in harmony, Correggio is admitted to have excelled them. "The harmony of Correggio," it has been observed, "though assisted by exquisite hues, was entirely independent of colour; his great organ was *chiaroscuro* in its most extensive sense; compared with the expanse in which he floats, the effects of da Vinci are little more than the dying ray of evening, and the concentrated flash of Giorgione, discordant abruptness." Titian was another of those gifted masters; he excelled in delineations of voluptuous beauty, and in splendour of colour; but in his hands art lost something of its severe grandeur. Tintoretto, too free to be correct, and too daring to be chaste; followed in the same path, and produced works sometimes rising to the sublime, more frequently descending to the timid. The almost supernatural brilliancy of colour which distinguished the Venetian branch of Italian art has been instanced by all painters, particularly those who dealt in duller materials, as a falling off from the severe dignity of the true historic; this is perhaps true, for the colours may be too celestial for figures of mere flesh and blood; but it is true only in those works where conception and character are subordinate to the colour. Had the genius of Titian or Tintoretto been of the same order as that of Raphael, their sentiment would have rivalled their heavenly hues; there is a want of unity and propriety in their performances on that account alone.

While painting was achieving a fame rivaling that in Greece of old, sculpture was advancing, though not with equal success and fortune. Something of this tardiness of growth must be attributed to the climate as well as to the peculiar character of the Gothic tribes. Our northern lands are cold and moist, compared to the sunnier regions whence sculpture came; we are clad in close thick dresses, and unaccustomed to the sight of naked beauty, are startled at the rude figures which filled the isles and continent of Greece. Our taste too inclines more to the picturesque; splendid colours and action, which compared to the repose of ancient statuary, may be regarded as extravagant, are more acceptable than what is simple and staid. Religion, too, called for greater decorum of design; our madonnas were not permitted to bare their voluptuous bosoms; and our male saints, who exhibited their bodies, were those only who had grown skeletons by fasting and vigil, or who were tied to the stake, to be stoned, or flogged, or burnt. It is true that art escaped from this penitential restraint, and displayed all that was beautiful or attractive in form or colour; for centuries, nevertheless, the soberer influence pre-

vailed, and figures male and female were manufactured, the severity of whose looks and forms were sufficiently forbidding and repulsive.

The sculptors who first escaped from this ascetic style into something like nature and poetry were Nicolas Pisano and his son John; they executed some magnificent marble pulpits, adorned with basso relievos and statues, in Pisa and Sienna. They studied the antique sculptures of the Campo Santo; yet there is more of Gothic grandeur than of Greek simplicity in their productions; the positions are elegant and the draperies natural. Donatello, the Florentine, followed; he was a worker in bronze as well as marble; in the cathedral of Florence there is an alto-relief of two singing boys of extraordinary beauty in sentiment and drawing. Also a bronze statue of a youth in the gallery of Florence, so delicately proportioned and so perfectly natural as to be surpassed only by the best works of antiquity; his statue of St George united such simplicity of conception with such living sentiment, that Michael Angelo, after beholding it in wonder for some minutes, suddenly exclaimed, "march!" Ghiberti succeeded, and more than rivalled him in the celebrated bronze gates of the Baptistry of St John, which Angelo declared were worthy of being gates to paradise. The art reached its height in the hands of him who proudly wrote himself "Michael Angelo, poet, painter, sculptor, and architect." In all his works there is a loftiness of conception which shows that sublimity and grandeur were his natural elements; his delight was to be daring; he invaded the sanctity of heaven for subjects, and he penetrated to the depths of hell: the chief actors in his wondrous scenes are gods and demons, and souls of men condemned or saved: with man in his common and household mood he refused to grapple: he touched indeed on female beauty, but it was loveliness connected with the sublimities of religion which he contemplated: he scorned little things, and it may be said of him as it was of Milton, that he could hew a colossus out of a rock, but could not carve a head out of a cherry stone. Yet it must be acknowledged that Michael Angelo sacrificed, oftener than was required, true simplicity to picturesque grandeur: his best groups and his finest figures want the compact elegance and severe truth of Grecian sculpture; it is true that he has left specimens in his *Lorenzo di Medici*, and *Virgin and Child*, which may be compared with aught the ancient world produced, but his common fault is excess of imagination, of conception flying too high a flight, and of action forced into extravagance. His desire of uniting

in one vast harmony the three arts in which he excelled, probably injured his fame as a sculptor: to create groups and figures which instead of being lost in the breadth and magnificence of his architecture should stand out not second but first, was the task which he assigned to himself, and this forced him upon the gigantic and the picturesque more than it is likely he wished. His merits may be summed up by the attestation of Flaxman, who studied his works for years in the heart of Rome. "In the Capella Sistini the sublimity of subjects and characters, the several patriarchal groups, of incomparable interest and beauty, all original, and unlike any production of antiquity, with that wonderful altar-piece of the Last Judgment, form, together, a labour that seems scarcely the work of man, and stands without a rival in ancient or modern art."

Whilst these wonders were achieving by painting and sculpture, architecture was not neglected. Many noble buildings were erected in various parts of Europe, in which the simplicity and beauty of Grecian architecture were supposed to be revived. Yet this was rather an application of the Grecian orders to a composite style of building, than an express revival of the old. The Gothic spirit prevailed on the earth; something picturesque and lofty was required; and as this could not be obtained by one line of columns, two or three were employed, and structures rose into the air in which the Doric supported the Ionic, and the Ionic the Corinthian, till the clouds were scaled, and it was believed and asserted that a triumph had been obtained for Christian churches over the heathen temples. This triumph was, however, achieved at the expense of unity, simplicity, and propriety. The principles of the Gothic architecture allow vast altitude; nor are the proportions lost by expansion; and, what is equally important, the materials out of which all this is achieved still continue obedient to the hand of man. Not so the Grecian architecture. To elevate a temple, according to the true principles of ancient art, requires, with an increase of height in the columns, an augmentation of size in the stones; and before the portico can obtain an elevation of an hundred feet, the materials have become nearly too heavy for human handling. All this was perceived by the Christian architects; and they imagined they had vanquished the difficulty when they placed one row of columns above another. As far as picturesque splendour is useful, they succeeded; but they succeeded at the expense of propriety and truth. The porticos and colonnades of the Grecian temples were useful as well as beautiful; for in Greece they

made nothing without a meaning. Men found shelter there from sunshine or from shower; and, that their time might not be wasted, historical sculptures extended all around, reminding them of the deeds of heroes and the acts of the gods. But under the second row of columns, and within the upper porticos, of the new style of architecture, birds and angels alone could find shelter. Look at the front of Whitehall and the porticos of St Paul's, and say, of what use, save to be looked at, or wondered at, are those columns and friezes. The world abounds with such examples of modern invention. They are beautiful, it is true; and it may be a question whether such elevations could have been achieved by Grecian principles and British materials; for blocks of stone, of seventy or eighty tons' weight, are not produced in every quarry, and cannot be raised a hundred feet high in the air by common machines. Inigo Jones, in his Corinthian portico of the old St Paul's, had to wait long for, and at last obtained with difficulty, a block, of some thirty tons' weight, to cover the opening between the central columns. That architects persevere in this composite or hermaphrodite style of art, is to be accounted for by their proper admiration of the temples of Greece and Italy. They seek to compound the matter with the Gothic predilections of the present Christian nations of the earth; and the result is something which men admire and find serviceable, but the propriety and meaning of which it would be dangerous to discuss.

A great and a sudden change was now at hand. All historians and lovers of art unite in saying that painting, sculpture, and architecture, under the fostering care of the Romish church, had nearly reached perfection, when the Reformation destroyed at once the unity of the Christian religion, and arrested art in its upward career. How this came to pass, need not be described minutely. The discovery of printing diffused knowledge; men were enabled to see with their own eyes; and as Scripture was written so that all might read, the light of the gospel suddenly burst over the land. Wise and scrupulous men began to compare the simplicity of the primitive church with the splendour of that of Rome. They could not shut their eyes to the difference between the Saviour of the world riding into Jerusalem on an ass, and his infallible majesty, the pope, seated amid the magnificence of modern Rome, summoning princes to his presence, exacting tribute from all nations, and holding in one hand the key of heaven, and in the other that of hell. The use of images, too, and pictures, had been sadly abused. At first,

as has been intimated, such auxiliaries were necessary to explain the word of God to barbarous nations; but when printing had opened the sacred volume to all eyes, the charm of painting and sculpture, as applicable to religion, was dissolved. The New Testament revealed all, and that, too, in a way infinitely more direct and simple than through the medium of art. It was discovered also that apocryphal miracles and saints had usurped the places which true saints and real miracles merited. The light of Thomas à-Becket of England, for instance, obscured that of Christ and the Virgin; nor were there wanting votaries, at once so zealous and so ignorant, as to kneel to insensible pictures and images, in preference to supplicating the Most High.

All this, no doubt, time and knowledge would have cured; but the catastrophe was hastened by the fiery determination of the first reformers concerning the abolition of indulgences and other corruptions, and the resolution of an infallible priest to permit none of his actions to be questioned. Art suffered seriously by the contest; the magnificence of religion suffered an immediate eclipse; the reformers refused the aid of painting and sculpture in interpreting the Scriptures; they desired to have them as Christ and the apostles wrote or uttered them, without gloss or comment; they preached down the legions of saints, male and female; they looked cold on the pictures and statues of the apostles, for they knew they were imaginary; they saw the image of the Blessed Virgin, and thought but of the follies committed at her shrine: in short, they broke and burned all works of art found in churches, as superstitious, and called all who countenanced them idolaters. This was good for salvation, and bad for art. The noblest works were those made for the church; painters and sculptors wrought, under a twofold sort of inspiration, in the cause of Rome; the pope held the honours of earth in one hand, and the keys of paradise in the other, and he showered the first, and promised the second, to all who excelled in embodying the current beliefs and holy legends in colours or in marble. The artists of the reformed nations had no such stimulants; they had no assurance that honours on earth and happiness in heaven awaited their labours; they were compelled—with manifest reluctance—to turn from forms purified by celestial intercourse, angels, archangels, and the souls of just men made perfect, to forms gross and corporeal—to the fallible creatures of the earth; and from man, with his worldly passions and pursuits, form a new sort of art, worthy of finding a place in the halls and houses of the gentry and the nobles.

The painter and the sculptor were no longer called upon to unite with the architect in forming a church such as that of St Peter's or of Westminster abbey; the poetical portion of art was excluded—for a time at least—from the company of things holy; the godlike air, and the rapt, inspired look, departed from pictures and statues; for the blessed angels, we had squires and nobles, with square-toed boots and padded jackets; for virgins and saints, we had court ladies, patched and jewelled; and for apostles, we received mayors of corporations, in full-bottomed wigs, with maces borne before them. This was turning from imagination mingled with nature, to nature without imagination,—no wonder that

“Folly clapp'd her hands and wisdom star'd.”

This is spoken only of art in the reformed nations. But the impulse extended to Catholic countries; and Rome, from that hour, fell off in her glory, nor has the genius of any of her sons been able to restore the tiara to her discredited head.

In Britain the change was sudden, and, perhaps, injurious. The true spirit of painting and sculpture, animated by poetry, and purified by science, had more than opened its eyes, when the civil wars of the land crushed the national genius, and threw us centuries back in the scale of civilisation. Those wounds were healed by Henry VII.; commerce spread her sails; discoverers went in quest of unknown lands; and the genius of art exhibited in the Chapel of the King such beauty of combination, simplicity of conception, and richness of emblazoning, as had not hitherto been equalled in the island. “It has been said,” observes Flaxman, “that the number of statues within and without this chapel amounted to three thousand. Perhaps many of these have been destroyed, and in that number every half figure or animal may have been reckoned, but certainly, even at this day, the number is very great; and it is another marvellous example of the astonishing estimation and employment of sculpture in this kingdom before the Reformation. Torrigiano seems to have been employed on the tomb only, and had no concern with the building or the statues with which it is embellished. The structure appears to have been finished, or nearly so, before Torrigiano began the tomb; and there is reason to think that he did not stay in this country more than six years, which time would be nearly, if not quite, taken up in the execution of the tomb, and some other statues about it, now destroyed, together with the rich pedestal and enclosure.

From the names of several English painters, sculptors, founders, and masons mentioned in the documents, who were not concerned in Torrigiano's engagement, we may presume the chapel and its sculptures were native productions. The figures are superior to those of the tomb in natural simplicity and grandeur of character. We must now take a long farewell of such noble and magnificent works of art, in raising which the intention of our ancestors was to add solemnity to religious worship—to impress on the mind those virtues which adorn and exalt humanity."

This British sunrise of art was obscured by the reformation. In the year 1538, images which had been worshipped were commanded to be destroyed. This injunction was afterwards extended to all images whatsoever; and as pictures as well as figures were included, the destruction was immense. The paintings were torn down, cast into heaps, and burned; the statues were thrown out of their niches, and broken to pieces; those which were fixed to the walls had their heads struck off, as well as their hands; and this happened to saints, apostles, warriors, and kings. Many noble sculptures perished. In repairing one of our cathedrals lately, dozens of those heads were found, some of them eminently beautiful, excelling both in form and sentiment. To destroy the sculptures of a Gothic building, is to pick the jewels out of a royal crown; they are in imagination all compact with the architecture, and cannot be removed without destroying that fine harmony and beautiful variety for which those structures are remarkable. "The commands," says Flaxman, "for destroying sacred painting and sculpture, effectually prevented the artist from suffering his mind to rise in the contemplation or execution of any sublime effort, as he dreaded a prison or the stake, and reduced him in future to the miserable ministry of monstrous fashions, or drudging in the lowest mechanism of his profession. This unfortunate check to our national ability for liberal art occurred at a time which offered the most fortunate and extraordinary assistance to its progress. The lately-discovered art of printing began to enlighten the European hemisphere with the beams of knowledge in all directions. Copies of the Bible were generally dispersed; the philosophy of Plato and Aristotle were understood, and well illustrated; mathematics were successfully studied, so was anatomy; linear perspective had been, in a great measure, perfected, by Paul Uccello, the Florentine, some time before. These advantages did much towards the formation of Raphael, Michael Angelo,

Titian, da Vinci, and Correggio, in common with the great scientific and literary luminaries of the same period, among whom we may boast our Bacon, Shakspeare, Spenser, and afterwards John Milton. But the genius of fanaticism and destruction arrested our progress. The iconoclastic spirit continued, more or less mitigated, till its great explosion during the civil wars." The crusade preached in England against painting and sculpture extended only to works found in the churches; in Scotland, the popular fury was directed, for selfish purposes, against the structures, in which all images were enshrined. The magnificent cathedrals and abbeys were passed under the remorseless harrow of Knox and his companions; that of Glasgow alone escaped, like the righteous servant from the destruction of Job's house, to tell of the ruin of the rest. That many fine paintings perished, is not likely; but illuminated books and manuscripts, with thousands of statues, were burned and broken; and all, too, with the idea of doing a deed serviceable to true religion, and welcome to God. The religion for whose sake all this was done has been restored to its rank and influence; but the noble edifices, who will rebuild them!

Painting, sculpture, and architecture, seem to have more of the sensitive plant in them than has fallen to the lot of poetry; for while the former were idle through fear, the latter, in the strains of Shakspeare and Spenser, had asserted the right of the muse of Britain to stand on the same elevation with the heathen muses of Greece and Italy. Protestants perhaps had a scruple of conscience in works of painting and sculpture. We were willing to accept the assistance of other countries in a manufacture which had ceased at home. France was ready to supply us then, as now, with whatever we desired of the neat, the polished, and the affected. Spain might have furnished us with examples of a gloomy splendour and a sullen beauty. From Italy we refused to receive anything, for we dreaded the mark of the beast, and the pollution of the scarlet; but from Holland—dear, dull, protestant Holland—we imported works of art, and artists too, with right good-will. To the market of the United Provinces we went with a wary eye; we had the love of our immortal souls much at heart, and traded cautiously. Yet much caution seems not to have been required; for who would dread to find an apocryphal apostle in a Dutch burgomaster, a madonna in a seven-petticoated dame of Amsterdam, or a St. Stephen or a St. Lawrence in the drinking and drabbing scenes of Teniers and Ostade. From

Holland we, as good protestants, purchased pictures and borrowed artists; and something of the literal spirit of that plodding and unpoetic people is still visible in our works.

On the continent, as well as in Britain, painting suffered an eclipse from the Reformation, and the political and moral changes which it wrought. The lofty aspirations of the Romish church had been equalled by the miracles wrought by art; and all that was bright in heaven, or dark in hell, was revealed to the people in pictures, which continue to astonish the world. But the lofty pretensions of the pope,

"Holy at Rome, here antichrist,"

were rebuked by the reformers. Art lowered its tone, too, and exhibited more of earth and less of heaven; processions of princes and peers, by land or water, took place of those of apostles and angels; instead of a madonna seated on a blue cloud nursing the offspring of heaven, we had a queen of France or of Spain seated on velvet, and feeding the heirs of these kingdoms by proxy; for glimpses of paradise, we had interiors of palaces; and for glorious landscapes, with angels ascending and descending, art supplied us with cows grazing in meadows, and with boats fishing in the Zuyder Zee. To many this change was welcome; for minds literal and unpoetic rejoice in scenes which require no exercise of the imagination. To art it was injurious; for it reduced its labours to a better sort of portrait-style, in which a map was given of the land, and a fac-simile taken of its people. It is the duty of art to exercise our memory less than to elevate our minds; for, of itself, what can the noblest statue or the brightest picture tell us? but for Homer and history, who would understand the Laocoon or the Apollo? This is true of the pictures of Rubens, as well as of those of Rembrandt. "The former," says Fuseli, "compounded, from the splendour of Paul's Veronese and the glow of Tintoretto, that mannered magnificence which is the element of his art, and the principle of his school; he first spread that ideal pallet which reduced to its standard the variety of nature; and, once methodized, whilst his mind tuned the method, shortened or superseded individual imitation. Rembrandt was a genius of the first class, in whatever relates not to form. In spite of the most portentous deformity, and without considering the spell of his chiaroscuro, such were his powers of nature, such the grandeur, pathos, or simplicity of his composition, from the most elevated or extensive arrangement to the meanest and most homely, that the best

cultivated eye, the purest sensibility, and the most refined taste dwell on them, equally enthralled. Shakspeare alone excepted, no one combined, with so much transcendent excellence, so many (in all other men unpardonable) faults—and reconciled us to them." Yet lofty as this praise is, the heavenly halo which hovers over the works of Angelo, and Raphael, and Correggio, refuses its full lustre to the productions of Rubens and Rembrandt: art was on its descent.

Petronius said bitterly it was easier to meet with a god than a man in Rome: in London, it was easier to meet with a man than a god. The sublime creations of Greece and of Italy evoked no kindred genius in Britain. In vain pictures by Raphael and statues by Phidias were placed before our eyes; we looked, we applauded, but sought not to embody from our eventful history, and our more than glorious poetry, shapes and scenes worthy of the national genius. The terrors of popery seem to have paralyzed us; native art was all but extinguished by the change of religion; our efforts were faint and feeble. Jamesone in the north, and Cooper, and Walker, and others, in the south, reminded us, by miniatures and life-size portraits, that art breathed at least, if it could not move. Nor can it be said that the presence and example of the unrivalled Vandyke had a happy influence. How noble, how heroic, and how graceful his heads still look, when compared with the most fortunate efforts of his British brethren! Nor were there any to contest the pre-eminence with either Lely or Kneller. Thornhill, it is true, imagined that he was the reviver of historic art in England. He united with two foreigners, Verrio and La-Guerre, in filling our mansions and palaces with mobs of gods and goddesses from the heathen mythology. Venus, in nudity, walked a minuet with a countess in a hooped petticoat; Apollo sought to inspire with eloquence a marquis in a full-bottomed wig; and Minerva and Diana walked barefooted on the gravel of St James's Park, between Charles the Second and Lady Castlemain. This was a sort of picturesque painting, which had the outward form without the sentiment, and was equally deficient in natural truth and historic propriety; yet Evelyn speaks of those prodigies of absurdity as miracles of genius, even after he had seen some of the noblest pictures of the great masters of Italy.

A new era was at hand. A succession of great architects, sculptors, and painters arose, who asserted the dignity of British art. The first, and perhaps the ablest, of these was Sir Christopher Wren. Accident called out his genius in all its splendour. The great fire of London

levelled old St Paul's, and under his eye the present magnificent edifice arose into existence. It is not alone what an architect accomplishes that we are bound to admire; we should take into consideration the beauties which he is not permitted to realize—the designs which public opinion or private intrigue prevent him from fulfilling. Sublime in conception, harmonious in combination, and unequalled for geometrical unity though the present edifice is, it is excelled, in all these high properties, by the other model of the great artist still preserved in the archives of the church. The internal arrangement displeased the duke of York, who, desirous of re-establishing popery, wished to have room for the monks. The external elegance offended some of the dignitaries of the church, who desired to see the figure of the cross less embellished; and between them they compelled the architect to adopt a design which he did not wholly approve. Of the worth of what we have lost, we may form some notion from the grandeur of the present structure, which, in lofty elegance and exquisite harmony of parts, excels all works of the kind, ancient or modern. Of the fifty churches of London built by Wren, some are scarcely inferior to St Paul's in beauty and geometrical unity. Vanbrugh had genius of a high order; his works are grand, but irregular; picturesque, but wanting in propriety. He sacrificed too much to situation; in his structures he laboured to raise something in the spirit of the landscape around; and though he succeeded, as may be seen in Blenheim, yet it must be confessed that his works are less pleasing than striking and uncommon. Other skilful architects followed. Some of the dead will live, and some of the living will not die, for their buildings will make their names known to future centuries. It must be confessed, however, that grand structures are not in request, either of a religious or a national kind. Save St Paul's, not a single cathedral has been built in England since the Reformation. The noble old abbeys are the work of Catholic priests, who, married to the church, laid out their wealth on the adornment of their sacred spouse. Nor, since the days of Wren, has a single edifice of a national kind been raised at all worthy of our name. Our palaces—though some have been rebeautified, and that skilfully—are anything but princely; our military and marine structures are for use, it is true, but elegance might have mingled more with the conception; and London, the capital of the first maritime empire in existence, is but a city of brick-stacks, with nothing worthy of outliving it save half-a-dozen churches, the cathedral of St Paul, the bank, Westminster

abbey, and the bridges of London and Waterloo. There is an apathy in the nation for such works; moreover, our architects are divided; our reading and schooling are for the classic, our heart and nature for the Gothic. The latter will likely succeed, and more than an indication of its triumph has of late been made manifest.

In sculpture much has been achieved since the merciless hand of reform was laid upon the saints and madonnas of the Catholic cathedrals. It has, however, wholly separated itself from architecture. It is true that statues still occupy the pediments or recesses of the architect's designs; but these, like the figures of Verrio and La Guerre, are matters essentially picturesque, and have nothing to do with sentiment and feeling. No architect mingles sculpture with the interior of a church or a palace; places are left void, for the genius of the sister art to fill up as opportunities occur; situations for statues are merely indicated, or places for groups or reliefs; while room nigh the altar is left for a picture, to be supplied by the chance charity of some opulent devotee, or of an artist anxious to secure a good light and a large audience for one of his scriptural canvasses, of which no purchaser asked the price. This injures the unity of the architecture, for few sculptors regard—as we may see in Westminster abbey—the harmony of the work around; they desire to bring their own productions strongly forward. Nor is this all; they now and then give secular employments to figures set up in sacred places.

The first of our eminent latter sculptors was Cibber; and the works by which he will be known to posterity are the Madness and Melancholy carved for the asylum at Moorfields. They are boldly and poetically, as well as naturally conceived, and more than approach the designs of the great Italian artists. Cibber sought to revive the antique taste for the presence of sculpture in arbours and gardens, and scattered his fawns and satyrs, and gods and goddesses, among the woods of Chatsworth. But our moist, cold climate is out of harmony with the nude progeny of the sunny lands of Asia or Greece; nor has learning yet induced us to love forms which our reason rejects. Banks, with more than the poetic feeling of Cibber, delighted in classic subjects; his sketches from the works of Homer breathe the true austere spirit of antiquity. They are, however, but little known, with the exception of his statue of Achilles, while his national monuments are too well known, and leave an impression on the public mind unfavourable to his fame. Their chief fault is an utter want of historic propriety; he desired to

throw the mantle of poetry over the ordinary occurrences of war, and produced nothing but mystery and extravagance. Bacon, with a mind of a more literal cast, suited the public taste, and made both fame and fortune. The former has, however, suffered something of an eclipse, though his statues of Johnson and Howard are noble works. Nollekens, notwithstanding the praise of Wordsworth, was essentially a bust sculptor. His mind was mechanical; he had no imagination; he was plodding and laborious, and produced many works—but they were works without feeling or passion. Flaxman had the loftiest genius of all our British sculptors; he was alike simple and sublime; he grappled with the most poetic subjects, and reached their grandeur, as well as their beauty. His designs for the Greek poets have so much of the Greek spirit that they might pass for the sketches of Phidias, while his designs from Scripture reach the height of the great argument of the gospel, and form the only commentary we ever saw in perfect harmony with the original. This is high praise. We must add, by way of abatement, that his execution was not equal to his conception, and that, while in true poetic works he fairly rivalled the works of antiquity, in literal transcripts of life and the times he lived in, he was excelled by sculptors who had not a tithe of his talent. He could show the kernel of things, but he failed in exhibiting the husk.—The living sculptors are numerous, and some are of high talent. Chantrey is natural, graceful, and manly: Baily always elegant and sometimes poetic. Westmacott carves now and then a classic group. The sculpture of Britain has not yet reached, and likely never will reach, the excellence of that of antiquity. With us, it is more a matter of necessity than of genius and feeling; a sculptor is considered as a sort of manufacturer; he has to work according to dying bequests, and to fill a certain space with marble, commemorating particular virtues; he has no liberty in selection of subjects; a soldier perishes in battle, and has a statue; a statesman dies, and has his statue also, and materials are furnished, to ensure a good resemblance, both as respects aspect and costume. This sort of act-of-parliament commission can hardly call a true work of art into existence. It is true, that such men as Egremont, and Devonshire, and Bedford desire to have sculptures of a poetic nature. We speak not of individual cases, but of a general feeling; we have no national taste in such matters. The very mobs of Italy and France respect the presence of works of art; they look on them with admiration and awe, while the crowds of old England scratch, and

crush, and break sculpture without remorse. The first emotion felt on beholding a national statue set up in a public place is, to pull it down, or throw stones at it.

The British school of painting occupies a place between the schools of Italy and Holland. It wants the sublime loftiness of the former, neither is it so low or so literal as the latter; it partakes of the qualities of both, while the spirit of the land shines visibly through it, and establishes its claim to originality. It has great variety, great force, vivid colour, and expression. In lofty emotion, historic dignity, and poetic passion, it is less powerful than in human character, domestic incident, natural elegance, and deep pathos, sharp satire, and a humour rich and deep. Painting has taken few successful flights into the regions of the imaginative, though it has made many attempts; neither has it treated with much dignity and vigour the deeds of daring wrought by Britons, by either sea or land. We have no Shakespeares, Spensers, Miltons, or Scotts in art. The academy, it is true, opens its doors to all, and sets an example by models, and gives advice in lectures, concerning the sublime and the historic. It exports, too, to Rome at stated intervals, certain of the most gifted of its students to feel, with Reynolds, the unreachable elevation of Michael Angelo, or confirm their own notions of what is excellent, by gazing on Raphael, Correggio, and other great masters. Yet, nevertheless, the grand historic style is anything but prosperous. Artists dream of the Vatican, and waken to paint a cow grazing in a meadow, two dogs quarrelling for a bone, a windmill after nature, or a lady patched, plumed, and padded, ready to burst upon some astonished coterie, and fan them into envy with her nodding plumes.

The first great painter of the island is still the most vigorous, most characteristic, and original—we mean Hogarth. Some of his brethren, indeed, deny him the title of painter; though they allow he is a great something, they hesitate to say what. But this is mere pedantry. He is held to be a true painter by all who know what art is; for it is by form, by colour, and by force of expression that he accomplishes all. In fact, he has carried art farther than any other man has done. He is not only a painter, but he is more; he is a great dramatist, second only to Shakespeare. Crabbe has been called the Hogarth of poets. There is a little resemblance between them; the song of the poet was of bumble vice, and villany, and corruption in rags; the satire of the painter dropped like aquafortis on the profligacy of the high, on those who, from station

and knowledge, should have set an example of worth and virtue. The aim of Hogarth was to represent life, to give us an image of man, to exhibit the workings of his heart for good or for evil, to shake us with mirth, rebuke us by satire, and sadden us into humanity by woeful reflection. Other painters lavished the hues of heaven on ladies of loose reputation; and made their paramours into gods—Hogarth dipped both in the lake of darkness, and held them up to the scorn and derision of mankind.

Reynolds is considered by the academicians as the founder of the British school of painting. To him they attribute the introduction of all that is vivid in colour or lofty in character. He did much, and was one of the first who, by his gentlemanly manners and probity, conferred dignity upon the profession of painter in our isle. The freedom, and ease, and breadth of colouring of his portraits are only equalled by the individuality of character which he gave to all he touched. They contain whatever was manly in man or gentle and lovely in woman. The happy looks and joyous eyes of his children are not more natural than the employments which he has assigned to them; they fondle birds, gather flowers, and chase butterflies, with a grace which it is vain to seek in the earlier artists of the land. His historical pictures are less happy; his imagination was of a humble order; he could not image out a virtue from reflection alone, nor impress the poetic costume of thought on his groups from the poets. Had angels condescended to sit, Reynolds would have found hues to limn them with. Those who desire to see how genius looked, or beauty demeaned herself, for half a century, in Britain, must consult the portraits of this great painter.

To the methodical talents of West we owe order and propriety. He is never extravagant; all his actions are decorously done; his characters think calmly, and work without effort or straining; but he is cold and unimpassioned. His figures are well shaped, and in graceful attitudes, but the spirit of life and thought has entered but partially into them; they seem moved by galvanism, more than by heart and soul. His battle scenes show none of that lofty animation and contempt of death which inspire those who, in the hour of extreme peril, triumph over thousands and tens of thousands. He painted scenes of peace and devotion, but the beholder is not touched in heart by the one, nor elevated in mind by the other; his hues, as well as his spirit, are sober. He was desired by George the Third—a monarch who had many fine qualities with but little poetic taste—to paint a

series of great pictures from the Christian worship and from British history—an order worthy of a great prince; and sore and long the artist laboured

“To reach the height of that great argument,”

with what success, let Windsor palace and chapel tell. We walk before the pictures suspended in those magnificent galleries with as little emotion as if the princes, and peers, and priests who fill the frames were so many shadows accidentally thrown on the wall, or the varied colours in which they are embodied were the passing hues of a rainbow.

Wilson created our poetic landscapes, Gainsborough that of English nature and humble life, and both are admirable. The former had visions of celestial mountains, with gods seated on their summits, nymphs singing on their sides, and the happy children of men disporting in sun-lit streams, shady forests, and “ruined temples grey.” The latter had less heavenly revelations; his hills are rocky, and rough with thorns, and are haunted by horned cattle instead of fawns and satyrs; on his greensward declivities he places smoking cottages and toiling hinds, while he gives life to his groves by strolling children and camps of roving gypsies, who tell fortunes and rob hen-roosts. Wilson has abundance of nature in his poetry, nor is Gainsborough without poetry in his nature.

Fuseli boasted that he alone brought poetry and learning to the service of art, and Barry lived and died in the belief that by his works the true spirit of historic painting was restored. On examining the productions of those audacious men, we can see little to vindicate their lofty pretensions. The former was all extravagance, the latter all coldness and mystery; and both were on the continual strain after a sublimity beyond their reach, and a sentiment too elusive to be rudely grasped. Fuseli possessed a genius fiery and impetuous, which allowed his hand to make no calm delineations; he could do nothing in a common way; his figures seem reeling with intoxication; his lovers meet and salute with an ecstasy as if, like Duncan’s horses, they would eat each other; his soldiers draw their swords like men possessed by seven devils; while his angels—light as well as dark—tumble to hell or ascend to heaven with anything save angelic calmness, and the serenity of conscious power. There is an eternal toil and trouble visible in too many of his pictures. Sometimes, however, he forgot himself—and then his creations were worthy of his genius—almost

of his pretensions. The works of Barry are equally deficient in propriety and imagination; they are prodigious mysteries, historical riddles; ancient times shake hands with latter, and Greek robes and English wigs jostle for precedence. He was afflicted with the desire of reading a grand historic lesson to mankind—and failed because no one understood his mysterious language.

Lawrence and Raeburn may be regarded as the true successors of Reynolds in portraiture, though who will venture to say that they have equalled him. The former was eminent for elegance and grace; his gentlemen are patterns of courtesy, and the looks of his ladies are radiant with beauty and love. The merits of the latter were of a sterner kind; he excelled in breadth and vigour, and expressed the character in mass, without descending to detail. To both we owe many noble portraits of inspired men; they bestowed their colours on the genius as well as wealth of the land, and genius will take pleasure in remembering them.

Northcote and Stothard may be named together—death and life are neighbours. The former teaches us what to shun, the latter is a model for imitation; both were of the academy, but one was made by the force of labour and Reynolds, the other by the force of study and nature. The figures of Northcote are shapeless and bloodless;

“There is no speculation in their eyes.”

He is continually striving to reach the heights of history or the depths of poetry; but he wants dignity for the one, and feeling for the other. The works of Stothard, on the other hand, are all natural elegance and unconstrained beauty. The daughters of England may be said to have inspired him with a true sense of beauty and modesty; for on whose canvass shall we find such unaffected loveliness, and such variety of female attraction? He is indeed very unequal, and a great mannerist, but he is original, and can never cease to be regarded as one of the greatest of British painters.

Historical painting seems at a stand in Britain; portrait painting is not on the advance, and no one will say that the landscapes of Wilson have been excelled, though the flights of Turner fairly rival him. In vivid pictures of social life, Wilkie has no superior; he has all the lively humour, tipsy jollity, and vivid presentment of character visible in the best Dutch artists, with a sentiment wholly his own. He has lately taken a step from the domestic into the historic, and painted two pictures, “Knox Preaching the Reformation,” and “Columbus in Spain,” which rival, in dignity of conception, force of character, and lucid depth and vigour of colouring, the noblest pictures of these our latter days. The Scripture landscapes of Martin are of a class by themselves; they realize the most terrible of the Old Testament scenes. The supernatural splendour of the “Handwriting on the Wall,” and “Joshua commanding the Sun to stand still,” can never pass from the mind of any one with either imagination or feeling. Two such distinguished painters fairly entitle us to claim a present pre-eminence over all other schools—and long may we retain it.

It cannot with truth be said that a true feeling and admiration of art is yet diffused over Britain. Works of high genius are rare matters. Like Milton's *Paradise Lost*, they are long in attaining all their fame, and require, with other mental efforts, serenity of mind, and something like public encouragement. To be the great merchants of the earth, and the rulers of the sea, seems the aim of the nation; yet this might be accomplished without discouraging either poetry or painting. At present, the angry parleys between political parties, and the feuds which inquiry, and love of change, and desire of reform have awakened in village and town, are injurious to literature and art. Perhaps, when the church is placed on a scriptural footing, and the balance of the constitution restored, the sun of public affection will shine as it ought on those studies which lead to true glory and permanent fame.

## HUNTER.

**HUNTER, JOHN**; a highly celebrated practitioner and writer on surgery, anatomy, and physiology, was born in Kilbride parish, Lanarkshire, on the 13th Feb., or, according to others, on July 14, 1728. His education was neglected, and he was, at first, apprenticed to a cabinetmaker; but hearing of the success of his elder brother in London, he offered his services to him as an anatomical assistant, and was invited by him to London, where he arrived in September, 1748. He improved so speedily, that, in the winter of 1749, he was able to undertake the instruction of dissecting pupils. In 1755, he was admitted to a partnership in the lectures delivered by his brother, in which situation he most assiduously devoted himself to the study of practical anatomy, not only of the human body, but also of brute animals, for which he procured from the Tower, and from the keepers of other menageries, subjects for dissection. He also kept several foreign and uncommon animals in his house for the purpose of studying their habits and organization. In the beginning of 1767, he was elected a fellow of the royal society. His first publication, a treatise *On the Natural History of the Teeth* (4to), appeared in 1771. In the winter of 1773, he commenced a course of lectures on the theory and principles of surgery, in which he developed some of those peculiar doctrines which he afterwards explained more fully in his published works. His perfect acquaintance with anatomy rendered him a bold and skilful operator, and enabled him to make improvements in the modes of treating certain surgical cases. But his fame chiefly rests on his researches concerning comparative anatomy. In 1776, he obtained the appointment of surgeon-extraordinary to the army. In 1781, he was chosen a member of the royal society of Gottingen, and in 1783, of the royal society of medicine and academy of surgery at Paris. In 1786, he published his celebrated work *On the Venereal Disease*. About the same time appeared a quarto volume, entitled *Observations on Various Parts of the Animal Economy*, consisting of physiological essays, most of which had been inserted in the *Philosophical Transactions*. His *Treatise on the Blood, Inflammation, and Gun-shot Wounds*, was one of the last of his literary labours. On the death of Mr Adair, he was appointed inspector-general of hospitals and surgeon-general to the army. He died October 16, 1793. His *Treatise on the blood, &c.*, was published in 1794, with an account of his life, by Sir Everard Home. Government purchased the museum of Hunter for £15,000, and transferred it to the royal college of surgeons, for the use of the public.

17.

**HUNTER, WILLIAM, M. D.**, elder brother of the preceding, and collector of the Hunterian Museum now in the university of Glasgow, was born May 23, 1718, at Long Calderwood, in the parish of Kilbride, eight miles from Glasgow, and, at the age of fifteen, was sent to that university, where he passed five years in studying as a candidate for holy orders. But having accidentally become intimate with Dr Cullen, then practising physic at Hamilton, he became disgusted with theology and commenced the study of medicine. In the year 1737, he went to reside with Cullen, and afterwards was received into partnership by him; but, in 1740, he went in the winter to Edinburgh to complete his studies, and in the summer of the year following went to London and lived as a pupil in the house of Dr Smellie the accoucheur. Having been the bearer of an introductory letter from Foulis, the learned printer of Glasgow, to Dr James Douglas, that physician took a great liking to young Hunter, and engaged him as his assistant in making dissections for a splendid work on the anatomy of the muscles, which he then was preparing to publish. The following year he had the misfortune of losing his father, and his patron, Dr Douglas, by death, but he still continued to reside in the doctor's family, superintending the education of his son, and attending St George's hospital, as a pupil, under Dr Frank Nichols.

Pursuing his anatomical studies with ardour, he, in 1745, communicated a paper to the royal society respecting the structure of the cartilages of the human body, and Sharpe, a lecturer on anatomy, having resigned in his favour, he commenced a course of demonstrations the same year. The profits arising from this first attempt amounted to seventy guineas, great part of which he very generously lent to some fellow students and lost. The next year he became a member of the college of surgeons, and practised surgery and midwifery, but at length confined himself entirely to that branch, in which he soon outstripped Dr Smellie, and was appointed accoucheur to the British lying-in-hospital. It was rather before this time that he spent some weeks on the continent, where he accompanied young Douglas through Holland and Paris; and having been greatly struck with seeing the anatomical museum, left by the great Albinus, at Leyden, it is conjectured that he then formed the design of emulating the labours of that celebrated anatomist. On the death of Sir Richard Manningham and resignation of Dr Sandys, he became first in his line of practice. In 1750, he obtained his Doctor's degree from the university of Glasgow, and then quitted Dr Douglas's family, and took a house in Jernyn

street; and, having been consulted on the pregnancy of the late queen, he was named one of the physicians extraordinary to her majesty, and was received into great favour by the king.

In the first volume of *Observations and Inquiries*, published by the Medical Society in 1757, appeared doctor Hunter's History of an Aneurism of the Aorta; and he was an important contributor to the subsequent publications of the society, of which he was chosen president on the death of Dr Fothergill. In 1762, he published a work, entitled *Medical Commentaries* (4to), to which was subsequently added a Supplement, the object of which was to vindicate his claim to some anatomical discoveries, in opposition to professor Monro, of Edinburgh, and others. In 1764, he was appointed physician-extraordinary to the queen. Doctor Hunter was elected a fellow of the royal society in 1767; and, in 1768, on the establishment of the royal academy of arts, he was appointed professor of anatomy. He was made a foreign associate of the royal medical society at Paris in 1780, and of the royal academy of sciences in 1782. The most elaborate and splendid of his publications, the *Anatomy of the Human Gravid Uterus* (folio, illustrated by thirty-four large plates), appeared in 1775. In 1777, he joined Mr Watson in presenting to the royal society a *Short Account of the late Doctor Maty's illness, and of the Appearances on Dissection*; and, in 1778, he published *Reflections on the Section of the Symphysis Pubis*, designed to show the impropriety and inutilty of that surgical operation, which had become fashionable among accoucheurs on the continent, and especially in France. Two *Introductory Lectures to his Anatomical Course*, which he had prepared for the press, were published after his death.

Being a bachelor he early began to lay aside a sum of money, such as he considered might be sufficient for his own wants, and appropriated the remainder of his income to some plan of public utility. As far back as 1765 he projected founding a great school of anatomy, and offered to ministers to expend £7000 towards it, if they would assist; but his projects were treated with cold indifference, and in 1770 he purchased and completed a house and theatre in Great Windmill street, in which he constituted a splendid museum. To this object he now devoted all his spare time and fortune, and its completion constituted the greatest pleasure of his life. At first he only contemplated a collection of preparations in human and comparative anatomy, but in 1761 he was tempted to become the purchaser of Dr Fothergill's collection of shells, corals, and other objects of natural history, for which he gave £1200, and when his friend Sir Robert Strange died, he purchased the pictures of that artist as well as those which belonged to Mr Foulis of Glasgow. But the most expensive part of his collection is that of ancient coins and medals, for the duplicates of which, after his death, government paid his executors £40,000, and added them to those in the British Museum. Of a part of this collection his friend Dr Combe published an elegant catalogue in 4to in 1783.

Dr Hunter had been subject to attacks of irregular gout as early as the year 1773, when he thought of relinquishing practice, and his death happened on the 30th March, 1783. On Saturday the 15th he had experienced a slight return of wandering gout, with headach and nausea, and been confined to bed. But feeling himself a little better, he got up to deliver an introductory lecture to a course of surgery, during which he was overcome suddenly with faintness, and was carried off and put to bed. This was on Thursday. On the Saturday morning he told his friends that he had suffered a paralytic stroke during

the night, but of which no traces remained, and died, a few hours before his death, to his friend Dr Combe, "If I had strength enough to hold a pen I should write how easy and pleasant a thing it is to die." In his last testament he bequeathed the whole of his splendid museum, valued at £150,000, to the university of Glasgow, with the sum of £8000 in cash, to be expended in an appropriate building for its reception, and a further sum of £500 per annum, to bear the charges of its preservation. To his nephew, Dr Baillie, he bequeathed his family property of Long Calderwood, but Dr Baillie very generously gave it to John Hunter, who had unfortunately had a quarrel with his brother Dr William some years before about some anatomical trifle. The museum was left subject to the liberent of Dr Baillie, who very handsomely relinquished it in 1808, when it was transferred to Glasgow, where it will long remain a glorious monument of the knowledge, enthusiasm, and public spirit of its founder.

HUNTING, in a general sense, includes the pursuit both of hairy and feathered game; but in a narrower sense, is applied only to beasts of venery (of the forest, as the hart, hind, hare, boar, wolf) and of chase (of the field, as the buck, doe, fox, marten, roe). In a rude state of society, it is one of the most important employments of mankind; and, in its more advanced state, becomes an agreeable amusement, men pursuing for pleasure, in the latter case, what they once followed from necessity. Hunting is practised in a great variety of ways, according to the object of the persons engaged in it, the nature of the country, and the description of the game. The object may be to obtain a supply of food, to destroy noxious animals, to get possession of useful ones, or of some useful animal product (as furs, &c.), or merely amusement. The pursuit may be conducted by means of other animals, as by dogs, falcons (see *Falcovery*), &c.; or the prey may be caught by stratagem (as by nets, traps, pitfalls), or destroyed by fire-arms, or other weapons, &c. A full account of the methods of hunting among the ancients may be found in the treatises of Xenophon (*Κυνεgetικα*) and Arrian (under the same title), and in the poem of Oppian—*Cynegetics*, or *On Hunting*. The breeds of hounds, their training and management, the hunting of the hare, the stag, the wild bear, lion, bear, &c.; the instruments, dress, &c., of the hunters, are minutely described with evincing keenness and great precision. Xenophon commences with Apollo and Diana, through whose aid the Centaur Chiron, on account of his love of justice, was rewarded with instructions in the science of the chase. Chiron, in turn, taught many eminent pupils. The treatise concludes with a general eulogy of hunting, which, we are informed, not only affords pleasure, but increases health, strengthens the sight and hearing, and pretracts the approach of old age. It is also the best preparation for military service. The author then goes on to prove that activity is the duty of every good citizen, and that the interests of his country, not less than the will of the gods, demand from each man all the exertion of which he is capable. To the passion for hunting which animated the feudal kings and nobles of Europe, the huge tracts of land which were afforested bear fearful testimony; and the writers of the time give a strong picture of the sufferings of the oppressed commonalty, under the tyrannical privileges of sport which were claimed by their masters. (See *Game Laws*.) It is unnecessary here to go into a minute description of the technical terms of hunting, or of the manner in which it is carried on. In England, the fox, the stag, and the hare are the principal objects of the chase; on the continent of Europe, the

Wild boar and the wolf are added to the list. See Daniel's *Rural Sports*.

The lion is hunted by horsemen on plains, and large dogs are used to dislodge him from his haunts. At the first sight of the huntsmen, he always endeavours to escape by speed, but if they and the dogs get near, he either slackens his pace, or quietly awaits their approach. The dogs immediately rush on, and, after one or two are destroyed, overpower him: twelve or sixteen are a sufficient match for him. The huntsmen keep together in pairs; if they have not a sufficient number of dogs, one of them, when within reach of the lion, dismounts and aims at the animal's heart; he instantly remounts, and his companion follows up the blow. In some parts of Africa, when a lion is discovered, the whole surrounding district is raised, a circle of three or four miles is formed, and the party proceeds, always narrowing the circle until the lion appears. He then springs on one of the party, who generally succeeds in killing him with a musket ball.

One of the noblest sports in the East is hunting the tiger, which is done in various ways, but chiefly by a numerous company of sportsmen, with elephants trained for the purpose, horses becoming ungovernable. When the retreat of the tiger is discovered, every attempt is made to dislodge him; the search is conducted with the largest and best trained elephant, which discloses the presence of the tiger by a peculiar kind of snorting and great agitation. The huntsmen, who are mounted on elephants, discharge their pieces, and, if the shot is not fatal, the tiger springs upon his assailants, who are often in great danger. Tigers are sometimes taken in traps, pits, or nets. The other animals of the feline species—the panther, leopard, &c.—are generally roused by dogs, and killed with fire-arms or arrows. The animals of the canine species, though less furious, are more cunning than those above mentioned.

The wolf has always been an object of human vengeance: in the East, it is hunted by eagles trained for the purpose; in Europe, the strongest greyhounds and other dogs are employed, and the chase is prosecuted either on foot or on horseback. It is, however, very difficult to run down a wolf, for it is stronger than a dog, and will easily run twenty miles, which, added to its stratagems, often renders the pursuit abortive. Wolves are also taken in traps and nets, though their vigilance and caution make it difficult to deceive them.

The most formidable animals of North America are the white bear and the grisly bear. They are ferocious, fearless, and extremely vivacious, and are hunted with arrows or fire-arms. The bison is destroyed by the North American Indians sometimes by riding in among a herd, and singling out one, which they wound with their arrows, until a mortal blow is given; or they drive a whole herd over a precipice. When flying before the pursuers, the herd rushes on with great rapidity, and it is impossible for the hunters to stop, as the main body pushes forward to escape the pursuit. The Indians nearly surround them, and rush forward with loud yells. The alarmed animals hasten forward in the only direction not occupied by their enemies, and are hurled over the precipice, and dashed to pieces.

HUNTINGDON, SELINA, countess of, the second daughter of Washington, earl Ferrers, was born in 1707, and married June 3, 1728, to Theophilus, earl of Huntingdon. Becoming a widow, she acquired a taste for the principles of the Calvinistic Methodists, and patronised the famous George Whitefield, whom she constituted her chaplain. Her rank and fortune gave her great influence, she was long considered to be the head of a sect of religionists; and, after the

death of Whitefield, his followers were designated as the people of lady Huntingdon. She founded schools and colleges for preachers, supported them with her purse, and expended annually large sums in private charity. She died June 17, 1791.

HUNTINGDON, WILLIAM; a religious enthusiast, who attained some notoriety towards the end of the eighteenth century. He was the son of a farmer's labourer in Kent, and the early part of his life was passed in menial service, and other humble occupations. After indulging in vice and dissipation for several years, according to his own account, he was converted, and became a preacher among the Calvinistic Methodists. He soon engaged in religious controversies, published a vast number of tracts, and was regarded as the head of a peculiar sect. He died in August, 1813, at the age of sixty-nine. He was a man of some talent, though little cultivated by education. His publications are very numerous, and some of them contain curious details relative to his personal history and religious experience. The titles of two may be mentioned as specimens: *The Arminian Skeleton*, or the Arminians dissected and anatomised (8vo); and *The Bank of Faith* (8vo). After having lost his first wife by death, he married the wealthy relict of Sir James Sanderson, a London alderman, and passed the latter part of his life in affluence.

HUNTINGDON, HENRY OF, an ancient English historian, was born towards the end of the eleventh or the beginning of the twelfth century. He was educated by Albinus of Anjou, a learned canon of the church of Lincoln. He composed a general history of England from the earliest accounts to the death of king Stephen, in 1154, in eight books, which have been published by Sir Henry Saville. Towards the conclusion, the author honestly acknowledges that it is only an abridgment, and allows that to compose a complete history of England, many books were necessary which he could not procure. Mr Wharton has published a letter of his on the contempt of the world, which details many curious anecdotes of the great men of his time.

HUPAZOLI, FRANCIS; one of the few individuals who have lived in three centuries. He was born in 1587, at Casal, in Sardinia, and died in 1702. At first, he was a clergyman, and afterwards became a merchant at Scio; and, in his 82d year, he was appointed Venetian consul at Smyrna. He had five wives, who bore him twenty-four children, besides which, he is known to have twenty-five illegitimate children. By his fifth wife, whom he married at the age of ninety-eight years, he had four children. His drink was water; he never smoked, and ate little (principally game and fruit). He drank a good deal of the juice of the *scorzonera* root, ate but very little at night, went to bed and rose early, then heard mass, walked and laboured the whole day to the last. He wrote down every thing remarkable which he had witnessed, in twenty-two volumes. He never had a fever, was never bled, and never took any medicine. At the age of 100, his gray hair again became black. When 109 years old, he lost his teeth, and lived on soup. Four years later, he had two large new teeth, and began again to eat meat. During the latter part of his life, he had, for almost thirty years, monthly evacuations of blood. After these ceased, he was afflicted with the stone, and frequent colds, which continued until his death. He was of a mild temper. His principal fault was his passion for the other sex. Hupazoli was rich, and had but few wants.

HURD, RICHARD; an eminent English prelate and philological writer of the last century. He was born January 13, 1720, at Congreve, in Stafford-

shire, went to Emanuel college, Cambridge, in which he obtained a fellowship in 1742, and, in 1749, published *Horatii Ars Poetica, Epistola ad Pisones*, with an English commentary and notes. In 1750, he published a Commentary on the Epistle of Horace to Augustus. A satirical attack on doctor Jortin, in defence of Warburton, in an Essay on the Delicacy of Friendship, he afterwards endeavoured to suppress. In 1757, he published Remarks on David Hume's Essay on the Natural History of Religion (8vo). His Dialogues, moral and political, with Letters on Chivalry and Romance, appeared at different times, from 1758 to 1764, and were republished collectively, in 1765 (3 vols. 8vo). None of his works attracted so much notice as the dialogues, which were translated into German by Holty. In 1767, he was made archdeacon of Gloucester, and, in 1768, commenced a series of sermons on the prophecies, preached at the lecture founded by his friend Warburton at Lincoln's Inn. These discourses were published under the title of an Introduction to the Study of the Prophecies concerning the Christian Church, in twelve Lectures (1772). In 1775, doctor Hurd was raised to the bishopric of Litchfield and Coventry; and, not long after, was made preceptor to the late king, and his brother the duke of York. He was translated to the see of Worcester, in 1781, and, at the same time, was bestowed on him the confidential situation of clerk of the closet. The king afterwards desired to elevate doctor Hurd to the primacy, but he modestly declined the offer. In 1788, he published an edition of the works of bishop Warburton, in which he omitted some of the productions of his deceased friend. Doctor Parr supplied the editorial deficiencies of bishop Hurd's collection, by Tracts by Warburton and a Warburtonian. In 1795, the right reverend editor himself published a kind of supplement to the works of Warburton, in the form of a biographical preface, and he subsequently also published the correspondence of Warburton, which was his last literary undertaking. He died in May, 1808.

**HURON**; a lake of North America, 218 miles long, from east to west, and 180 broad, of very irregular form; about 1100 miles in circumference, containing many islands and bays; lon. 80° 10' to 84° 30' W.; lat. 43° 20' to 46° 10' N. It abounds in fish, which are similar to those in lake Superior. Some of the land on its banks is very fertile, and suitable for cultivation; but in other places, barren and sandy. The promontory which divides the lake from lake Michigan, is composed of a vast plain, upwards of 100 miles in length, but varying in its breadth. At the north-east corner, the lake communicates with lake Michigan, by the straits of Michilimackinac. On its banks are found amazing quantities of sand cherries, and in the adjacent countries, nearly the same fruits as about the other lakes.

*Huron River*, or *St Clair River*, connects lake Huron with lake St Clair. It is 40 miles long, and about one mile wide.

**HURONS**; a tribe of North American Indians, which was formerly numerous, and dwelt on the east of lake Huron; but, in 1650, they were driven out by the Iroquois, and retired to the south-west of lake Erie. The Six Nations (the Mohawk tribes or Iroquois) call the Hurons *father*, without doubt because they are descended from the Hurons, who are now reduced to 700 warriors. They are among the most civilized of the North American Indians, live in good houses, have horses, cows, and swine, and raise grain for sale. Their proper name is *W'yandots*. (See *North American Review*, vol. 24, pp. 419, 428.) The Iroquois are sometimes included under the name of Hurons, but they are a separate people.

**HURRICANE** (in Spanish *huracan*; in French, *ouragan*; in German, *orkan*); a word, according to the most probable supposition, picked up by voyagers among the natives of the West Indies; properly a violent tempest of wind, attended with thunder and lightning, and rain or hail. Hurricanes appear to have an electric origin: at the moment that the electric spark produces a combination of oxygen and hydrogen, a sudden fall of rain or hail is thus occasioned, and a vacuum formed, into which the circumbient air rushes with great rapidity from all directions. The West Indies, the Isle of France, and the kingdoms of Siam and China, are the countries most subject to their ravages. What are called hurricanes, in the more northern latitudes, are nothing more than whirlwinds, occasioned by the meeting of opposite currents. But in the real hurricane, all the elements seem to have armed themselves for the destruction of human labours and of nature herself. The velocity of the wind exceeds that of a cannon ball; corn, vines, sugar canes, forests, houses, every thing is swept away. The hurricane of the temperate zone moves with a velocity of about sixty feet a second; those of the torrid zone, from 150 to 300 feet in the same time. They begin in various ways; sometimes a little black cloud rolls down the mountains, and suddenly unfolds itself and covers the whole horizon; at others, the storm comes on in the shape of a fiery cloud, which suddenly appears in a calm and serene sky.

**HUSBAND AND WIFE**. Of all private contracts, that of marriage is most intimately blended with the social condition of a community, and gives rise to the most numerous and important relations, rights, and duties. It was for this reason, in part, though still more, perhaps, from the desire of dominion and jurisdiction on the part of the clergy in former times, that this contract was invested with a peculiar religious character, and made one of the *seven sacraments* of the Catholic church. Marriage, accordingly, is often celebrated in places of public religious worship, in both Catholic and Protestant countries; and the ministers of religion, even in countries where the church has no judicial jurisdiction whatever over the rights arising from this contract, still officiate, for the most part, at its solemnization. (As to the forms of solemnizing marriage, and as to its dissolution, the reader is referred to the respective articles *Marriage* and *Divorce*.) The first and one of the most important rights resulting from this contract, is the control, in a greater or less degree, according to the laws of different countries, which it gives to the husband of the person of the wife. The terms in which this right is expressed, in the laws of England, are stronger than those of the civil law, or the modern codes derived from it. But this right is still recognised in those codes, of which that of France may be referred to as an example. The old writers in the English law express themselves more directly upon this subject than is grateful to modern ears, putting the authority of the husband upon a footing similar to that of a parent over a child, or a master over a servant; and, in this case, as in those, they very compositely lay down the rules and limits of the exercise of this authority, describing the degree of coercion permitted by the law to be used, and the degree of correction which it allows to be administered by the husband. In modern times, these doctrines are expressed in more cautious and qualified terms, and some writers are careful to reserve to the wife some corresponding rights. However the mutual rights of the parties in this respect are to be construed and reconciled, it is certain that the English law distinctly recognises the husband's right to

the personal services of his wife; and, in the action by the husband against another on account of criminal conversation with the wife, direct allusion is made to this marital right, while the wife has no corresponding action against a woman who does her a similar injury. In respect to the children—as a divided authority, where the voices would be equal would lead to embarrassment—the law assigns the guardianship and authority over them to the father, to which the mother succeeds, in a great degree, on his decease, but not wholly, for the children may, at a certain age in their minority, choose guardians for themselves, in case of the father's decease.

As the law assigns a certain ascendancy to the husband, so it provides some compensation, by imposing upon him stronger and more extensive obligations; and both the authority and the obligations of the husband are more extensive where the common law of England has sway than where the Roman law is the fountain of civil jurisprudence. As this common law, according to its original spirit and usual operation, leaves the wife destitute of the means of supporting herself, it imposes upon the husband the obligation of supporting her, in the most direct and absolute terms. His duty to provide for the support of the children is no less imperatively enjoined by the law, to which duty the wife succeeds, in its full force, in case of the decease of the husband. In either case, the duty extends to the utmost ability and means of the party. In respect to the distinct possession of property, and distinct civil abilities of the two parties, in regard to the acquisition and management of property, the common law of England and the codes springing from the Roman law are widely different, and give rise to the most striking diversities in the civil relations of families under the jurisdiction of these respective systems.

By the theory, as well as the practical administration of the common law of England, which has not been very deeply trenching upon by statutes or judicial modifications, the civil rights and abilities of the wife are mostly merged by the marriage. The husband and wife are considered, in law, to be one person, and that one person recognised by the law is the husband. By the very act of the marriage, the chattels of the wife become the property of the husband. He has a right, also, to collect all the debts due to her; but then he also, at the same time, incurs a corresponding obligation, for he at once becomes liable to pay all her debts. Though, in bringing suits, after the marriage, for the debts due to the wife before marriage, the names of both the husband and wife are used as plaintiffs and creditors, yet, when the debts are collected, the proceeds are at the absolute disposal of the husband. So the rents and income of the wife's real estate, during the continuance of the conjugal connexion, belong to the husband as absolutely as if the estate itself were his own; but he cannot sell the estate without the concurrence of the wife, and, in England, such a sale can be made only under judicial cognizance, by a proceeding in which the wife must appear personally in court, and express her assent to the sale. In the United States of America this precaution is not taken, though, in some of the states, the wife must be examined separately from her husband, by some magistrate authorized to take the acknowledgment of deeds; and, on her acknowledging that she, freely, and without constraint by the husband, assents to the sale, the conveyance will be good; while, in other states, no such separate examination is required, but she may execute the deed either in the presence or absence of her husband, as the law may provide in this respect. If the wife has already commenced a suit, at the time of the marriage, the husband's con-

trol of the claim for the demand in suit is considered to be so direct and absolute, that the defendant is no longer liable to answer to the wife, and the suit will be defeated on the defendant's objecting to its being further prosecuted in her name; for the common law does not allow the husband, in such case, to come in and join in the prosecution, though there seems to be no very good reason why it should not. In such case, the proceedings must be commenced anew, in the names of both. If a suit is pending against the wife at the time of the marriage, it does not abate, for the law will not permit the rights of third parties to be injured by the voluntary act of the defendant, but such suit proceeds as if no marriage had taken place, or the husband is cited in and made a co-defendant in the suit. The same principles extend to all the civil relations of the wife. If she was acting as executrix on an estate, the husband, on the marriage, becomes executor with her. So if she is appointed executrix during the marriage, the husband is executor with her; and so where imprisonment for debt is permitted, the law does not allow the wife to be imprisoned on execution for her own debt, separately from her husband, but he must be imprisoned with her; and if he escapes from prison, and is not retaken, after a reasonable time allowed for this purpose, the wife will be discharged.

On the dissolution of the marriage by the death of the husband, or by a divorce from the bonds of matrimony, the civil abilities of the wife revive, and she will then also be entitled, in her own right, to the rents and income of her real estate accruing subsequently, and she will also be entitled, in her own right, to all the debts due to her before the marriage, and which the husband has not appropriated to himself. But, as all the earnings of the wife, during the marriage, belong exclusively to the husband, whether gained by her labour, by trade, or in any other way, he alone can sue for any claim thence arising; and, in case of his decease, his executors succeed to his right, and not the wife in her individual capacity. The law, at the same time, shows a scrupulous respect for a union so intimate, and permits the parties mutually to defend each other against the attacks of other persons; and also exempts them, except in a few extreme cases, from being witnesses against each other, upon the same principle on which it exempts a party from being a witness against himself; and even farther, for it will not permit either to be a witness against the other.

It is a general rule, that this contract of marriage so completely absorbs all others, that the parties cannot afterwards contract with each other, since, in the view of the law, it would be equivalent to a contract of a party with himself. In the time of lord Mansfield, some decisions were made by the court of king's bench, in England, tending to the introduction of an exception to this doctrine, in case of an agreement between husband and wife to live separately, upon formal articles made by them, providing for a separate maintenance of the wife. But the same court retraced its steps, in the time of the succeeding chief justice, lord Kenyon, and re-established the old doctrine, that all such agreements were absolutely void. The only way, accordingly, of protecting and maintaining the pecuniary contracts of the wife, and preventing them from being merged by the marriage, is through the intervention of trustees. The law does not prevent the putting property into the hands of trustees, to be managed either according to the discretion of the trustees, or under the direction of the wife, for her separate benefit, as if she were a single woman; and this may be done either before or after the marriage, provided that the interest of creditors, having subsisting claims at the time,

shall not be affected. So that, after all, this civil identity of the husband and wife, as to the possession, use, control, and application of the wife's property, or its income, is merely nominal, since the law permits to be done in the name of another what it does not permit in her own. And, where there are courts established with sufficient powers to give suitable remedies in regard to such contracts (as there ought, undoubtedly, to be every where), any provisions and conditions may be agreed upon between the parties, as to any property already existing. Such contracts are, however, collateral to that of marriage; for the law will by no means allow of any conditions or modifications to the contract itself.

In countries where the civil institutions are borrowed from the Roman law, as has already been said, the conjugal bond, of its own force, and according to the general laws, independently of any express stipulations of the parties between themselves, or of the intervention of any third parties, gives rise to a very different set of relations and rights. To take the French code, for an example, without going into an inquiry how far the laws of other countries, derived from the same source, coincide with that code in minor details and provisions, there are two descriptions of marriage contract, as far as the property of the parties is concerned, both of which, however, contemplate the rights of property of the parties as distinct. By one form of the marriage contract, the husband and wife become partners; by the other, their rights of property continue distinct, notwithstanding the marriage. In case of no stipulation, a community of goods will, by the operation of law, result from the marriage; so that a special agreement is requisite, in order to maintain a separate property in each party; and this is called a *dotal* marriage, or one in which the wife's *dot*, or *portion*, is regarded as a distinct property. If the marriage is intended to be a dotal one, it must be so expressed, in a formal instrument, drawn up before a notary public; and thus the same object is effected, which, under the jurisdiction of the common law of England, can be secured only by the interposition of a third party, and a set of minute and elaborate provisions, creating a trust. The French code does not, however, any more than the English common law, permit any conditions or modifications to be introduced into the marriage contract itself, which makes the personal rights of the parties the same throughout the kingdom; and, in respect to the rights to property, and its possession and use, it does not, like the English common law, affect at all to consider the parties as identified. This community of goods extends to all the movable property of the parties, possessed at the time of the marriage, and to all that is acquired by them during the continuance of the conjugal relation, as well what accrues from their industry, and the use of their property, as that which comes by descent or donation, unless the donation is upon other conditions prescribed on the part of the donor; but, on the dissolution of the partnership, or community of goods and interests, whether by the death of one of the parties, or otherwise, a division is made between them, or between the survivor and the heirs of the deceased partner, as in the case of an ordinary partnership; but, if the marriage is dotal, the wife's portion, or its value, will continue to be her separate property; but still, unless it be otherwise agreed, the management and income of it will belong to the husband, who is not obliged to give any sureties for his proper management of the trust, unless it shall be so stipulated by the parties. If this separate property consists of lands, neither the husband alone, nor both parties concurring, can dispose of it during the marriage. In general, this separate property, or

its value, must eventually, on the dissolution of the marriage, like the wife's share in the partnership funds in the case of community of property, go to the wife, or her representatives. There are, however, certain cases in which a part or the whole of the capital, of which the portion consists, may be alienated during the marriage; as, for instance, to obtain the release of the husband from prison, to supply the means of support to the family, and in a few other specified cases; but in general, it is to remain the separate property of the wife, and, as such, whether it consists of personal or real estate, descends to her heirs.

HUSKISSON, WILLIAM, the right honourable, a political character of the present century, who distinguished himself chiefly in matters of finance and the commercial relations of the country, was born in 1769, and sent to Paris, while quite young, to study anatomy and medicine. On the breaking out of the French revolution, he was warmly disposed to the liberal side of the question, and was an active member of the London corresponding society, though not, as has been said, of the Jacobin club at Paris. He was soon after, however, introduced to the notice and favour of Mr Pitt, and, in 1794, was placed in the office of Mr Dundas (lord Melville), then secretary of the home department. In 1801, he was appointed receiver-general of the duchy of Lancaster, and a commissioner of trade and plantations. He soon after entered parliament as member for Morpeth. Here Mr Huskisson did not speak much, but was very useful to the ministry in financial matters, both in parliament and in preparing papers. When Mr Canning's difference with lord Castlereagh induced him to leave the ministry (1809), Mr Huskisson retired with him, and in subsequent debates it soon appeared that a third party existed in the house, agreeing with the ministry on questions of general policy, but joining the opposition in demanding retrenchment in the public expenditure. On the appointment of Mr Canning to the foreign secretariat, Mr Huskisson entered the cabinet with him as president of the board of trade. In the Goderich ministry, he became secretary for the colonies, and retained that post in the Wellington ministry, composed of the warm enemies of his late friend, Mr Canning; but it was soon apparent that no cordial co-operation could take place between men of such opposite principles, and Mr Huskisson and his friends were soon obliged to withdraw. His death took place Sept. 15, 1830. Being present at the celebration on the opening of the Liverpool and Manchester railway, he came inadvertently in the course of one of the steam-carriages, moving at a rapid rate, which passed over him, and crushed one of his legs in consequence of which he died next day.

HUSS, HUSITES. John Huss was born in 1373, at Hussinec, near Prachatitz, in Bohemia, whence he acquired the name of *Huss*, or *John of Hussinec*. In 1389, he was sent, by his feudal lord and some other patrons, to the university of Prague, where he was distinguished for his talents and industry. Having become the servitor of a professor, to whose library he thereby had access, he had an opportunity of acquiring a degree of theological information, which, for that age, was remarkable. In 1396, he took the degree of master of arts, and, in 1398, delivered public theological and philosophical lectures. In 1402, the office of Bohemian preacher in the Bethlehem chapel at Prague, which was established by a private foundation, was conferred on him. Here he began to acquire influence over the people, with whom, as well as with the students, his sermons were very popular; and, being soon after made confessor to the queen Sophia, he thus gained access to

the court. At this time, he became acquainted with the writings of Wickliffe. His knowledge of the Scriptures soon made him feel the justice of that bold reformer's attacks on the abuses of the church, and he now became himself the boldest advocate of a reform which should restore to the corrupt church the simplicity and purity of scriptural Christianity. His boldness did not long remain unobserved; and as, in the frequent disputes of the Germans with the Bohemian academicians, he took part with the latter, he had soon to contend with powerful enemies. This made a national division of that which hitherto had been only a contest between the philosophical schools of the Realists, to which Huss belonged, and of the Nominalists, to which most of the Germans had attached themselves. About 5000 foreign professors and students left Prague, and either created or gave a new impulse to the universities of Leipsic, Erfurt, Ingolstadt, Rostock, and Cracow, a loss which Prague and Huss himself, who was now a rector, sensibly felt. Yet he could not be attacked in Bohemia; the great schism had exposed the weakness of the priesthood; Bohemia did not recognise Benedict XIII., nor Gregory XII., after 1409; the nobility and people were excited against the arbitrary decrees of the pope, by some bold spirits, who served as the precursors of Huss's doctrines, and thus became accustomed to judge freely; the government of Wenceslaus favoured the anti-papal spirit of many among the people, from political grounds, and from an inclination favourable to Huss, who was generally esteemed. He ventured, therefore, to censure publicly the corrupt morals of the priests and the laity, and to preach against the sale of papal indulgences in Bohemia; he said nothing new, when he declared masses for the dead, image-worship, monastic life, auricular confession, fasts, &c., to be inventions of spiritual despotism and superstition, and the withholding of the cup at the Lord's supper unscriptural. The new pope, Alexander V., finally summoned him to Rome, and, as he did not appear, the archbishop of Prague, Sbynko, commenced the immediate persecution of this preacher of the truth. About 200 volumes of copies of Wickliffe's writings were burnt in 1410, in the archbishop's palace, and the Bohemian preaching at the Bethlehem chapel prohibited. But Huss did not obey either this prohibition or the new summons of John XXIII., but appealed, as his envoys at Rome were imprisoned, to a general council.

When the pope caused a crusade against Ladislaus of Naples to be preached in Bohemia, Huss opposed it in the warmest manner, and his friend Jerome expressed himself on the subject in violent language, which the pope ascribed to Huss, who was, in consequence, excommunicated, and Prague laid under an interdict as long as Huss should remain in it. Huss, therefore, distrustful of the protection of the weak king of Bohemia, went to the feudal lord of his birthplace, Hussines, whose name was Nicholas. Here, and in many places in the circle of Bechin, he preached with much success; here he also wrote his memorable books *On the Six Errors*, and *On the Church*, in which he attacks transubstantiation, the belief in the pope and the saints, the efficacy of the absolution of a vicious priest, unconditional obedience to earthly rulers, and simony, which was then extremely prevalent, and makes the holy Scriptures the only rule of matters of religion. The approbation with which these doctrines were received, both among the nobility and common people, increased the party of Huss in a great degree; and, as nothing was nearer to his heart than the diffusion of truth, he readily complied with the summons of the council of Constance to defend his opinions before the clergy of all

nations. Wenceslaus gave him the count Chlum and two other Bohemians of rank for his escort. The emperor Sigismund, by letters of safe conduct, became responsible for his personal safety, and John XXIII., after his arrival at Constance, November 4, made promises to the same effect. Notwithstanding this, he was thrown into prison, November 28, after a private examination before some of the cardinals, and, in spite of the reiterated remonstrances of the Bohemian and Moravian nobles, was kept in confinement, and, though sick, was not permitted an advocate. At a public examination, June 5, 1415, the fathers of the council interrupted him in his defence by loud and vehement vociferation. In a trial on the 7th and 8th of June, he defended himself at length, in the presence of the emperor; but his grounds of defence were not regarded, and an unconditional recantation of heresies which he had not taught, as well as those which he had, was demanded of him. Huss, however, remained firm in his belief, and the last examination (July 6) eventuated in a sentence of death, which had long since been determined on. Huss on this occasion reminded the emperor of his promise of safe conduct, at which Sigismund could not refrain from showing his shame by a blush; yet the hatred against a man who had ventured to speak the truth was too great to allow any hopes of safety. He was, without being convicted of any error, that same day burnt alive, and his ashes were thrown into the Rhine. On his way to the pile, he was observed to smile at a place where some of his writings had been burnt, and afterwards expired in the midst of joyful prayers. Even his enemies speak with admiration of his unblemished virtue and his firmness in the hour of death.

*Hussites.* The gentle and pious mind of Huss would not have approved of the terrible revenge, which his Bohemian adherents took upon the emperor, the empire, and the clergy, for his death, in one of the most bloody and terrible wars ever known. The decrees and excommunications of the council were despised in Bohemia. Instead of destroying the new doctrines, the *auto-da-fé* of Constance was the watchword of union for multitudes of all classes, who, from their teacher, were called *Hussites*. Wenceslaus was compelled, in 1417, to grant them many churches for the celebration of the sacrament in both forms, and as their number increased every day, there were soon many among them who wished for something more than mere religious freedom. The wavering and temporising conduct of this king (who died August 13, 1419) and the inquisitorial violence of the cardinal legate, John Dominico, kindled the fire of insurrection. The people could not, however, set aside the claims of the hated emperor Sigismund to the vacant throne. Always bent upon the extirpation of heretics, faithless in treaties, and unequal to contend with the activity of the Hussites, and the genius of their generals, he was obliged to see the kingdom which he had inherited in a state of anarchy for fifteen years. The Hussites commenced their rebellion by a bloody vengeance on the Catholics; their convents, many of which, in Bohemia, were more splendid than elsewhere, and their churches, were plundered and burnt, and the priests and monks murdered. John Ziska of Trocnaw, a Bohemian knight, formed of the large bodies of people which were constantly flocking to him, a well mounted and disciplined army, which, in its barricado of wagons, repelled all attacks, and built the fortified city of Tabor, for a place of arms and a point of defence, upon a mountain consecrated by the field preachings of Huss, and strong by nature, in the circle of Bechin. The oldest friend of Huss, Nicholas of Hussines, commanded under this general. Nicholas

was well known for the courage with which he had, in 1417, placed himself at the head of the Hussites, and beaten and driven from Tabor the faithless Ulrich of Rosenberg, together with the imperial army, in 1420. He resisted, from patriotic motives, the plan of the inhabitants of Prague, to choose a foreign prince for a king, but died, too soon for the welfare of Bohemia, December 25, 1420, with the glory of having been rather a defender of the faith of Huss, than a persecutor of the Catholics.

In this persecution, Ziska was the most zealous and most cruel—*Ziska of the cup*, as he was called, chief of the *Taborites*, as the Hussites under his banner designated themselves, from their city. The strength of his army, and his victories over the imperialists gave him an influence in the Bohemian affairs which was nearly allied to that of a protector. But when the murders and devastations of his army, and of the small bands which made the religious war a pretext for plunder, continually increased, the most moderate Hussites of the nobility, and the citizens of Prague, whose chief concern was the allowance of the cup to the laity at the sacrament (thence called *Calixtines* or *Praguers*), and the quiet of the kingdom, were induced to offer the Bohemian throne, first to Ladislaus, king of Poland, then to the grand prince Vitold, of Lithuania, and at last to his nephew Koribut. But Ziska, with the *Taborites*, dissented, and the difference of these parties, which had appeared in the diversity of their demands for a church reform, now produced a real division. Nothing was more dangerous to the cause of the Hussites than the multitude of sects and parties in Bohemia; each, since 1421, acted by itself, and they only united against the common enemy, in order that, as soon as he was routed, they might again quarrel with each other. Ziska having become totally blind at the siege of Raby, and victorious over the imperialists, whom he defeated in the great battle of Deutschbrod, and continually successful in small contests against the nobility, who lost immensely by his ravages, without being able to place any limit to them, and against the inhabitants of Prague, who preserved their city from destruction only by a hard and short-lived peace, Sept. 14, 1424, died October 12, of the same year, of the plague. At his death, the fearful mass, which only his military talents and good fortune had held together, fell to pieces. The majority of the *Taborites* elected for their general Andrew Procopius, who had been recommended by Ziska, and who, having been at first destined to the church, is called the *Shorn* (Holy, *rasus*). Koribut, a mere shadow of a king, had been chosen by the inhabitants of Prague, in 1422, and, although he had routed Busso of Vitthum with the strongest army which Saxony had ever produced, June 16, 1426, at Aussig, was not able to control the ferocity and plundering propensity of the parties among the Hussites, and was obliged to abdicate the throne, in 1427. Procopius showed himself worthy of his predecessor. The decisive victories which he gained in July, 1427, and August 14, 1431, at Miss and Tachau, over the army of the cross, composed of the people of the German empire, and far superior to the Hussites in number, made the arms of the latter not less formidable than the devastating expeditions, which the detached bodies of partisans carried on against the neighbouring states almost every year from the beginning of the war until 1432. Austria, Franconia, but especially Saxony and those provinces of Bohemia which were yet obedient to the pope, Lusatia and Silesia, were the theatre of the most horrid cruelties and robberies. All parties were now desirous of peace; and, as the German arms were unsuccessful against the Hussites, the council of

Basle saw itself compelled by Sigismund, who had always retained a faction among the Bohemian nobility and the inhabitants of Prague, to come to terms with the heretics; and thus, Nov. 20, 1433, a compromise was made (the compact of Prague), which, however, was not received by all parties, and hostilities recommenced, but were ended by a complete victory of the Calixtines and Catholics under Meinhard of Neuhaus, at Bomischbrod, May 30, 1434. The Calixtines, who were now superior, in conjunction with the Catholic states, chose the emperor Sigismund for their king, who swore at Iglaa, July 5, 1436, to adhere to the compacts, which had been rendered somewhat easier by the council, in compliance with the wishes of the Calixtines, but was again faithless to his promise, and died, Dec. 9, 1437, without having restored perfect quiet to Bohemia. The *Taborites*, very much weakened, were able to maintain their dispute only in the deliberations of the diet, and in theological controversial writings, whereby their confession of faith acquired a purity and a completeness which made it similar, in many respects, to the confessions of the Protestants of the sixteenth century; but their religious freedom continually suffered more and more, until they merged in the fraternity of Bohemian and Moravian Brethren, which arose in 1457, and, under the most violent persecutions, exhibited an honourable steadfastness and purity. See *Bohemian Brethren*, and *United Brethren*.

**HUSSARS**; originally, the name of the Hungarian cavalry, raised in 1458, when Matthias I. ordered the prelates and nobles to assemble, with their cavalry, in his camp. Every twenty houses were obliged to furnish a man; and thus, from the Hungarian words *huzar* (twenty), and *ar* (pay), was formed the name *Huzar*, *Huszar*. The arms and dress of this light cavalry were afterwards imitated, and the name borrowed by other nations.

**HUSTINGS**, COURT or; the principal court in the city of London, of great antiquity, held before the lord mayor and aldermen in London, the sheriffs and recorder in Guildhall. The derivation is uncertain. In a popular sense, it is used in England for a place raised for the candidates at elections of members of parliament, perhaps from *hoistings*.

**HUTCHESON**, FRANCIS, LL. D., an ingenious philosophical writer, was born in the north of Ireland, August 8, 1694, and, in 1710, was entered a student in the university of Glasgow. After spending six years at Glasgow, he returned to his native country, where he was licensed to preach among the Dissenters, but accepted the invitation of some gentlemen acquainted with his talents, to set up a private academy in Dublin. In 1725, the first edition of his celebrated *Inquiry into the ideas of Beauty and Virtue* appeared without his name; but its merit would not allow the author to be long concealed. In 1728, he published his *Treatise on the Passions*, which has often been reprinted, and is admired even by those who dispute the soundness of its philosophy. In 1729, he was called to the chair of philosophy at Glasgow. He died in 1747, in his fifty-third year. In 1755, was published, from his MSS. a *System of Moral Philosophy* (in three books, 2 vols 4to); to which is prefixed some account of the Life, Writings, and Character of the Author, by Doctor Leechman, Professor of Divinity in the University of Glasgow. The system of morals of Doctor Hutcheson is founded upon nearly the same principles as that of Lord Shaftesbury. He deduces all our moral ideas from an implanted moral sense or instinct, like that of self-preservation, which, independently of argument, or the reasonableness of certain actions, leads us to perform them ourselves, and to approve them in others.

His works and lectures contributed to diffuse a taste for analytical discussion in Scotland, which led to the production of some of the most valuable writings of the eighteenth century.

HUTCHINS, THOMAS, geographer to the United States of America, was born in New Jersey, about 1730. He entered the army in the French war, and served at fort Pitt and against the Indians in Florida. He was imprisoned in England, in 1779, on the charge of having corresponded with doctor Franklin, then American agent in France. On recovering his liberty, he joined the army of general Greene at Charleston. He was nominated geographer-general to the United States; and died at Pittsburgh, in 1789. He published an *Historical Sketch of the Expedition of Bouquet against the Indians of Ohio*, in 1764; a *Topographical Description of Virginia, Pennsylvania, Maryland and Carolina*, with maps (London, 1778); a *Historical Account and Topographical Description of Louisiana, West Florida, and Philadelphia* (1784).

HUTCHINSON, ANN, a religious enthusiast, who occasioned dissensions in the churches of New England, came from Lincolnshire to Boston, in 1636. She instituted meetings for women, in which, pretending to enjoy immediate revelations, she taught many Antinomian and other sentiments, which soon occasioned great controversy in the colony, and, in 1637, drew together an ecclesiastical synod, which condemned her errors. Not long after, she was banished from the colony, and removed to a Dutch settlement in New York, where, in 1643, she, and her family, consisting of fifteen persons, were captured by the Indians, and all except a daughter killed.

HUTCHINSON, THOMAS, a governor of the colony of Massachusetts, was of a family distinguished in the annals of New England, and was born in Boston, in 1711. After graduating at Harvard college, in 1727, he became a merchant; but, not succeeding in trade, engaged in the study of law and politics, in order to qualify himself for public life. He was sent to London to transact some business for the town of Boston, which charge he executed satisfactorily, and, on his return, was elected a representative. He was, after a few years, chosen speaker of the house, and, in 1752, succeeded his uncle as judge of probate. He was placed in the council, and was appointed lieutenant-governor in 1758, and chief-justice in 1760—all of which offices he held simultaneously for several years. In 1771, he received his commission as governor of Massachusetts. It is affirmed that there was no single officer of the British government in America, who contributed more to produce the separation of the two countries than Hutchinson. His ambition and avarice were such as to render him completely subservient to the views of the British ministry, and to cause him to sacrifice his principles, in order to abet every arbitrary regulation, and to suggest the most odious means of enforcing them. He went so far even as to challenge the legislature to a discussion of colonial rights, which, he believed, he could convince them by argument that they did not understand, and ought to abandon. For some time, he enjoyed considerable popularity in the province, in consequence of his attention to business, and the circumstances of his being a native, and not a member of the English church. But the publication of several of his letters to the ministers, which had fallen into the hands of Doctor Franklin in London, and by him had been transmitted to Boston, by which the people became aware of his hypocrisy, and of the odious counsels which he had given against their rights, combined

with his obstinacy in preventing the obnoxious tea from being returned to the ships, so exasperated them, that his recall was rendered indispensable. In the year 1774, accordingly, he was removed from his office, and general Gage was put in his place. He then repaired to England, where, for some time, he was fed with expectations of favour: but, after it was found by the British ministry to be a more difficult matter to conquer the Americans than he had led them to suppose, he fell into disgrace, and lived in the most retired way, near Brompton, until his death, June 3, 1780, in his sixty-ninth year.

The following extract of a letter from president Adams to William Tudor will give an idea of governor Hutchinson's condition in London: "Fled, in his old age, from the detestation of a country where he had been beloved, esteemed, admired, and applauded with exaggeration; in short, where he had been every thing from his infancy, to a country where he was nothing; pinched by a pension, which, though ample in Boston, would barely keep a house in London; and throwing round his baleful eyes on the exiled companions of his folly; hearing daily of the slaughter of his countrymen, and conflagration of their cities; abhorred by the greatest men and soundest part of the nation, and neglected, if not despised, by the rest—hardened as had been my heart against him, I assure you, I was melted at the accounts I heard of his condition. Lord Townsend told me that he put an end to his own life. Though I disbelieve this, I knew he was ridiculed by the courtiers. They laughed at his manners at the levee, at the perpetual quotations of his brother Foster (Foster Hutchinson, brother of governor Hutchinson, was a judge of the supreme court in Massachusetts, searching his pockets for letters to read to the king, and the king's turning away from him with his nose up," &c.

As a judge, he was irreproachable, and evinced great ability. He was a writer of considerable merit, more valuable for his facts than his style. His principal work was a *History of Massachusetts Bay*, in two volumes, with a volume of State Papers, which was brought down to the year 1750. He left a continuation of it in manuscript, which was published in London, in 1828, forming a third volume of the history. His other productions consist of occasional essays, and a pamphlet on Colonial Claims, in 1764. A large number of manuscripts of all kinds concerning the colonies, which he had collected, were unfortunately destroyed during the riot in Boston, when his house was nearly demolished.

HUTTEN, ULRICH VON, was descended from an ancient family, which could boast of many knights and statesmen distinguished in the service of the German emperors. Hutten was born at the family castle of Steckelberg on the Maine, in 1488. In his tenth year, his father placed him at Fulda, in order to educate him for a monk. The monastic school there was one of the most famous in all Germany, and he received an excellent education; but the monastic life corresponded so little with his inclination, that he fled to Erfurt, in 1504, where he became intimately acquainted with several scholars and poets. A pestilence drove him, in the next year, to Cologne, the university in which place was then flourishing. But Rhagius, one of the most learned professors there, having been banished, retired to Frankfurt on the Oder, whither Hutten accompanied him. His patron, Eitelwolf von Stein, assisted him in various ways, during the three years of his residence here. But quiet did not long accord with his restless disposition. He travelled in the north of Germany, although tormented with the loathsome disease, which, making its first appearance at that time, raged like a pesti-

lence, but was not as yet attended with disgrace, and visited Greifswald and Rostock, where he was welcome as a poet and man of talents, and where he supported himself by his labours. In 1511, he went to Wittenberg, where he published a work on versification. From thence he proceeded to Pavia to study law, and, if possible, to conciliate his father. During the time of his residence there, Pavia was taken by the Swiss in the service of Maximilian I., and these troubles compelled him to remove to Bologna, after having been stripped of his property by the soldiers. He was finally compelled, by sheer want, to enter the imperial service, in 1513. The next year, he left the service, and became known throughout Germany. Ulric, duke of Wurtemberg, had murdered a cousin of Hutten, partly from jealousy, partly from hatred, and Hutten gave free course to his indignation in poems, letters, and addresses. He was no less distinguished in the Reuchlinian controversy with the Dominican Hogstraeten in Cologne. Hutten vigorously defended the learned, honest, and persecuted Reuchlin, particularly in satires, and the *Epistola obscurorum Virorum*, in which he had the greatest share, contributed to display the monks in all their nakedness. To please his father, he went again to Italy, in 1515, to take the degree of doctor of laws in Bologna. He first visited Rome, and afterwards went to Bologna; but he could not remain any where long, and soon returned by way of Venice to his country, where he was adorned with the poetic laurel in Augsburg, by the fairest of the German maidens—Constantia, the daughter of Peutingier—and was knighted by Maximilian.

In Italy, Hutten had become acquainted with the monastic life in all its deformity, and was so much the enemy of the clergy, that, by his edition of Laurentius Valla, *De falso credita et ementita Donazione Constantini*, he declared war upon them, and opened the way for Luther. He dedicated the work to pope Leo X., but it is difficult to decide whether this was in ridicule, or from a sincere conviction that this pope was more honest in his opinions than the former popes. In 1518, he entered the service of Albert, archbishop of Mayence, and made several official journeys to Paris. He also accompanied the archbishop to the diet at Augsburg, where Luther held his well known discussion with Cajetan, and Hutten, in a Demosthenic oration, urged the German princes to a war against the Turks; but he was soon wearied with courts, and he took the field, with the Suanbian league, in 1519, against his hereditary enemy, Ulric of Wurtemberg, where he contracted an intimacy with the brave Francis of Sickingen. After the termination of the war, he returned to Mayence, where he received applause from all quarters for his various works against the hierarchy. In order to engage anew in this labour, he retired to the solitude of his paternal castle. Here one work followed another, exhibiting in a strong light the arrogance and corruption of Rome; but, as the objects of his attacks complained to his patron, Albert of Mayence, he lost, eventually, the favour of the latter, but formed publicly a connexion with Luther, and began to write altogether in German, instead of Latin, as he had formerly done. At length the Roman authorities demanded that he should be delivered up to them: attempts were made to assassinate him, and he was not safe, even in the headquarters of Charles V. But his faithful friend, Francis of Sickingen, allowed him an asylum in his castle, whence he issued new salivates to princes and people. Meanwhile, Sickingen became involved in a bloody feud with Richard, archbishop of Treves, which terminated unhappily for the former, and Hutten had to seek another place of

refuge. He hoped to find it in Switzerland, but Erasmus was opposed to him, so that he was obliged to change from one place to another, till finally, overpowered by a new attack of his disease, at the age of thirty-six years, he found, on the island of Ufenau, in the lake of Zurich, Aug. 31, 1523, that repose which had never been his lot on earth, in consequence, partly of his character, partly of his domestic relations, partly his literary labours.

Hutten was one of the boldest and most free-spirited men of his time; a forerunner and promoter of the reformation; an example, an assistant for Luther, with whom he was never personally acquainted, for, although he met him in Augsburg, in 1518, he had then too little respect for a mendicant friar to seek his acquaintance. But he was subsequently impressed with the greatest veneration for him, as he had formerly been for Reuchlin. His principal fault as a writer was a kind of frivolity, which caused him to disregard many circumstances, which, to use the words of Erasmus, should have been treated more tenderly. But his motto—*Jacta alea est*—expressed his principles, which allowed him as little to pause as Luther, who was more favoured by fortune. Injustice, falsehood, hypocrisy, and tyranny filled him with indignation, and he unmasked them with all his power. While all his friends were trembling, his courageous spirit knew no fear. There are forty-five works from his hand, exclusive of several which are not certainly known to be his. After several attempts, a collection of them has been made. It appeared in five volumes (Berlin and Leipzig, 1821—1825): the editor is E. J. H. Munch. The most complete and the latest biography of Hutten appeared in Nuremberg, 1823, from the pen of C. J. Wagenseil of Augsburg.

HUTTON, CHARLES, LL. D., an eminent mathematician, was born at Newcastle-upon-Tyne, Aug. 14, 1737, and his father, who was a viewer of miners, intended to devote him to his own employment. He received a little instruction in the rudiments of the Latin language, and in the elements of the mathematics; but he owed nearly the whole of his subsequent acquirements to his own application. Having received an injury in one of his arms, he was found unfit for his intended occupation, on which the natural bent of his inclinations led him to prepare himself for becoming a mathematical teacher. The destruction of the old bridge at Newcastle having attracted his attention to the subject of the construction and properties of arches, he was led to the production of a small work on the principles of bridges, which laid the foundation of his future fame. He was soon after appointed professor of mathematics at Woolwich college, elected a fellow of the royal society, and, in 1779, received the degree of LL. D. from the university of Edinburgh. In 1785, he published his *Mathematical Tables*, preceded by an introduction, tracing the progress and improvement of logarithms from the date of their discovery. This work has gone through five editions. The next year, doctor Hutton published a quarto volume of *Tracts, Mathematical and Philosophical*, which was not long after followed by his *Elements of Conic Sections*, for the use of the academy at Woolwich. His *Mathematical and Philosophical Dictionary* (2 vols., 8vo), appeared in 1796, of which a new and greatly enlarged edition was published in 1815. In 1798, he gave the world the first edition of his *Course of Mathematics*, in 2 vols., 8vo, to which a third was added in 1811. From 1803 to 1809, he was employed, in conjunction with doctors Pearson and Shaw, in an abridgment of the *Philosophical Transactions*, published in eighteen thick quarto volumes. In 1812, he published another collection of *Tracts*,

on mathematical and philosophical subjects. He died January 27, 1823, in the eighty-sixth year of his age.

HUTTON, JAMES; a natural philosopher, distinguished as the author of a system of geology, which refers the structure of the solid parts of the earth to the action of fire, hence termed the *Plutonian theory*. He was born at Edinburgh, in 1726, and studied in the university under Maclaurin, the celebrated mathematician. He also applied himself to chemistry, and went to Leyden, where he graduated as M. D., in 1749. About 1768, he settled at Edinburgh, where he published numerous works relating to natural philosophy, among which are, *Dissertations on different Subjects in Natural Philosophy* (Edinburgh, 1792, 4to), an *Investigation of the Principles of Knowledge*, and of the *Progress of Reason from Sense to Science and Philosophy* (Edinburgh, 1794, 3 vols., 4to), *Theory of the Earth, with Proofs and Illustrations*, in four parts (Edinburgh, 1795, 2 vols., 8vo). His death took place in 1797. The geological system, or theory of the earth, proposed by this philosopher, excited a warm controversy among men of science, and met with an advocate in the late professor Playfair, who, in 1802, published a work entitled *Illustrations of the Huttonian Theory of the Earth*.

HUUS (*Aenue, dwelling*); a Danish and Norwegian correlative of the German *haus*, and English *house*, appearing in many geographical names.

HUYGENS, CHRISTIAN (or, as it was sometimes written, *Huyghens*), distinguished for his researches and discoveries in the departments of mathematics, physics, and astronomy, son of Constantine Huygens, a poet, was born in 1629, at the Hague. He accompanied Henry, count of Nassau, in 1649, to Holstein and Denmark. He afterwards travelled in France and England, and lived at Paris, from 1666 to 1681, with a pension from the king of France. To him is generally ascribed, on the European continent, the application of the pendulum to clocks (1656), by which he was led to the discovery of evolutes. The English attribute the invention of the pendulum clock to Hooke. Huygens treats of these subjects in his principal work, *Horologium oscillatorium*, &c. (Paris, 1673, fol.), which also contains a complete treatise on the properties of the cycloid, connected with his theory of pendulum clocks and evolutions. This, and other geometrical discoveries, he applied with great success to mechanics. He investigated the laws of the motion of heavy bodies in a given path. He discovered, in 1661, simultaneously with Wallis and Wren, the laws of the communication of motion, by impact, and proposed the theory of oscillatory motion, in which he solved the problem of the centre of oscillation, and the laws of the central forces. To him is, moreover, ascribed the discovery of the principles more fully developed by James Bernoulli, of the preservation of living forces. He was not less distinguished in optics, and he gave a physico-mathematical theory of the motion of light, by which he attempted to explain the strength and liveliness of light. He also acquired a high reputation in astronomy, by establishing many fundamental truths; he examined more minutely, with telescopes improved by himself, in 1655, the form and ring of Saturn, and discovered the four satellites of this planet, &c. His works have appeared in three collections—*Huygenii Opusc. Posthuma* (Leyden, 1707); *Opera varia ed. J. A. s' Gravesande*, with the *Life of Huygens* (Leyden, 1724, 4 parts); and, finally, *Opera reliqua*, &c. (Amsterdam, 1728, 2 vols. 4to). Jurisprudence, which he studied at Leyden, he abandoned from a greater inclination for the mathematical and natural sciences, for the study of which he tra-

velled much. He devoted his life to science, and resided partly in Paris, partly at the Hague. At the latter place he died, in 1695. See his *Life* prefixed to the edition of his works, by s' Gravesande, and in Montucla's *Hist. des Math.*, 2d vol., p. 415.

HUYSUM, JOHN VAN, the most distinguished flower and fruit painter of modern times, was born at Amsterdam, in 1682. He surpassed his predecessors in softness and freshness, in delicacy and vivacity of colour, in fineness of pencilling, in the disposition of light, and in exquisite finish. His father, Justus Huysum, a picture dealer and a painter of moderate merit, at first employed him in all branches of painting; but young Huysum, at a maturer age, felt a decided inclination for the representation of the productions of the vegetable kingdom. He therefore separated from his father, and married about 1706. In landscape painting, he followed the manner of Nicholas Pienmont, a much esteemed painter in Holland. But he reached the highest perfection in flower and fruit pieces. He knew how to penetrate the secrets of nature, to seize the transitory blossom in its most perfect state, and to represent it with enchanting truth and variety of colours. He was the first who had the idea of painting flowers on a white ground. He was so jealous of rivalry, that he permitted no one to see him at work, nor would he take any pupils, except his brother Michael and the daughter of a friend. His flowers have more truth and beauty than his fruits; the drops of dew and insects which he painted on them are like real life. Unhappy domestic circumstances, particularly the levity and prodigality of his wife, and the bad conduct of his son, rendered him melancholy; yet his works show no traces of this turn of mind. He died at Amsterdam, 1749, without leaving a fortune to his three sons, though his pictures sold for 1000 to 1400 florins. His brother Justus was a battle painter, and died at the age of twenty-two years. The third, James, copied his brother's flower and fruit pieces so perfectly, that they brought a very high price. He died in England, in 1740.

HYACINTH. The numerous and splendid varieties of the garden hyacinth (*hyacinthus Orientalis*) have always been general favourites, and in some countries, the fondness for this plant amounts to a complete mania. In Holland, upwards of 2000 varieties have received distinct names, recognised by the different florists, and the price of 1000 florins has been paid for a single plant. (See *Flower-Trade*.) The environs of some of the Dutch towns astonish the traveller, from the gorgeous appearance produced by the vast profusion of these flowers. The wild plant is a native of the Levant, and has a bulbous root, from which rise a few linear lanceolate leaves and a leafless stem, bearing six or eight bell-shaped flowers, of a blue or white colour. The cultivated double varieties have very graceful forms and a remarkable diversity of colour. The natural affinities of this plant place it in the same family with the squill and onion. All the species of hyacinth are natives of Europe.

HYACINTH, in mineralogy. See *Zircon*.

HYACINTHUS; in heathen mythology a son of Amyclas and Diomedes, greatly beloved by Apollo and Zephyrus. He returned the former's love, and Zephyrus, incensed at his coldness and indifference, resolved to punish his rival. As Apollo, who was intrusted with the education of Hyacinthus, once played at quoits with his pupil, Zephyrus blew the quoit, as soon as it was thrown by Apollo, upon the head of Hyacinthus, and he was killed with the blow. Apollo was so disconsolate at the death of Hyacinthus, that he changed his blood into a flower which bore his name, and placed his body among the con-

stellations. The Spartans established yearly festivals in honour of the nephew of their king.

**HYADES.** The Hyades, according to Ovid, were nymphs, daughters of Atlas and Æthra; according to others, daughters of Cadmus or Erectheus. Their number was given differently. They bewailed the death of their brother Hyas, who was torn in pieces by a lioness, with such unceasing anguish, that the gods, moved with compassion, transferred them to the heavens, where they still weep. They form the well known constellation in the head of Taurus. According to the most probable account, these stars derived their name from the Greek word *hyas*, to rain, because rain usually follows their rising and setting. On this account they have received the names of *mournful* (*tristes*) and the *rain-bringing* (Latin, *succulæ*), which circumstances probably gave rise to the above-mentioned fable. Some poets have confounded them with the Pleiades. The chief of the Hyades in the left eye of Taurus, is the bright star called *Aldebaran*, by the Arabs.

**HYÆNA** (*canis*, Lin., *hyæna*, Desm.) This well known and savage genus of quadrupeds is distinguished by having no tuberculous or small teeth behind the carnivorous. Its dental formula is, incisors 1, canine 1, molar 1 = 34. These teeth are well adapted from their great thickness and strength, to break bones. The head of the hyæna is of a middle size, with an elevated forehead; the jaws are shorter, in proportion, than those of dogs, and longer than those of cats; the tongue is furnished with rough papillæ; the eyes are large, and have longitudinal pupils; the ears are long, pricked, very open, and directed forwards. Beneath the tail is a glandulous pouch. Naturalists have described three species of the hyæna.

The common or striped hyæna (*H. vulgaris*), which is a native of Asiatic Turkey, Syria, Abyssinia, &c., is about the size of a large dog, of a brownish gray colour, and marked with transverse bands of dark brown on the body, which become oblique on the flanks and legs. The hair upon the line of the back is much thicker and stronger than on any other part, forming a sort of mane, extending from the nape of the neck to the origin of the tail. This species was well known to the ancients, who entertained many absurd notions respecting it; believing that its neck consisted of but one bone; that it changed its sex every year; that it could imitate the human voice; that it had the power of charming the shepherds, and riveting them to the spot, as the serpent is said to fascinate a bird. Lucan furnishes the Thessalian sorceress with the neck of one of these animals as a potent spell.\* The hyæna generally inhabits caverns and rocky places, prowling about at night to feed on the remains of dead animals, or on whatever living prey it can seize. The common idea, that these animals tear newly buried bodies out of graves, is not inconsistent with their insatiate voracity and the peculiar strength of their claws. The courage of the hyæna is equal to his rapacity. Kämpfer says, that he saw one which had put two lions to flight. At Darfur, a kingdom in the interior of Africa, the hyænas come in herds of six, eight, and often more, to the villages at night, and carry off with them whatever they are able to master. They will kill dogs and asses, even within the enclosure of the houses, and fail not to assemble wherever a dead camel or other animal is thrown; nor are they much alarmed at the sight of men or the report of fire-arms. In these attacks, if one of them should be wounded, his companions instantly tear him in pieces and devour him. (Brown.) A remarkable peculiarity in

this animal is, that when he is first obliged to run, he always appears lame for a considerable distance, and that, in some cases, to such a degree, as to induce a belief that one of his legs is broken; but after running for some time, this halting disappears, and he proceeds on his course very swiftly. (Bruce.) It was formerly supposed that the hyæna was untamable, and this assertion has been copied by most writers on natural history without investigation. But that it can be completely tamed, there is not the shadow of a doubt. The hyæna has lately been domesticated in the Sneeuberg (South Africa), where it is considered as one of the best hunters after game, and as faithful and diligent as any of the common domestic dogs. (Barrow.) A Mr. Trill, in India, had one for many years, which followed him about like a dog. (Heber.) It is, in fact, exceedingly doubtful whether any animal is incapable of subjection to man.

The spotted hyæna (*C. crocuta*, Lin., *H. capensis*, Desm.) has a considerable resemblance to the former species, but is larger, and is marked with numerous round blackish-brown spots instead of stripes, nor is the mane so large. This species inhabits many parts of Africa, but is peculiarly numerous around the cape of Good Hope, where it is much dreaded. One of them entered a negro hut, laid hold of a girl, flung her over its back, held her by one leg in its teeth, and was making off with her, when her screams fortunately brought assistance, and she was rescued. (Bosman.) Those animals act the part of scavengers in South Africa. At the cape, they formerly came down into the town, unmolested by the inhabitants, to devour the filth and offal. Among the savage tribes in this part of Africa, the dead are never buried after a battle, the birds and beasts of prey relieving the living of that trouble; even the bones, except a few of the less manageable parts, finding a sepulchre in the voracious maw of the hyænas. Thunberg informs us, that they are so excessively bold and ravenous, as sometimes to eat the saddle from under the traveller's head, and gnaw the shoes on his feet, while he is sleeping in the open air. In fact, every kind of animal substance is a prize to them, and this gluttony seems a kind provision of nature, to consume those dead and corrupting bodies, which, in warm climates, might otherwise cause disease and death among the inhabitants. The following curious incident is related by Sparmann: One night, at a feast near the cape, a trumpeter, who had become intoxicated, was carried out of doors, in order to cool and sober him. The scent of him attracted a hyæna, which threw him on his back, and dragged him along like a corpse up towards Table mountain. In the mean time the drunken musician revived sufficiently to find the danger of his situation, and to sound the alarm with his trumpet, which fortunately he had not relinquished. The wild beast became alarmed in turn, and fled.

There is another species mentioned by Cuvier (the *H. brunnea*, Thunberg; *H. villosa*, Smith), of which little is known. It differs from the preceding, by having stripes on the legs, the rest of the body being of a dark grayish-brown. It inhabits the south of Africa, and is known there under the name of *sea shore wolf*. The bones of a species of this animal have, of late years, been found in a fossil state in various parts of Europe, but more particularly in England. The scientific world are indebted, in a great measure, to professor Buckland, of Oxford, for the information we have on the subject. This fossil or extinct species (*H. spelæa*), according to Cuvier, was about one third larger than the striped species, with the muzzle, in proportion, much shorter. The teeth resemble those of the spotted species, but are considerably larger.

\* Non dira nodus hyænae defuit. Lib. vi. 672.

**HYALITE.** See *Opal*.

**HYBLA**; a mountain in Sicily, where thyme and odoriferous flowers of all sorts grew in abundance. It is famous for its honey. There is, at the foot of the mountain, a town of the same name. There is also another near mount Ætna, and a third near Catania (*Pauss.*, v. c. 23; *Strab.*, vi. c. 2; *Mela*, ii. c. 7; *Stat.*, xiv. v. 201). A city of Attica bears also the name of Hybla.

**HYCSOS** or **HYK-SHOS** (that is, *shepherd-kings*), a nomadic people from Arabia, which conquered the greater part of Egypt, and held it from about 1700 to 1500 B. C. Their invasions were begun long before their final conquest of Lower and Middle Egypt. They destroyed the temples and cities, carried away women and children into captivity, and, as the Egyptian historians assert, committed the most brutal cruelties. On the eastern frontier of the country, near Pelusium, they built the fortress of Avaris, and founded a kingdom, the capital of which was Memphis. Thebes, however, and some other states, remained distinct governments, but became tributary. The Hyk-shos are supposed to have entered Egypt during the residence of the Israelites in that country, on account of which, the two nations have been confounded with each other. The Pharaoh who was drowned in the Red sea, when pursuing the Israelites, is thought, by some, to have been a Hyk-sho. Manetho (q. v.) mentions a series of their kings, whom he reckons among the Egyptian dynasties. They were probably the builders of the pyramids, who are called in the annals of the priests, *oppressors of the people and enemies of religion*. They were finally conquered by Tethmosis, king of Thebes. Avaris was besieged, and they were obliged to leave the country. On the magnificent ruins of Karnac (q. v.), the events of this war are represented. The Egyptians detested them as the enemies of every thing holy or noble. They are always represented in the bass-reliefs as captives, often lying bound on the ground, serving as footstools, and their images were often painted under the sandals of the Egyptians. If, as is very probable, on the block of black granite in the museum at Turin, which represents three different nations, the Israelites, Negroes, and Hyk-shos are intended, the latter appear in a state of barbarism, wearing a rough skin over their shoulders, with their legs and arms tattooed. This stone is described in one of Champollion's letters to the duke of Blacas. See Spineto's *Lectures on the Elements of Hieroglyphics*, London, 1829.

**HYDASPES**; a river of Asia, flowing by Susa.—Another in India, the boundary of Alexander's conquests in the East. It falls into the Indus.

**HYDE**, EDWARD, earl of Clarendon. See *Clarendon*.

**HYDE**, THOMAS, a celebrated Orientalist, was born in 1636, and went to King's college, Cambridge, at the age of sixteen. There he was recommended to Walton, as capable of assisting him in his great polyglot Bible. Such were his attainments at that time, as to enable him to make a Latin translation of the Persian Pentateuch for that work. In 1658, he went to Oxford, where he was admitted a student of Queen's college, and soon after appointed Hebrew reader to that society. In 1697, he was appointed regius professor of Hebrew, and canon of Christ church, Oxford. He died in 1703. His *Veterum Persarum et Medorum Historia* (third edit., Oxford, 1760) is a valuable work. The *Syntagma Dissert.* (2 vols. 4to, 1767) was edited by doctor Sharpe.

**HYDE PARK** is situated at the west extremity of London. This park derived its name from having been the manor of the Hyde, belonging to the abbey of Westminster. It contains nearly 400 acres, and abounds with fine trees and pleasing scenery. At

the south-east corner of Hyde park, near the entrance from Piccadilly, is a colossal statue of Achilles, executed by Mr Westmacott, and dedicated to the duke of Wellington and his companions in arms. This statue was cast from cannon taken in the battles of Salamanca, Vittoria, Toulouse, and Waterloo, is about eighteen feet high, and stands on a basement of granite, making the whole thirty-six feet above the level of the ground. It was cast from twelve twenty-four pounders, and weighs upwards of thirty tons. The sheet of water called the *Serpentine river*, although in the form of a parallelogram, was made between 1730 and 1733, by order of queen Caroline. It is much frequented in summer for bathing, and during frosts for skating. At the eastern end of it is an artificial waterfall, constructed in 1817. On the south side are the barracks of the life-guards. The park is much frequented as a promenade.

**HYDERABAD**, as a province (*subah*) of the Mogul empire containing forty-two districts (*circars*), and upwards of 400 townships (*perganahs*), comprehending nearly the whole territory between the Godavery and the Krishna, has been much reduced by the diminution of the Mussulman power in India, but still comprehends the territories of the most powerful Mohammedan prince, the nizâm of the Deccan. It is now divided into sixteen districts. Nearly the whole country is parcelled out into feudal lordships, the possessors of which are bound to maintain an armed force. The soil is fertile, but agriculture and commerce are equally discouraged by the badness of the government. A small quantity of muslins, salt, and opium are almost the only articles of commerce. On the death of Aureng-Zebe, this country, which had formed a province of his empire, was taken possession of (1717) by his viceroy, who still preserved the title of *nizâm* or minister. His successors, alarmed by the growing power of the Mahrattas, who had already seized a valuable part of their territory, formed treaties with the British (1798 and 1800), by which it was agreed that a British force should be stationed in the country, and that all the foreign affairs of the nizâm should be managed by the English government.

**HYDERABAD**, the capital, is in 17° 15' N. lat.; 78° 35' E. lon. It is about four miles long and three broad, and is surrounded by a stone wall. Its streets are narrow, crooked, ill-paved, formed by rows of houses of one story. The palace and some of the mosques are the only remarkable buildings, but the tank is worthy of notice; it is nearly seventeen miles in circumference, and covers about 10,000 acres. It is filled by a canal from the river, and is formed by an imbankment, consisting chiefly of granite, 3350 feet long and fifty feet high, which closes the open end of a valley, surrounded on the other three sides by mountains. It was finished in 1812. The population is 200,000.

**HYDER ALLY KHAN**; an Asiatic prince, who rose by his talents to sovereign power, and was a formidable enemy to the English in Hindostan, in the latter part of the last century. He was born at Dinavelli, in the Mysore, and after some military service under his father, a petty chief of the country, he joined his brother in an alliance with France, and introduced European discipline among his troops. He became general-in-chief of the forces of Cinoas, who then reigned at Seringapatam as a vassal of the Great Mogul; and having quarrelled with the grand vizier of his master, he marched against the capital, and obliged Cinoas not only to deliver the vizier into his power, but also to appoint him regent. He subsequently assumed the sovereignty himself; and having deposed the royal family, he founded the Mohammedan kingdom of Mysore, in 1760. He so

greatly extended his dominions, that, in 1766, they contained 70,000 square miles, and afforded an immense revenue. His reign was passed in wars with the English and with the Mahrattas, the former of which powers excited his peculiar jealousy. A treaty which he made with the East India company, in 1769, was violated in 1780, and he was opposed with success in the field by the English general, Sir Eyre Coote. The Mahrattas joining in a league against him, he carried on a disadvantageous war, during the continuance of which he died, in 1782. For an account of the subsequent fate of his empire, see *Tippoo Saib*.

HYDRA; in fabulous history, a celebrated monster, which infested the neighbourhood of the lake Lerna in the Peloponnesus. It was the fruit of Echidna's union with Typhon. It had a hundred heads according to Diodorus, fifty according to Simoniades, and nine according to Apollodorus, Hyginus, &c. The central head was immortal. As soon as one of those heads was cut off, two immediately grew up, if the wound was not stopped by fire. It was one of the labours of Hercules to destroy this dreadful monster, and this he easily effected with the assistance of Iolaus, who applied a burning iron to the wounds as soon as one head was cut off. The central head the conqueror buried in the earth, and covered with a piece of rock. While Hercules was destroying the hydra, Juno, jealous of his glory, sent a sea-crab to bite his foot. This new enemy was soon despatched, and Juno, unable to succeed in her attempts to lessen the fame of Hercules, placed the crab among the constellations, where it is now called the *Cancer*. The conqueror dipped his arrows in the gall of the hydra. From that circumstance all the wounds which he gave proved incurable and mortal. Some writers consider this fable as a symbolical representation of the clearing and draining of the Peloponnesus by the first authors of civilisation.

HYDRA, the centre of the Greek maritime trade, and the palladium of Greek independence, with the neighbouring Spemzia, is situated south-east of the Peloponnesus, between two and three leagues from the coast, and is guarded by steep rocks and batteries from the attacks of an enemy; so that vessels in the port are in no danger but from fire-ships. Spemzia, on the contrary, is unprotected, and its inhabitants at the approach of an enemy, flee for shelter to Hydra. The two islands together contain about eighty-five square miles and 40,000 inhabitants, although without springs, herds, or agriculture. They subsist by navigation and trade. The city of Hydra, containing 30,000 inhabitants, rises like an amphitheatre over the harbour. The houses are very beautiful, and adorned with modern works of art in marble. In the interior, they are very neat and tasteful. A natural grace shows itself even in the dress of the sailors. The ladies live very retired, in the bosom of their families. The first inhabitants of Hydra and Spemzia were of Albanian descent. They differ in their Arnaout dialect, as well as in their character, dress, and manners, from the Romaics or modern Greeks. When the Russians, in the war of 1774, evacuated the Morea, many of the Peloponnesians fled with their property from the vengeance of the Turks to the rocks of Hydra. They now build greater vessels, and undertook more distant voyages, especially since France, in consequence of the war of 1792, was obliged to give up its trade to the Levant. Three modern Argonauts were seen in every harbour of Italy, France, Spain, the Baltic, and even America. In Marseilles, they exchanged the Greek corn for the cloths and silks of Lyons. As bold as they were dexterous, they escaped the British cruisers, and safely entered blockaded harbours, and gained

large profits in this way; so that they were enabled, by the extension of their trade, to establish mercantile houses in the first cities of Europe, before 1810. They equipped their vessels with cannon to secure them against the Algerine corsairs. Accustomed from youth to great activity, to moderation, and the dangers of a sea life, the Hydriots and the other islanders of the Archipelago are the boldest and the most active sailors in the Mediterranean. Commerce has not merely filled their purses; it has also enlightened their minds. Besides the common schools, Hydra has erected, within thirty years, an institution for the cultivation of classical literature, and the Italian and French languages. The rich Hydriots, the Sciots, and others, encouraged the translation and publication of books in foreign languages. They sent their sons to the best schools in Germany, France, and Italy. Thus they became acquainted with the sciences, and acquired a taste for the arts; their manners were refined, and they were enabled to establish, on their return, good seminaries of learning. The late war exhausted their wealth, and caused a total stagnation of their trade. Scarcely were the magistrates able to defray the expenses of the sailors and vessels. On this account, they have, in times of danger, contemplated leaving their country, taking with them their families and property. The restoration of peace, we trust, will restore their ancient prosperity.

HYDRANGEA; a genus of plants, including three or four shrubs, having somewhat of the general appearance of the gelder-rose or viburnum, but differing in the structure of the flowers. All the species are, in their wild state, exclusively confined to the United States of America, but they are frequently cultivated in the European gardens, for ornament. The *H. vulgaris* grows on the Alleghanies, and in other parts of the Union, but not north of Philadelphia, in the Atlantic states. The *H. nivea*, a more ornamental shrub than the preceding, and differing by the white inferior surface of the leaves, and the large size of the marginal flowers, seems to be more exclusively confined to the region about the southern portion of the Alleghanies, extending, however, as far north as Pennsylvania. The *H. quercifolia*, distinguished by its lobate leaves, inhabits the country bordering on the gulf of Mexico, and is not unfrequently cultivated in our own gardens. The *Aortensis* or Japan rose, a plant closely allied to the preceding genus, and sometimes united with it by some authors, is more frequent with us, and has very commonly usurped the name of *Hydrangea*. This plant is a general favourite in China and Japan, the countries from which it was originally brought; and, indeed, the fine corymbs of large rose-coloured flowers, which retain their freshness a long time, and succeed each other throughout the whole season, added to the ease of cultivation, afford well founded claims for distinction. The fruit is yet unknown, the large flowers, so much resembling those of the snow-ball tree, being constantly barren.

HYDRAULICON (*water-organ*), in music; an instrument acted upon by water, the invention of which is said to be of higher antiquity than that of the wind organ.

HYDRODYNAMICS treats of the state and forces of liquids, at rest or in motion. The name is derived from *ὑδρ*, water, and *δυναμις*, force. It is divided into hydrostatics and hydraulics.

*Hydrostatics* (from *ὑδρ*, water, and *στασις*, the science of bodies at rest) is the science which treats of the weight, pressure, and equilibrium of liquid fluids. The particles in liquids are freely movable among each other, so as to yield to the least disturbing force; but though it was formerly believed that the liquid fluids are incompressible, recent experiments have shown that they may be

instantly condensed by pressure. The fundamental truth, on which the whole science of hydrostatics rests, is equality of pressure. All the particles of fluids are connected together, that they press equally in every direction, and are continually pressed upon; each particle presses equally on all the particles that surround it, and is equally pressed upon by them; it equally presses upon the solid bodies which it touches, and is equally pressed by those bodies. From this, and from their gravity, it follows, that when a fluid is at rest, and left to itself, all its parts rise or fall so as to settle at the same level, no part standing above or sinking below the rest. Hence, if we pour water or any other liquid into a tube bent like the letter U, it will stand at the same height in both limbs, whether they are of the same diameter or not, and thus a portion of the liquid, however small, will resist the pressure of a portion however large, and balance it. In a common tea-kettle, for instance, water poured into the body of the vessel will rise to the same level in the nose as in the vessel; and if poured into the nose, the same will also be true, and the small column of water in the nose balances the whole column in the body of the vessel, and will continue to do so, however large the one, and however small the other may be. From this fact two important conclusions follow, derived both from reasoning and from daily experience. The one is, that water, though, when unconfined, it can never rise above its level at any point, and can never move upwards, will, on being confined in close channels, rise to the height from which it came, that is, as high as its source; and upon this principle depend all the useful contrivances for conveying water by pipes, in a way far more easy, cheap, and effectual than by those vast buildings, called *aqueducts*, by which the ancients carried their supplies of water in artificial rivers over arches for many miles. In this case, the stream must have been running down all the way, and consequently a fountain fed from it at its termination, could not furnish the water at the same height as its source. The other conclusion is not less true, but far more extraordinary, and, indeed, startling to belief, if we did not consider the reasoning upon which it is founded; it is that the pressure of the water upon any object against which it comes, is not in proportion to the body or bulk of the water, but only to the size of the surface, on or against which it presses, and its own height above that surface. Thus, in a tunnel-shaped vessel, the pressure on the bottom is not proportioned to the whole body of water in the vessel, but only to a column of the fluid equal in diameter to the bottom. The general rule for estimating the pressure of any fluid, is to multiply the height of the fluid by the extent of the surface on which it stands. If any portion of the fluid is supported by a tube above the remainder, the pressure on the bottom of the vessel will be the same as if the water was throughout at the same height as that in the tube, so that the height of the tube is properly multiplied by the extent of the bottom of the vessel, to determine the whole pressure. This principle of equal pressure has been called the *Hydrostatic paradox*, though there is nothing in reality more paradoxical in it than that one pound at the long end of a lever should balance ten pounds at the short end; it is, indeed, but another means, like the contrivances called *mechanical powers*, of balancing different immensities of force by applying them to parts of an apparatus which move with different velocities. This law of pressure is rendered very striking in the experiment of bursting a strong cask by the action of a few ounces of water. Suppose a cask already filled with water, and let a long tube be screwed tightly into its top, which tube will contain only a few ounces of water; by filling this tube the cask will

be burst. The explanation of the experiment is this; if the tube have an area of a fortieth of an inch, and contain half a pound of water, this will produce a pressure of half a pound upon every fortieth of an inch over all the interior of the cask. The same effect is produced in what is called the *hydrostatic bellows*. The tube is made to communicate with an apparatus constructed like a common bellows, but without a valve. If the tube holds an ounce of water, and has an area equal only to one thousandth of that of the top board of the bellows, an ounce of water in the tube will balance weights of a thousand ounces resting on the bellows. The hydrostatic or hydraulic press of Mr Bramah, (See *Bramah's press*), is constructed on this principle; a prodigious force is thus obtained with great ease, and in a small compass, so that, with a machine the size of a common teapot, a bar of iron may be as easily cut as a slip of paste-board. A small forcing pump takes the place of the tube in the instrument above described, and a pump barrel and piston is substituted for the bellows; water is then driven from the small pump into the large barrel under the piston, and the piston is thus pressed against the object to be operated upon. If the small pump have one thousandth of the area of the large barrel, and the force of 500 pounds be applied to its piston by its lever handle, the great piston will rise with a force equal to one thousand times 500 pounds, or more than two hundred tons. The uses to which this power may be applied, are of great variety and extent, but this branch of art seems to be yet in its infancy. Upon the tendency of all the parts of fluids to dispose themselves in a plain or level surface, depends the making of *levelling instruments*, or instruments for ascertaining whether any surface is level, or any line horizontal; for finding what point is on the same level with any given point, and how much any point is above or below the level of any other point.

We have thus far spoken of the pressure of liquids upon a horizontal or level surface, in which case it is only necessary to multiply the height of the fluid by the extent of the surface, and the weight of the bulk is equal to the pressure upon the surface. But if the surface is not horizontal, a different rule must be applied; for then the pressure is equal to the weight of the bulk, found by multiplying the extent of the surface into the depth of the centre of gravity of the surface. In this manner we can find the pressure upon a dam; we must take half the depth of the water, and multiply it by the superficial extent of the dam; this gives the bulk of water whose weight is the pressure on the dam. The pressure against the upright sides of a cylinder filled with water, may be found by multiplying the curve surface under water by the depth of its centre of gravity, which is half the depth of the water. The increase of pressure in proportion to the depth of the fluid, shows the necessity of making the sides of pipes or masonry, in which fluids are to be contained, stronger in proportion to their depth. It is therefore needless to make them equally thick and strong from the top downwards. If they are thick enough for the great pressure below, they will be thicker than is required for the smaller pressure above. The same is true in regard to flood-gates, dams, and banks.

When a solid body is plunged in any liquid, it must displace a quantity of that liquid exactly equal to its own bulk. Hence by measuring the bulk of the liquid so displaced, we can ascertain, precisely the bulk of the body; for the liquid can be put into any shape, as that of cubic feet or inches, by being poured into a vessel of that shape divided into equal parts. This is the easiest way of measuring the solid contents of irregular bodies, when a body is plunged into a

liquid, if it be of the same weight as the liquid, it will remain in whatever part of the fluid it is placed; if it be heavier, it will sink to the bottom; if lighter, it will rise to the top. If any body, therefore, be weighed in the air, and then weighed in a liquid, it will lose as much in weight as an equal bulk of the liquid weighs. In this manner we determine the relative weights of all bodies, or the proportion which they bear to each other in weight, which is called their *specific gravity*. (q. v.) Suppose a mass of gold, for instance, to have a certain weight in the air; it would lose, on being weighed in water, about a nineteenth of its weight; that is, the gold would be nineteen times heavier than water. The instrument used for this purpose is called the *hydrostatic balance*, (See *Balance*) and affords the easiest and most accurate method of comparing all substances, whether solid or fluid. This operation may be performed with substances lighter than water, by attaching them to a stiff pin, fastened to the bottom of the scale, or by suspending some heavy substance of a known weight. The same principle also enables us to ascertain the specific gravities of different fluids; for, if the same substance be weighed in two fluids, the weight which it loses in each is as the specific gravity of that fluid. (See *Hydrometer*.)

Mr Thom of Rothsay has employed the principle of floating bodies in the regulation of the height of water in mill dams. The accompanying wood cut shows a section of one of his contrivances for this purpose, called a self-regulating sluice.

**The water sluice.** This sluice, when placed upon any river, canal, reservoir, or collection of water, prevents the water within the embankment from rising above the height we choose to assign to it; for whenever it rises to that height, the sluice opens and passes the extra water; and whenever that extra water is passed, it shuts again; so that whilst it saves the banks at all times from damage by overflow, it never wastes any water we wish to retain. A C B L, part of a canal, river, stream, or collection of water. B C, high water mark, or the greatest height to which the water is to be allowed to rise. B D, a sluice, or folding dam, which turns on pivots at D. E F, a hollow cylinder, having a small aperture in its bottom, to which is joined F L, a small pipe always open. I I I I, small holes in cylinder E F, on the line of high water mark. G H, another cylinder, waterproof, that moves up and down freely within cylinder E F; and the weight of which keeps the sluice B D shut by its connexion with B K H, a chain fixed to cylinder G H at H, thence passing over pulley K, and having its other end fixed to sluice B D at B. When the water in the canal, river, or pond, rises to the line B C, it passes into cylinder E F, at the small holes I I I I; and this lessens the weight of cylinder G H so much that the pressure of the water in front of sluice B D throws it open. When the water subsides, so as not to enter these holes, the cylinder is emptied by the tube F L; and then the weight of cylinder G H shuts the sluice as before. The dimensions and weight of this cylinder must of course correspond with the weight of the column of water pressing upon sluice B D. This sluice is here represented with the pivots on which it turns at its under edge, but they may be

placed either at the upper or under edge as circumstances render advisable. The upper edge is also here represented on a level with high water mark, but if necessary, it may be placed anywhere between that and the bottom of the pond, or aqueduct, or right below, as on an aqueduct bridge, or similar situation. The cylinders may also be placed on the outside of the dam or embankment, by having a pipe to communicate between them and the water within, but in whatever situation the sluice or cylinders may be placed, the pipe that communicates between the cylinders and the water within the embankment must always have its opening there exactly at the level of high water mark, or at the greatest height to which the water therein is to be permitted to rise. On this principle a self-acting dam may be raised in any river or stream, up to high water mark, by which means a considerable reservoir will be obtained, whilst during floods the dam will fold down, and no new ground be overflowed. In lawns, or pleasure grounds, through which streams or rivulets flow, these sluices might be applied to advantage; for by placing one on the bank of each pond, the water within would always be kept at the same height, whether the weather were wet or dry; and hence flowers or shrubs might be planted close to the water's edge, or in it, (as best suits their respective habits,) and their position with regard to water, would always be the same.

The principles of buoyancy are very ingeniously applied in Mr Farey's *self-acting flood-gate*. In the case of common sluices to a mill-dam, when a sudden flood occurs, unless the miller gets up in the night to open the gate or gates, the neighbouring lands may become inundated; and, on the contrary, unless he be present to shut up when the flood subsides, the mill-dam may be emptied and the water lost when he would need the next day. To prevent either of these occurrences, Mr JOHN FAREY, whose talent and ingenuity are well known, has proposed a *self-acting flood gate*, the following description of which has been given in the *Mechanics' Weekly Journal*.

A A represents a vertical section of a gate poised upon a horizontal axis passing rather above the centre of pressure of the gate, so as to give it a tendency to shut close. a a is a lever, fixed perpendicular to the gate, and connected by an iron rod with a cask, b, floating upon the surface of the water, when it rises to the line, b, n, which is assumed as a level of the wear or mill-dam, a, c, x, r, in which the flood-gate is placed; by this arrangement, it will be seen that when the water rises above the dam, it floats the cask, opens the gate, and allows the water to escape until its surface subsides to the proper level at a, r, the cask now acts by its weight, when unsupported by the water, to close the gate and prevent leakage. The gate should be fitted into a frame of timber, m, n, which is set in the masonry of the dam. The upper beam, n, of the frame being just level with the crown of the dam, so that the water runs over the top of the gate at the same time that it passes through it, to prevent the current disturbing the cask, it is cus-

acted by a small rod,  $e$ , at each end, to the upper beam,  $u$ , of the frame, and jointed in such a manner as to admit of motion in a vertical direction.

If a single drop of water, or any liquid of a like degree of fluidity, be pressed upon a solid surface, it will wet that surface, and adhere to it, instead of keeping together and running off. This shows that parts of the liquid are more attracted by the parts of the solids than by one another. In the same manner, round the glass in which a liquid is contained, its surface will be seen to be higher than in the centre. If the vessel be less than the twentieth part of an inch in diameter, the liquid will rise in it the higher in proportion to the smallness of the diameter. This is called *capillary attraction*, and tubes of this kind are called *capillary tubes*. See *Capillary Tubes*; see also *Pumps, Siphons, Springs*.

*Hydraulics* (from ὑδρῆς, water, and αὐλός, a pipe, referring to the movement of water in certain musical instruments used by the Greeks); that branch of hydrodynamics which has for its object the investigation of the motions of liquids, the means by which they are produced, the laws by which they are regulated, and the force or effect which they exert against themselves or against solid bodies. This subject naturally divides itself into three heads: 1. the effects which take place in the natural flowing of fluids through the various ducts or channels which convey them; 2. the artificial means of producing motion in fluids, and destroying their natural equilibrium by means of pumps and various hydraulic engines and machines; and 3. the force and power which may be derived from fluids in motion, whether that motion be produced naturally or artificially.

The particles of fluids are found to flow over or amongst each other with less friction than over solid substances; and as each particle is under the influence of gravitation, it follows that no quantity of homogeneous fluid can be in a state of rest, unless every part of its surface is on a level, that is, not a level plane, but so far convex as that every part of the surface may be equally distant from the centre of the earth. As the particles of all liquids gravitate, any vessel containing a liquid will be drawn towards the earth with a power equivalent to the weight it contains, and if the quantity of the fluid be doubled, tripled, &c., the gravitating influence will be doubled, tripled, &c. The pressure of fluids is, therefore, simply as their heights,—a circumstance of great importance in the construction of pumps and engines for raising water. As liquids gravitate independently, if a hole be made in the bottom of the vessel, the liquid will flow out, those particles directly over the hole being discharged first. Their motion causes a momentary vacuum, into which the particles tend to flow from all directions, and thus the whole mass of the water, and not merely the perpendicular column above the orifice, is set in motion. If the liquid falls perpendicularly, its descent will be accelerated in the same manner as that of falling solid bodies. (See *Mechanics*.) When water flows in a current, as in rivers, it is in consequence of the inclination of the channel, and its motion is referable to that of solids descending an inclined plane; but, from want of cohesion among its particles, the motions are more irregular than those of solids, and involve some difficult questions. The friction between a solid and the surface on which it moves can be accurately ascertained; but this is not the case with liquids, one part of which may be moving rapidly and another slowly, while another is stationary. This is observable in rivers and pipes, where the water in the centre moves with greater rapidity than at the sides, so that a pipe does not discharge as much water in a given time, in proportion to its magnitude, as theoretical calcu-

lation would lead us to suppose. As water, in descending, follows the same laws as other falling bodies, its motion will be accelerated; in rivers, therefore, the velocity and quantity discharged at different depths would be as the square roots of those depths, did not the friction against the bottom check the rapidity of the flow. The same law applies to the spouting of water through jets or adjutages. Thus, if a hole be made in the side of a vessel of water, the water at this orifice, which before was only pressed by the simple weight of the perpendicular column above it, will be pressed by the same force as if the water were a solid body descending from the surface to the orifice; that is, as the square root of the distance of those two points; and, in the same way, water issuing from any other orifices, will run in quantities and velocities proportionate to the square root of their depths below the surface. Now, the quantity of water spouting from any hole in a given time, must be as the velocity with which it flows: if, therefore, a hole  $A$  be four times as deep below the surface as a hole  $B$ , it follows that  $A$  will discharge twice as much water in a given time as  $B$ , because two is the square root of four. A hole in the centre of such a column of water, will project the water to the greatest horizontal distance (or range), which will be equal to twice the length of the column of which the orifice is the centre. In like manner, two jets of water, spouting from holes at equal distances above and below the central orifice, will be thrown equal horizontal distances. The path of the spouting liquid will always be a parabola, because it is impelled by two forces, the one horizontal, and the other (gravitation) perpendicular.

To prove this by experiment, let two pipes of equal size,  $m$  and  $n$ , be fixed into the side of the vessel  $A$ , but so that the pipe  $n$  is placed four

times deeper below the surface  $c$  than the pipe  $m$ . (In this case the orifices  $f C g$  are supposed to be closed.) If the surface of the water in the vessel be kept at the same height by a constant supply being poured in, and if two vessels, one of which would hold a pint, be placed under the pipe  $m$ , and the other which would contain a quart under the pipe  $n$ , both vessels will be filled in the same time from their respective pipes. Wherefore the quantities of water passing through equal holes in the same time, are as the square roots of their depths. The horizontal distance to which a fluid will spout from a hole made in the side of an upright vessel may be determined in the following manner. Let the vessel  $A$  be filled with water to the height of the surface, and let  $d k a$  be a horizontal plane upon which the jets fall; on  $c d$ , as a diameter describe a semicircle  $c h d$ , whose centre  $C$  shall be the central height of the column of fluid in the reservoir  $A$ ; then if holes be made in the reservoir at the points  $f C g$ , and lines drawn from them to the semicircle perpendicular to the diameter of the semicircle, or the side of the vessel as at  $f b, C h$ , and  $g i$ ; the distance to which water will spout from the holes  $f C g$ , will be proportionate to the length

of line which cuts the semicircle. As  $C$  is the longest line which can be drawn within the semicircle, the water spouting from  $C$  will reach the greatest horizontal distance  $a$ , and that range, if in vacuo, would be equal to twice the length of line drawn from the point of discharge to the semicircle. Though water will rise in pipes as high as the surface of the head from which it is supplied; yet in perpendicular jets it can never rise so high, because of the resistance of the air, and the friction of the adjutage. The best kind of adjutage is the end of the tube covered with a thin plate, in which is made a smooth hole much less than the bore of the tube. In such an adjutage the water will ascend in a regular shape, and find little friction in passing through the thin plate.

The second division of the subject, mentioned in the beginning of this article, is of the greatest practical utility, as embracing an account of the various pumps and machines which have been employed to raise water; and numerous as these may appear, it will be found that they may all be comprehended under four general heads: 1. those machines in which water is lifted in vessels by the application of some mechanical force to them. The earlier hydraulic machines were constructed on this principle, which is the simplest; such are the Persian wheel, consisting of upright buckets attached to the rim of a wheel, moving in a reservoir of water; the buckets are filled at bottom, as they pass through the water, and emptied at top, so that the water is raised a height equal to the diameter of the wheel. The wheel may be turned by living power, or, if in running water, by fastening float boards to the circumference. A modification, and decided improvement on the Persian wheel has been long in use in Scotland. This wheel was the invention of Mr George Mickle, an ingenious millwright of Alloa, in Clackmannanshire. (See *Persian Wheel*.) The Archimedian screw, the bucket-engine or chain-pump, and the rope-pump of Vera, are modifications of the same principle.

The *Chain Pump* is shown in the annexed figure: it usually consists of a succession of long links of metal rods, revolving like an endless rope over two wheels  $e$   $f$ , one of which,  $f$ , must be under water. On this chain, between each joint, is fixed a flat piece of wood or metal,  $d$   $d$   $d$ , usually square, which is supported and kept in its place by the projecting arms of the wheels  $f$  and  $e$ , though at the same time they are permitted to turn with the same freedom as the chain;—the wheel  $e$  is turned by a winch, which causes the whole chain to move; one side of it passing upwards, while the other side is continually descending in the same direction. The ascending side of the chain is made to pass through a box or pipe, one end of which is immersed in the water, the other end nearly reaching the upper wheel; this box corresponds in shape with the size of the plates which fit pretty closely, and form the pump. The succession of plates passing upward through the trunk, forms a succession of cavities which are filled with water, and are constantly discharged at the top. From the formation of this pump it will only work in deep water, and conse-

quently cannot drain a reservoir to the bottom; but it has the advantage of not becoming choked with sand or weeds; and though some of its advantages may be lost by the plates not fitting closely to the trunk, and thereby allowing some of the water to drain out, yet as an upper chamber can only leak into one below, if the motion of the machinery be very rapid, it cannot lose any considerable quantity of water. It is for these reasons frequently used in draining the water from the foundations of bridges, docks, and other large works. If the top and bottom wheels,  $e$   $f$ , of this machine be retained, while the tube or trunk is taken away, and a number of small boxes or buckets be attached to the chain instead of the plates  $d$   $d$   $d$ , the machine then becomes a *bucket engine*, which is but another form of the Persian wheel already described. A pump on this principle is used in ships, and is called a *Chain pump*.

2. The next class of machines are those in which the water is raised by the pressure of the atmosphere, and comprises all those machines to which the name of *pump* is more particularly applied. These act entirely by removing the pressure of the atmosphere from the surface of the water, which may thus be raised to the height of about thirty-two feet. (See *Atmosphere Air*.) Whenever it becomes necessary to raise water to greater heights, the third class of machines, or those which act by compression on the water, either immediately or by the intervention of condensed air, are employed. All pumps of this description are called *forcing-pumps*. (See *Pump*.) Although atmospheric pressure is not necessary in the construction of forcing-pumps, it is, in most cases, resorted to for raising the water, in the first place, into the body of the pump, where the forcing action takes place. In machines of this kind, the water may be raised to any height.

The common *suction pump* consists of a hollow cylinder  $A$ , of wood or metal, which contains a piston  $B$ , stuffed so as to move up or down in the cylinder easily, and yet be air tight: to this piston there is attached a rod which will reach at least to the top of the cylinder when the piston is at the bottom. In the piston there is a valve which opens upwards, and at the bottom of the cylinder there is another valve  $C$  also rising upwards, and which covers the orifice of a tube fixed to the bottom of the cylinder, and reaching to the well from whence the water is to be drawn. This tube is commonly called the *suction tube*, and the cylinder, the *body* of the pump. When the piston is at the bottom of the cylinder, there can be no air, or at least very little between it and the valve  $C$ , for as the piston was pushed down, the valve in it would allow the air to escape instead of being condensed, and when it is drawn up, the pressure of the air would shut the valve, and there would be a vacuum produced in the body of the cylinder when the piston arrived at the top. But the air in the cylinder being very much rarefied, the pressure of the valve  $C$  on the water at the bottom will be greatly less than that of the external atmosphere on the surface of the water in the well; therefore, the water will be pressed up the pump to a height not exceeding thirty-two feet. As the valves shut downwards, the water is prevented from returning, and the same operation being repeated, the water may be raised to any height, not exceeding the above limit in any quantity.

The quantity of water discharged in a given time, is determined by considering that at each stroke of the piston a quantity is discharged equal to a cylin-

der whose base is the area of a cross section of the body of the pump, and height the play of the piston. Thus, if the diameter of the cylinder of the pump be 4 inches, and the play of the piston 3 feet, then, by mensuration, we have to find the content of a cylinder 4 inches diameter, and 3 feet high—now, 4 inches is the 1 of a foot, or  $\cdot 333$ , hence,  $\cdot 333 \times \cdot 7854 = \cdot 110999 \times \cdot 7854 = \cdot 08796$  = the area of the cross section of the cylinder in square feet; hence,  $\cdot 08796 \times 3 = \cdot 2639$  = the content of the cylinder in cubic feet = the quantity of cubic feet of water discharged by one stroke of the piston. Now, a cubic foot of water weighs about 63.5 lbs. avoirdupois, wherefore,  $\cdot 2639 \times 63.5 = 16.756$  lbs. avoirdupois and an imperial gallon is equal to 10 lbs. of water; whence, dividing the above number 16.756 by 10, we get the number of ale gallons = 1.6756. The piston, throughout its ascent, has to overcome a resistance equal to the weight of a column of water, having the same base as the area of the piston, and a height equal to the height of the water in the body of the pump above the water in the well.

**The lifting pump.** This pump like the suction pump has two valves and a piston, both opening upwards; but the valve in the cylinder instead of being placed at the bottom of the cylinder is placed in the body of it, and at the height where the water is intended to be delivered. The bottom of the pump is thrust into the well a considerable way, and if the piston be supposed to be at the bottom, it is plain, that as its valve opens upwards, there will be no obstruction to the water rising in the cylinder to the height which it is in the well; for, by the principles of hydrostatics, water will always endeavour to come to a level. Now when the piston is drawn up, the valve in it will shut, and the water in the cylinder will be lifted up; the valve in the barrel will be opened and the water will pass through it, and cannot return as the valve opens upwards;—another stroke of the piston repeats the same process, and in this way the water is raised from the well: but the height to which it may be raised is not in this as in the suction pump limited to thirty-two feet. To ascertain the force necessary to work this pump, we are to consider that the piston lifts a column of water whose base is the area of the piston, and height the distance between the level of the water in the well and the spout, at which the water is delivered.

**The forcing pump** remains to be considered. The piston of this pump has no valve, but there is a valve at the bottom of the cylinder the same as seen at A. In the side of the cylinder, and immediately above the valve B, there is another valve A opening outwards into a tube, which is bent upwards to the height H at which the water is to be delivered. When the piston is raised, the valve in the bottom of the pump opens, and a vacuum being produced, the water is pressed up into the pump on the principle of the sucking pump. But when the piston is pressed down, the valve A at the bottom shuts, and the valve B at the side which leads into the ejection pipe opens, and the water is forced up the tube. When the piston is raised again the valve B shuts, and the valve A opens. The same process is repeated, and the water is thrown out at every descent of the piston, the discharge therefore is not constant. It is frequently required that the discharge from the pump should be continuous, and this is effected by fixing to the top of the eduction

pipe an air vessel. This air vessel consists of a box AB, in the bottom of which there is a valve C opening upwards into the box. This valve covers the top of the eduction pipe D. A tube, E, is fastened into the top of the box, which reaches nearly to the bottom of the box, it rises out of the box, and is furnished with a stop cock. If the stop cock be shut, and the water be sent by the action of the pump into the air vessel, it cannot return because of the shutting of the valve at the bottom of the box; and because of the space occupied by the water, the air in the box is condensed, and will consequently exert a proportionate pressure on the water in the air vessel, and force it higher up the tube E.

4. The fourth class of hydraulic machines for raising water, consists of such engines as act either by the weight of a portion of the water which they have to raise, or of any other water that can be used for such purpose, or by its centrifugal force, momentum, or other natural powers; and this class, therefore, includes some very beautiful and truly philosophical contrivances, too numerous for us to describe. The Hungarian machine, the centrifugal pump, and the water-ram, are among the number.

The large pipe AB called the body of the ram, passes through the side of the reservoir PQ, from which the fall of water is obtained. It has a trumpet mouth at one end A, and at the other end an opening HH, which can be closed by valves C or D. When these valves are open, the water will issue at HH with a velocity due to the height AP; but when the internal valve C is closed, as in the figure, the water is prevented from issuing. When the valve C opens, it descends into the position shown by the dotted lines GG, being guided between three or four stems *g g*, which have hooks at the lower ends for supporting the valves. In this case the water has a free passage between these stems, and the width of the passage can be increased or diminished by the screws with

which the stems are fixed. The valve C is made of metal, and has a hollow cup or dish of metal attached to its lower surface. The seat HH of the valve is wider than the diameter of the pipe AB. It consists of a short cylinder or pipe screwed by its flanch *h h* into the opening of the upper surface of the head R of the ram; and the cylinder is so formed as to have an inverted cup or annular space *i i* round the upper part of it for containing air, which cannot escape when it is compressed by the water. A small pipe *k l*, leading from this annular space to the open air, is furnished with small valves, *k, l*, one of which, *k*, opens inwards to admit the air into *i, i*, but to prevent its return, while the other valve, *l*, admits a certain quantity of air, and then shuts and prevents any farther entrance. The valve D is exactly the same as C, only it descends as in the figure when it shuts, and rises when it opens. The upper part

of the head of the ram at E is made flat, and has several valves which allow the water to pass freely from the pipe AB, but prevent its return. On each side of the head of the ram, at the part opposite to these valves is a hollow enlargement, shown by the dotted lines K, forming a circular basin, through the centre of which the pipe ABR passes. The pipe is here made flat instead of circular, for forming the seats of the valves, and the basin KK is covered with an air vessel FF. This air vessel communicates all round the pipe B, with the basin KK, and with the vertical pipe M. The machine being thus constructed, let us suppose the pipe ABR full of water, and the valve C to be opened, the water will lift the valve D, and escape with a velocity due to the height of the reservoir. In a short time, the water having acquired an additional velocity, raises the valve G, which shuts the passage, and prevents the escape of the water. The consequence of this is, that all the included water exerts suddenly a hydrostatical pressure on every part of the pipe, compressing at the same time the air in the annular space *ii*, which by its elasticity diminishes the violence of the shock. This hydrostatical pressure opens the valves at E, and a portion of the water flows into the air vessel F, and condenses the air which it contains. The valves at E now close, preventing the return of the water into the pipe, and the water recoils a little in the tube with a slight motion from B to A, in consequence of the reaction or elasticity of the compressed air in *ii*, and also of the metal of the pipe, which must have yielded a little to the force exerted upon it in every direction. The recoil of the water towards A produces a slight aspiration within the head R of the ram, which causes the valve D to descend by its own weight, and prevent the water X which covers it from descending into the tube. The air, however, passes through the pipe *lk*, opens the valve *k*, and a small quantity is sucked into the annular space *ii*; but the quantity is very small, as the valve *k* closes as soon as the current of air becomes rapid. During the recoil towards A, the valve C, being unsupported, falls by its own weight; and when the force of recoil is expended by acting on the water in the reservoir PQ, the water begins again to flow along ABR, and the very same operation which we have described is repeated without end, a portion of water being driven into the air vessel F at every ascent of the valve C. The air in this vessel being thus highly compressed, will exert a force due to its elasticity upon the surface of the water in the vessel F, and will force it up through the pipe M to a height which is sufficient to balance the elasticity of the included air.

The small quantity of air which is drawn into the annular space *ii* through the air tube *lk* at each aspiration, causes an accumulation of air in the space *ii*; and when the aspiration of recoil takes place, a small quantity of air passes from *ii*, and proceeds along the pipe till it arrives beneath the valves at E, and lodging in the small space beneath the valves, it is forced into the air vessel at the next stroke, and thus affords a constant supply of air to the vessel. The valves make in general from fifty to seventy pulsations in a minute.

When the fall of water, or PQ, is five feet, and the pipe AB six inches in diameter and fourteen feet long, a machine with its parts proportioned as in the figure will raise water to the height of 100 feet. It will expend about seventy cubic feet per minute in working it, and will raise about two and a third cubic feet per minute to the height of 100 feet.

The third general division of the subject relates to the means by which motion and power may be obtained from liquids, and includes the general consid-

eration of water-wheels and other contrivances for moving machinery. Motion is generally obtained from water, either by exposing obstacles to the action of its current, as in water-wheels, or by arresting its progress in movable buckets, or receptacles which retain it during a part of its descent.

Water-wheels have three denominations, depending on their particular construction, on the manner in which they are set or used, and on the manner in which the water is made to act upon them; but all water-wheels consist, in common, of a hollow cylinder or drum, revolving on a central axle or spindle, from which the power to be used is communicated, while their exterior surface is covered with vanes, float-boards, or cavities, upon which the water is to act. The undershot wheel is the oldest construction of this kind: it is merely a wheel, furnished with a series of plane surfaces or floats projecting from its circumference, for the purpose of receiving the impulse of the water which is delivered under the wheel. As it acts chiefly by the momentum of the water, the positive weight of which is scarcely called into action, it is only proper to be used where there is a great supply of water always in motion. It is the cheapest of all water-wheels, and is more applicable to rivers in their natural state than any other form of the wheel; it is also useful in tide-currents, where the water sets in opposite directions at different times, because it receives the impulse equally well on either side of its floats. In the overshot wheel, the circumference is furnished with a series of cavities or buckets, into which the water is delivered from above. The buckets on one side, being erect, will be loaded with water, and the wheel will be thus set in motion; the mouths of the loaded buckets, being thus turned downwards by the revolution of the wheel, will be emptied, while the empty buckets are successively brought under the stream by the same motion, and filled. The breast-wheel differs from this in receiving the water a little below the level of the axle, and has floats instead of buckets. In these two wheels, the weight and motion of the water are used, as well as its momentum, and a much greater power is, therefore, produced with a less supply of water than is necessary for the undershot wheel. In order to permit these wheels to work with freedom, and to the greatest advantage, it is necessary that the *back* or *tail* water as it is called, or that which is discharged from the bottom of the wheel, should have an uninterrupted passage off; for otherwise it accumulates, and forms a resistance to the float-boards. One of the simplest methods of removing it consists of forming two drains through the masonry, each side of the water-wheel, so as to permit a motion of the upper water to flow downwards the tail, in front of the wheel. The water, thus brought down with great impetuosity, drives the tail-water before it, and forms a hollow place, in which the wheel works freely, even if the state of the water be such that it would otherwise form a tailing of from twelve to eighteen inches. The drains may be closed whenever the water is scarce. Numerous other contrivances are in use, which our limits will not permit us to describe. See *Bristol, Over-shot and Under-shot, and Wheel*.

In Barker's centrifugal mill, the water does not act, as in the contrivances above noticed, by its weight or momentum, but by its centrifugal force and the reaction that is produced by the flowing of the water on the point immediately behind the orifice of discharge. It consists of a revolving vertical tube, which receives the water at the top, and at the bottom of which is a horizontal tube, extending on each side of it, and having apertures opening in opposite sides, near the ends. The water spouting

from these apertures keeps up, by its reaction, a constant rotary motion.

**HYDRIADS.** The Hydriads, in mythology, were a kind of water-nymphs, who danced with the Hamadryads, to the sound of the pipe of Pan.

**HYDRO** ; two syllables which occur in a number of scientific words ; derived from the Greek *ὕδωρ*, water. See the following articles.

**HYDROCEPHALUS.** See *Dropsy*.

**HYDROGEN** ; a simple non-metallic body, forming acids by its union with chlorine, iodine, and bromine, and hence termed an *acidifiable* body, and producing water by its combination with oxygen, in allusion to which the name *hydrogen* (from *ὕδωρ*, water) has been applied. The most simple state in which we can procure it is in that of a gas, i. e., in union with caloric, and possibly with electricity and light. To effect this, water is always employed ; and one of the following arrangements is adopted : water in the state of vapour is passed over the metallic iron heated to redness, by adjusting a retort, half filled with this fluid, to one extremity of an iron tube containing clean iron wire, and laid across a heated furnace, the other extremity having a bent tube connected with it and dipping under the shelf of a pneumatic cistern ; the water in the retort is made to boil briskly, and the steam to come in contact with the heated iron ; upon which hydrogen gas is copiously disengaged, and collected in the pneumatic apparatus. Or, slips of sheet zinc, iron filings or turnings, or small iron nails, are introduced into a small gas-bottle with a bent tube, or into a common retort, upon which sulphuric acid, diluted with five or six times its weight of water, is poured ; effervescence ensues, and the escaping gas may be collected in the usual manner. One troy ounce (480 grains) of zinc gives 356 cu. measures = about 676 cubic inches ; and 1 ounce of iron, 412 cu. measures = 782 cubic inches, of hydrogen gas. The hydrogen obtained in these processes is not absolutely pure. The gas evolved during the solution of iron is contaminated by a compound formed from hydrogen and the carbon contained in the iron. This compound, which is a volatile oil, is removed by transmitting the gas through alcohol. The gas obtained by means of zinc is more free from impurities ; though the small proportion of sulphur and carbon still remaining in the zinc of commerce, gives rise to the same compound as in the former case, and also to a little sulphureted hydrogen. The impurities in this instance are removed by passing the gas through a solution of caustic potash. Thus purified, hydrogen gas has neither taste nor odour ; it is colourless, and the lightest of all ponderable matter known, its specific gravity being 0.068, that of the atmospheric air being 1.000, or about  $14\frac{1}{2}$  times lighter than common air. This remarkable levity allows it to ascend with the greatest readiness through all liquids and gases, and is the cause of its being employed to fill balloons ; which, notwithstanding the weight of the materials of which they are constructed, are sufficiently light, compared with the atmosphere, to rise to very great elevations, or until they meet with a medium whose density is such as to render them stationary. (See *Aeronautics*.) Hydrogen gas is a powerful refractor of light, and has hitherto resisted all attempts to compress it into a liquid. It is sparingly absorbed by water, 100 cubic inches of that liquid dissolving about  $1\frac{1}{2}$  of the gas. It is incapable of supporting respiration ; nor is it a supporter of combustion ; for when a lighted taper is passed up into an inverted glass full of hydrogen gas, it is immediately extinguished. But its most characteristic property is that of its inflammability, though, like other combustibles, it requires the aid of a sup-

porter for enabling its combustion to take place. This is exemplified by bringing a lighted candle or taper to the mouth of a narrow jar, or wide-mouthed bottle, filled with the gas ; it is immediately kindled, but only burns where it is in contact with the air, the combustion going on quietly in successive strata from the orifice to the bottom of the vessel. Mingled with oxygen gas, no action takes place so long as the compound remains cold ; but, on the approach of a flame, the whole is kindled at the same instant ; a flash of light passes through the mixture, followed by a violent explosion. The report is the loudest when the proportions observed in the mixture are two volumes of hydrogen and one of oxygen. The same phenomena take place, though less strikingly, when atmospheric air is substituted for oxygen gas : in the latter case, however, the proportions are two measures of hydrogen to five or six of air. And not only is hydrogen gas inflamed when in contact with air or oxygen gas by the contact of a burning taper, but by a solid body heated to redness, and by the electric spark. If a jet of hydrogen be delivered upon recently prepared spongy platinum (see *Platinum*), this metal very quickly becomes red-hot, and then sets fire to the gas. The electric spark ceases to cause detonation when the explosive mixture, formed of two measures of hydrogen to one of oxygen, is diluted with twelve times its volume of air, fourteen of oxygen, or nine of hydrogen, or when it is expanded to sixteen times its bulk by diminished pressure. Sudden and violent compression, likewise, causes an explosion of the explosive mixture ; apparently from the heat emitted during the operation ; for an equal degree of condensation, slowly produced, has not the same effect. When the action of heat, the electric spark and spongy platinum no longer cause an explosion, a silent and gradual combination between the gases may still be occasioned by them. Oxygen and hydrogen gases unite slowly with one another when exposed to a temperature above the boiling point of mercury, and below that at which glass begins to appear luminous in the dark. An explosive mixture, diluted with air to too great a degree to explode by electricity, is made to unite silently by a succession of electric sparks. Spongy platinum causes them to unite slowly, though mixed with 100 times their bulk of oxygen gas. A very high temperature is excited by the combustion of hydrogen gas, especially when it is burned in oxygen gas, as in the compound blow-pipe of doctor Hare. (See *Compound Blow-pipe*.) Water is the sole product of the combustion of hydrogen—a fact first demonstrated by Cavendish, who burned oxygen and hydrogen gases in a dry glass vessel, and obtained a quantity of pure water exactly equal to that of the gases which had disappeared during the experiment. The synthetic proof of the composition of water is obtained also by detonating two measures of hydrogen, mixed with one of oxygen, in a tube, over the mercurial cistern ; the whole is condensed into water. Lavoisier first exhibited the composition of water analytically, by passing a known quantity of watery vapour over metallic iron heated to redness in a glass tube. Hydrogen gas was disengaged ; the metal in the tube was oxydized ; and the weight of the hydrogen, added to the increase which the iron had experienced from combining with oxygen, exactly corresponded to the quantity of water which had been decomposed. Its composition by volume is very clearly shown by galvanism. On resolving water into its elements by this agent, and collecting them in separate vessels, two measures of hydrogen to one of oxygen are obtained ; and, on the other hand, these gases, when inflamed by the electric spark, unite in the exact ratio of one to two, whatever may

be their relative quantity in the mixture. Hence the composition of water, by weight and measure, is,

	By weight.	By volume.
Oxygen, .....	8	1
Hydrogen, .....	1	2

(For a further account of the properties of water, see that article.) The processes for procuring a supply of hydrogen, described at the commencement of the present article, will now be intelligible. The first is founded on the fact that iron, at a red heat, decomposes water, the oxygen of which unites with the metal, while the hydrogen gas is set free. That the hydrogen which is evolved when zinc or iron is put into dilute sulphuric acid, is derived from the water, is obvious from the consideration, that of the three substances, iron or zinc, sulphuric acid, and water, the last is the only one which contains hydrogen. The product of the operation, besides hydrogen, is the sulphate of the protoxide of iron, if iron is used, or of the oxide of zinc, when zinc is employed. Hydrogen, therefore, is one of the most abundant substances in nature. It forms, as has been stated, eight-ninths of water; besides, with carbon and oxygen, it enters into the composition of all vegetable substances; and, with oxygen, carbon, and nitrogen, it forms a part of all animal substances. Large quantities of it, often united with more or less carbon, are continually evolved into the atmosphere from the decomposition of vegetable and animal matters.

**HYDROGRAPHY**; that part of geography which treats of waters.—*Hydrographic maps*; such as make the rivers and other collections of water their chief subject.

**HYDROMETER**, (*Greek*), measurer of density (for fluids), is an instrument, which, being immersed in fluids, as in water, brine, beer, brandy, determines the proportion of their densities or their specific gravities, and thence their qualities. The use of the hydrometer depends on the following propositions—

1. The hydrometer will sink in different fluids in an inverse proportion to the density of the fluids; 2. the weight required to sink a hydrometer equally far in different fluids, will be directly as the densities of the fluids. Each of these two propositions gives rise to a particular kind of hydrometer; the first with the graduated scale, the second with weights. The latter deserves the preference. (See *Traité d'Aréométrie* de M. Francœur, and *Le Cours de Physique* de M. Biot.)—There are various instruments used as hydrometers; one is a glass or copper ball, with a stem, on which is marked a scale of equal parts or degrees. The point to which the stem sinks in any liquid being ascertained and marked on this scale, we can tell how many degrees any other liquid is heavier or lighter, by observing the point to which the stem sinks in it. Another kind is formed by preparing a number of hollow glass beads, of different weights, and finding which bead will remain stationary in any liquid, wherever it is placed. An instrument of great delicacy, which will even detect any impurity in water too slight to be detected by any ordinary test, or by the taste, consists of a ball of glass three inches in diameter, with another joining it, and opening into it one inch in diameter. A wire, about ten inches long and one-fortieth of an inch in diameter, divided into inches and tenths, is screwed into the larger ball. A tenth of a grain, placed on the top of the wire will sink it a tenth of an inch. Now it will stand in one kind of water a tenth of an inch lower than in another, which shows that a bulk of one kind of water, equal to the bulk of the instrument (which weighs 4000 grs.), weighs one tenth of a grain less than an equal bulk of the other kind of water; so that a difference in specific gravity of one

part in 40,000 is detected. The areometer is more simple and accurate. A glass phial, about two inches in diameter, and seven or eight long, is corked tight; into the cork is fixed a straight wire, one twelfth of an inch in diameter, and thirty inches long. The phial is loaded with shot, so as to sink in the heaviest liquid, leaving the wire just below the surface. The liquor is then placed in a glass cylinder, three or four feet long, with a scale of equal parts on the side, by which the point to which the top of the wire sinks is marked. This instrument is so delicate, that the sun's rays, falling upon it, will cause the wire to sink several inches; and it will rise again when carried into the shade.

Nicholson made an improvement by which the hydrometer is adapted to the general purpose of finding the specific gravity both of solids and fluids. A is a hollow ball of copper, B a dish affixed to the ball by a short slender stem D; C is another affixed to the opposite side of the ball by a kind of stirrup. In the instrument actually made, the stem D is of hardened steel 1-40 of an inch in diameter, and the dish C is so heavy as in all cases to keep the stem vertical when the instrument is made to float in any liquid. The parts are so adjusted, that the addition of 1000 grains in the upper dish B, will just sink it in distilled water, at the temperature of 60° of Fahrenheit's thermometer, so far that the surface shall intersect the middle of the stem D. Let it now be required to find the specific gravity of any fluid. Immerse the instrument in it, and by placing weights in the dish B cause it to float, so that the middle of its stem D shall be cut by the surface of the fluid. Then, as the known weight of the instrument, added to 1000 grains, is to the same known weight added to the weight used in producing the last equilibrium, so is the weight of a quantity of distilled water displaced by the floating instrument, to the weight of an equal bulk of the fluid under examination. And these weights are in the direct ratio of the specific gravities. Again, let it be required to find the specific gravity of a solid body, whose weight is less than 1000 grains. Place the instrument in distilled water, and put the body in the dish B. Make the adjustment of sinking the instrument to the middle of the stem, by adding weight in the same dish. Subtract those weights from 1000 grains, and the remainder will be the weight of the body. Place now the body in the lower dish C, and add more weight in the upper dish B, till the adjustment is again obtained. The weight last added will be the loss the solids sustain by immersion, and is the weight of an equal bulk of water. Consequently the specific gravity of the solid is to that of water, as the weight of the body to the loss occasioned by the immersion. This instrument was found to be sufficiently accurate to give weights true to less than one-twentieth of a grain.

**HYDROPHANE**. See *Opal*.

**HYDROPHOBIA** (from *hydro*, water, and *phobos*, fear); a specific disease arising from the bite of a rabid animal. The animals most liable to be afflicted with madness are dogs; but cats, wolves, foxes, &c., are also subject to it. The following description of the way in which rabies affects dogs, is from a communication in the *Sporting Magazine*, September, 1825:—The symptoms of rabies in the dog are the following, and are given nearly in the order in which they usually appear:—An earnest licking, or scratching, or rubbing, of some particular part; sullenness, and a disposition to hide from observation; considerable costiveness, and occasional vomit-

ing; an eager search for indigestible substances—as bits of thread, hair, straw, and dung; an occasional inclination to eat its own dung, and a general propensity to lap its own urine. The two last are perfectly characteristic. The dog becomes irritable; quarrels with his companions; eagerly hunts and worries the cat; mumbles the hand or foot of his master, or perhaps suddenly bites it, and then crouches and asks pardon. As the disease proceeds, the eyes become red; they have a peculiar bright and fierce expression; some degree of strabismus, or squinting, very early appears—not the protrusion of the *membrana nictitans*, or haw, over the eye, which, in distemper, often gives the appearance of squinting, but an actual distortion of the eyes; the lid of one eye is evidently more contracted than that of the other; twitchings occur round that eye; they gradually spread over that cheek, and finally over the whole face. In the latter stage of the disease, that eye frequently assumes a dull green colour, and at length becomes a mass of ulceration. After the second day, the dog usually begins to lose a perfect control over the voluntary muscles. He catches at his food with an eager snap, as if uncertain whether he could seize it; and he often fails in the attempt. He either bolts his meat almost unchewed, or, in the attempt to chew it, suffers it to drop from his mouth. This want of power over the muscles of the jaw, tongue, and throat increases, until the lower jaw becomes dependent, the tongue protrudes from the mouth, and is of a dark, and almost black colour. The animal is able, however, by a sudden convulsive effort, to close his jaws, and to inflict a severe bite. The dog is in incessant action; he scrapes his bed together, disposes it under him in various forms, shifts his posture every instant, starts up, and eagerly gazes at some real or imaginary object; a peculiar kind of delirium comes on; he traces the fancied path of some imaginary object floating around him; he fixes his gaze intently on some spot in the wall or partition, and suddenly plunges and snaps at it; his eyes then close, and his head droops, but the next moment he starts again to renewed activity; he is in an instant recalled from this delirium by the voice of his master, and listens attentively to his commands; but as soon as his master ceases to address him, he relapses into his former mental wandering. His thirst is excessive (there is no hydrophobia, or fear of water, in the dog), and, the power over the muscles concerned in deglutition being impaired, he plunges his face into the water up to the very eyes, and assiduously, but ineffectually, attempts to lap. (In Johnson's *Shooter's Companion*, the author observes, "In those instances of hydrophobia which have fallen under my notice, the animal has always been capable of lapping; however, in the disease called *dumb madness*, I have noticed symptoms similar to the above.") His desire to do mischief depends much on his previous disposition and habits. I have known it not to proceed beyond an occasional snap, and then only when the animal was purposely irritated; but with the fighting dog, the scene is often terrific. He springs to the end of his chain; he darts with ferocity at some object which he conceives to be within his reach; he diligently tears to pieces every thing about him; the carpet or rug is shaken with savage violence; the door or partition is gnawed asunder; and so eager is he in this work of demolition, and so regardless of bodily pain, that he not unfrequently breaks one or all of his tushes. If he effects his escape, he wanders about, sometimes merely attacking those dogs which fall in his way; and at other times he diligently and perseveringly hunts out his prey: he overcomes every obstacle to

effect his purpose; and, unless he has been stopped in his march of death, he returns in about four and twenty hours, completely exhausted, to the habitation of his master. He frequently utters a short and peculiar howl, which, if once heard, can rarely be forgotten; or if he barks, it is with a short, hoarse, inward sound, altogether dissimilar from his usual tone. In the latter stages of the disease, a viscid saliva flows from his mouth, with which the surface of the water that may be placed before him, is covered in a few minutes; and his breathing is attended with a harsh, grating sound, as if impeded by the accumulation of phlegm in the respiratory passages. The loss of power over the voluntary muscles extends, after the third day, throughout his whole frame, and is particularly evident in the loins; he staggers in his gait; there is an uncertainty in all his motions; and he frequently falls, not only when he attempts to walk, but when he stands, balancing himself as well as he can. On the fourth or fifth day of the disease, he dies, sometimes in convulsions, but more frequently without a struggle. After death, there will invariably be found more or less inflammation of the mucous coat of the stomach; sometimes confined to the rugæ, at other times in patches, generally with spots of extravasated blood, and occasionally intense, and occupying the whole of that viscus. The stomach will likewise contain some portion of indigestible matter (hair, straw, dung), and, occasionally, it will be completely filled and distended by an incongruous mass. The lungs will usually present appearances of inflammation, more intense in one, and generally the left lung, than in the other. Some particular points and patches will be of a deep colour, while the neighbouring portions are unaffected. The sublingual and parotid glands will be invariably enlarged, and there will also be a certain portion of inflammation, sometimes intense, and at other times assuming only a faint blush, on the edge of the epiglottis, or on the rima glottidis, or in the angle of the larynx at the back of it.

The hydrophobia seems to be spontaneous, and capable of being communicated only in certain animals—the dog, the wolf, the fox, and the cat. All animals which have become rabid by a bite, do not appear to be able to transmit it to others; as the hog, cow, sheep. In regard to man, it is not certain whether the disease is communicable from the human subject. The hydrophobia is not commonly manifested in the time of greatest cold or greatest heat, but usually in March and April in wolves, and in May and September in dogs. It is rare in very warm or very cold climates. No particular cause of the rabies is known; it is a mistake to attribute it to a total privation of food, as a great number of experiments prove that this is not the effect of such a treatment. All observations seem to prove the existence of a rabid virus, which is more violent when it proceeds from wolves than from dogs; as, out of a given number of persons bitten by a rabid wolf, a greater number will die than out of the same number bitten by a dog. The communication of the virulent hydrophobia by inoculation cannot be denied, and is the best proof of the existence of the virus. The virus appears to be contained solely in the saliva, and does not produce any effect on the healthy skin. But if the skin is deprived of the epidermis, or if the virus is applied to a wound, the inoculation will take effect. The development of the rabid symptoms is rarely immediate; it seldom takes place before the fortieth or after the sixtieth day. It begins with a slight pain in the scar of the bite, sometimes attended with a chill; the pain extends and reaches the base of the breast, if the bite was on the lower limbs, or the

throat, if on the upper extremities. The patient becomes silent; frightful dreams disturb his sleep; the eyes become brilliant; pains in the neck and throat ensue. These symptoms precede the rabid symptoms two or three days. They are followed by a general shuddering at the approach of any liquid or smooth body, attended with a sensation of oppression, deep sighs and convulsive starts, in which the muscular strength is much increased. After the rabid fit, the patient is able to drink. The disposition to bite does not appear to belong to any animals except those whose teeth are weapons of offence; thus rabid sheep butt furiously. A foamy, viscid slaver is discharged from the mouth; the deglutition of solid matters is difficult; the respiration hard; the skin warm, burning, and afterwards covered with sweat; the pulse strong; the fit is often followed by a syncope; the fits return at first every few hours, then at shorter intervals, and death takes place generally on the second or third day. A great number of applications have been recommended, but without success. The treatment of the disease is of two sorts; the one consists in preventing its development; the other in checking its progress. The former consists in cauterizing the wound with iron heated to a white heat, the pain of the cautery being less, as the temperature is greater. The cautery is preferable to the use of lotions, liniments, &c., but it should be employed within twelve hours after the bite. It has been said that, in patients who were about to become rabid, several little pustules filled with a serous matter appeared under the tongue, the opening of which would prevent the disease; but this is not well established. Various remedies have been prescribed for the cure of a declared hydrophobia. Bleeding, even to syncope, appears to have produced the greatest effect, but without complete success. Preparations of opium administered internally or by injection, mercurial frictions, belladonna, emetics, sudorifics, purgatives, &c., have been tried ineffectually. Yet the physician should not despair, as a remedy which has failed in one case may succeed in another. Above all, the patient should be treated gently, and his sufferings alleviated by consulting his comfort as much as possible; and the attendants should not forget, that there is no instance of the rabies having been communicated from one man to another.

HYERES. See *Hieres*.

HYGIEIA, the sweet, smiling goddess of health, was the daughter of Aesclepias, or Esculapius. Hesiod, Homer, and Pindar, who were unacquainted with any such divinity as Esculapius, of course knew nothing of such a goddess. This fable, probably, had its origin at the time in which the worship of Esculapius began. When the healing art was practised in his temple, the god of medicine and the goddess of health were always in close connexion. Her temple was placed near his, and her statues were even erected in it. She is represented as a maid of slender form, with a long flowing robe. Her distinguishing characteristic is a feminine softness. She has a bowl in her hand, from which a serpent is eating—an emblem of the art of medicine.

HYGROMETER, HYGROSCOPE. It is of the greatest importance for meteorology to ascertain at any time the quantity of water contained in the air. The instruments used for this purpose are called *hygrometers* (measures of moisture). Daily experience shows, that some bodies possess a great capability of absorbing the humidity suspended in the atmosphere, and, according to their respective construction, becoming longer or shorter, in the direction of the fibres of their length or breadth. Thus, for example, coriage and catgut are shortened and

untwisted by moisture. And this observation is the foundation of the hygrometer of Lambert, which, however, on account of the irregularity of the motion produced in the catgut by the humidity, does not altogether answer its purpose, but properly deserves the name of a *hygroscope* (shower of moisture). Saussure and De Luc, therefore, sought for other substances, which are regularly lengthened or shortened by the absorption or loss of humidity. Saussure believed this property might be found in a human hair, freed from all unctuousity by boiling in ley; De Luc, in a very thin piece of whalebone, cut in a direction transverse to the fibre. Saussure stretches the hair, properly prepared, and fastened at one end, over a delicate and easily movable wheel, by a small weight, while De Luc makes use of a small wire of gold to stretch the whalebone. Whenever the hair in Saussure's hygrometer is lengthened or shortened by the action of the moisture or dryness, the wheel, and an index attached to it, must be turned, and thus mark the increase or diminution of the water suspended in the atmosphere. But to find the absolute quantity, it is necessary to fix the points of extreme moisture and dryness. Saussure fixes the point of extreme moisture in his hygrometer by placing it in a glass receiver, which is enclosed in water and moistened with water within; De Luc, on the other hand, by simply immersing his hygrometer in water. The point of extreme dryness Saussure determines by placing his hygrometer under a receiver, which stands on a tin plate, heated to a red heat, and covered with red hot potash; De Luc by suspending the hygrometer in a close vessel, partly filled with hot quicklime.

HYLAS; a beautiful boy, of whose parents different accounts have been given. Hercules, who loved him, took him with him on the Argonautic expedition. But Hylas having landed in the region of Troy to draw water, the nymphs saw him, and were so enraptured with his beauty, that they drew him down into the crystal water. Hercules called him in vain on the shore, and, on this account, delayed his return to the ship *Argo*, which continued her voyage to Colchis without him.

HYMEN, HYMENEUS; the god of marriage among the later Greeks, by whom the marriage itself and the bridal song were also called *Hymeneus*. But it is probable that the god of marriage derived his name from the nuptial song, since we find it mentioned earlier than the divinity. According to the commonly received opinion, Hymen was so beautiful a youth, that he might easily have been mistaken for a maiden. But he was poor; and therefore his love, though not unrequited, was unfortunate. In order to be near his mistress, he dressed himself like a woman on the festival of the Eleusinian Ceres, and mingled in the ceremony. During the celebration, a band of pirates broke in, and carried him off with the crowd of females. The pirates having landed on a desolate island, and fallen asleep through weariness, he destroyed them all, and hastened back to Athens, where he promised to bring back all the damsels that had been carried off, on condition of being united to his mistress. A joyful consent was given, and, because his marriage was so fortunate, he was commemorated in the nuptial songs, till he was deified. Other traditions also are handed down respecting him, and nothing certain is known about his descent. Sometimes he is called the son of the musician Magnes; sometimes of Bacchus and Venus; and sometimes of Apollo and a muse, but whether of Terpsichore, Urania, Clie, or Calliope, is uncertain. Claudian says that Venus gave the son of the muse authority over marriages; so that, without invoking him, no one dared to solemnize them, or to light the

nuptial torch. He was in the train of Venus, and among the companions of Cupid. No marriage took place without his being invoked to sanction it. He is described as having around his brows the flower of marjoram, in his left hand the flame-coloured nuptial veil, in his right the nuptial torch, and on his feet golden sandals. Song and dance accompany him. At the death of Adonis, Bion describes him as extinguishing his torch, and tearing the nuptial wreath. If we may believe the beautiful hymn of Catullus to this god, Hymen has his seat on Helicon, among the muses.

**HYMETTUS**; a mountain in Attica, now called *Treleuano*, distinguished for the quantity and excellence of its honey, which the bees here collect. This honey is always fluid. Jupiter, who was worshipped on this mountain, received therefrom the name of *Hymettius*.

**HYMN**; a song of praise, which was sung in honour of gods or heroes, on festivals, with the accompaniments of music and dancing. The hymns varied in name and character, according to the gods in whose honour they were sung. They were called *diagrammics*, *peans*, &c. Afterwards, every song of praise, or ode, wherein any thing elevated or sublime was sung, went by this name. In this respect, many of the Hebrew psalms are to be called *hymns*. In consequence of their Oriental character, and the nature of their religion, these breathe a more fervid spirit of devotion than those of the Greeks. These last were anciently almost entirely epic, like those of Homer. They recounted legends of the gods, as well as the deeds of men. Those of later times, of Callimachus and Pindar, for instance, are almost entirely lyric. The early Christian hymns, are, in a great measure, lyric, and express the feelings of one who longs earnestly for invisible things. The English hymns, commonly sung in the churches, are, generally, far from having the original character of a hymn, and devoid of the fervent lyric strain, the glowing feeling, which characterize it. In the Greek and Latin church, certain songs are called *hymns* (in the latter ninety-six in number), which, at certain periods, are sung in the churches standing, the psalms being sung sitting. The first of these hymns are said to have been composed in the Greek church by bishop Hierotheus, in the Latin church by St Hilarius, bishop of Poitiers, and, after him, by St Ambrosius, bishop of Milan. Some of them must be ranked among the first productions of sacred poetry. The popes Gelasius and Gregory also composed hymns, as did also Synesius, Cosmas of Jerusalem, Johannes Damascenus, Theophanes, Prudentius, Beda, Sedulius, Paulinus, Venantius, Fortunatus, Paulus Diaconus, Thomas Aquinas. The fervent hymn, by which the Franciscans greet the first rays of the sun, is celebrated. These old hymns are written in iambs, trochees, &c., often in irregular metre, also in rhymes. In 1629, pope Urban VIII. improved them. The use of hymns was sanctioned by the fourth council, at Toledo, in 633. They are sung in the canonical hours. (q. v.) Several of these hymns have particular names, as *Hymni Epistolici*, sung in the mass before the reading of the epistles; *Hymni Evangelici*, sung before the reading of the gospel; *Hymnus Ambrosianus*, or *Te Deum laudamus*; *Hymnus Angelicus*, the same with *Gloria in Excelsis Deo* (see *Doxology*); *Gloria Patri* (see *Doxology*); *Hymnus Marianus*, the same with the *Magnificate*, &c.

**HYPATIA**; a female philosopher of the eclectic sect, the daughter of Theon, a celebrated mathematician, who governed the Platonic school in Alexandria, towards the close of the fourth century, at which period she was born. As she early exhibited proof of extraordinary genius and judgment, her

father, besides educating her in all the accomplishments of her own sex, made her mistress not only of the different branches of polite learning, but of geometry and astronomy, as then understood. She finally studied philosophy; and such was her reputation, that she became a preceptress in the school in which Ammonius, Hierocles, and other celebrated philosophers, had presided, and the votaries of philosophy crowded to Alexandria. Her ready elocution and graceful address, united with deep erudition and sound judgment, procured her the admiration of all her hearers. She discovered none of the vanity or pride of learning, and, although eminently beautiful, was equally virtuous. Her house became the resort of all the persons of learning and distinction in Alexandria, and, among others, of Orestes the governor. At this time, the patriarch of Alexandria was Cyril, a prelate in the highest degree intolerant and haughty, who was guilty of encouraging the populace to plunder the Jews. Orestes laid the affair before the emperor, who declining to interfere, Alexandria became a frequent scene of tumult between the partisans of the governor and of the bishop. The intimacy of the governor with Hypatia aroused the anger and jealousy of Cyril; and in consequence she was much calumniated by his monkish partisans and the Christian populace. Their blind resentment at length led them to a conspiracy against her life, and a furious band of assassins seized upon her, as she was returning home from the schools, dragged her through the streets of Alexandria, stripped her naked, and finally tore her limb from limb, with circumstances of the greatest barbarity, and committed her mangled members to the flames. This infamous transaction took place in 415, under the reign of Theodosius II.

**HYPERBOREANS** (those who dwelt beyond the domain of Boreas or the north wind); the name given by the ancients to the unknown inhabitants of the North and West, who were reported always to enjoy a delightful climate. In earlier times, the dwelling of Night and the realm of Shades, and the Cimmerians, who lived in perpetual darkness, were placed in the west. Instead of these, the ancients found there a contented and somewhat civilized people, who inhabited a soil rich in gold, and free from the cold north winds of Greece, against which the Alps and Pyrenees appeared to screen them. Hence originated the report of a people enjoying perpetual health and long life; and who, being the especial favourites of Apollo, worshipped him, with music and sacrifices, on plains rich in fruit, and protected from the north wind, and who, for thousands of years, lived in a perpetual succession of pleasures. As the West gradually became better known, the name of *Hyperboreans* was applied exclusively to the North.

**HYPERION**. See *Titans*.

**HYPERMNESTRA**; one of the fifty daughters of Danaus, who married Lynceus, son of Ægyptus. She disobeyed her father's bloody commands, who had ordered her to murder her husband the first night of her nuptials, and suffered Lynceus to escape unhurt from the bridal bed. Her father summoned her to appear and answer for her disobedience, but the people acquitted her, and Danaus was reconciled to her and her husband, to whom he left his kingdom at his death. Some say that Lynceus returned to Argos with an army, and that he conquered and put to death his father-in-law, and usurped his crown.

**HYPERSTHENE**; a mineral principally found, in rolled masses, upon the coast of Labrador, and hence sometimes called *Labrador hornblende*. It has a lamellar structure, parallel with the diagonals and sides of a rhombic prism of 87° and 93°. The cleavage takes place most readily parallel to the short diagonal of the prism, and the planes, produced by

this division, present an eminently metallic lustre, usually of a copper-red colour. Colour, grayish or greenish black; opaque; hardness equal to that of quartz; specific gravity, 3.389. It consists of silice 54.25, magnesia 14.00, alumine 2.25, lime 1.50, oxide of iron 24.50, and water 1.00.

**HYPO**, the Greek *υπο*, a preposition which occurs in many compound words used in English, and mostly signifies *under*.

**HYPPOCHONDRIASIS** (from the Greek *υπο*, under, and *χονδρις*, the cartilage; hence *hypochondrium*, the region of the abdomen, which lies under the short ribs); one of the most troublesome of diseases. Its seat is in the abdomen, particularly under the short ribs; but when it has increased to a certain degree, it manifests itself, in the most various ways, in the whole body, as there are few diseases of which the hypochondriac does not at some time or other complain. He feels a pressure on the right side, and thinks it is owing to a complaint of the liver; he has pains in the breast, and immediately apprehends inflammation of the lungs; his head feels heavy, and nothing is more certain than an approaching apoplexy; he sees specks before his eyes, and a cataract is unavoidable; if the heart beats stronger than usual, a polypus in that organ is probable; and an unimportant pimple becomes the indication of inveterate ulcers; and so on. All these effects of the disease are explicable from its nature, seat, and causes. Hypochondria is a disturbance of the functions of the nervous system of the abdomen. Hence the sensibility of the nervous system is morbidly heightened, but its power of action lessened. At the same time, the separation between the nervous system of the abdomen and that of the brain is rendered less complete, so that certain feelings reach the brain, and thus affect the thoughts much more than in a state of health. The disturbance in the function of the abdominal nervous system produces next a weakness and disturbance in the digestion, which generally produce the first and most numerous attacks of hypochondria, from which all the others originate, in proportion as the morbid sympathy extends over the whole body. Hence, first, is produced spasmodic contractions under the short ribs, sometimes on one side, sometimes on the other, sometimes in the pit of the stomach; torpidity of the bowels, flatulency, inflation of the abdomen, want of appetite, increased pressure, and, generally, disagreeable feelings after eating. In the progress of the disease, a slow and somewhat difficult inspiration comes on, indescribable anxiety, and pain and giddiness in the head. Also, when the stomach is empty, this organ sometimes suffers pain and sickness, and vomiting takes place. For moments, particularly after digestion is finished, the hypochondriac feels easy, well, and serene; but, all at once, the old complaints seize again upon their victim. The disturbance of the nervous system also has, as well may be conceived, a great influence upon the mind and humour of the patient. Sometimes he is melancholy, sometimes gay to an excess. Uninterruptedly occupied with the state of his body, he takes notice of every feeling, and wishes to have every trifling pain explained, considering every one as a symptom of a serious disease. For every thing he wants physic. In the hours of anxiety, hypochondriacs are constantly in dread of death. Sometimes anxiety attacks them so suddenly, that they must jump up, and cannot find quiet any where. Sometimes memory leaves them, so that they cannot think of their name. In the midst of the most serious conversation, nay, even of prayers, the most ludicrous ideas or images strike them. Others, all at once, feel a desire to perform the strangest actions, from which they can restrain

themselves only with great difficulty. This deplorable disease may be occasioned by any circumstances which disturb the functions of the abdominal nervous system, heighten its sensitiveness, debilitate digestion, and lessen the separation of the reproductive nervous system from the sensitive. Among the chief causes are great exertions of the mind in studying, a sedentary or dissipated life, excess in exciting liquors, particularly coffee; also want of exercise of the physical and mental powers, producing *ennui*. Hypochondria is physically considered not a dangerous disease. It is true, the genuine hypochondriac believes, at least for six days of every week, that his hour is come. He passes a wretched existence, and is a real torment to his family and physician. Hypochondria can be cured but slowly. A hypochondriac must abstain from much physic, but the difficulty is to persuade him to do so. He would often rather take ten medicines than one. He ought to avoid sensual indulgences, but his irritated nerves refuse obedience to duty; he ought to master his feelings, but the body has become the governing power; he ought to take much exercise, but his indolence finds continual excuses for omitting it; he ought to observe a strict diet for years, and condescendingly follow the directions of his physician, but he is impatient to be cured immediately, and his most solemn promises are forgotten in a week; he would have ten physicians at once, not to follow their advice, but to quarrel with all, and to tell them that they know nothing of his case. Thus it happens, that a hypochondriac is seldom entirely cured, but, after having suffered for years, he dies of some additional disease; or, in very advanced age, when the irritability of the nerves is lessened, the disease disappears.

**HYPOGASTRIC** (from *υπο*, under, and *γαστρον*, the abdomen); seated in the lower part of the belly.

**HYPOTHECATION**. See *Bottomry*.

**HYPISPYLE**; daughter of Thoas, king of Lemnos. When the Lemnian women murdered their husbands, in their sleep, because they had taken Thracian slaves for concubines, she alone preserved her father, and concealed him in the island of Chios. Hypsipyle received the Argonauts, who had landed on Lemnos, with great kindness, and bore Jason two sons, Thoas and Euneus. When the Lemnian women discovered that Hypsipyle had preserved her father, they attempted to murder her, and would have accomplished their purpose, had she not saved herself by a timely flight; but she was seized shortly after by pirates, who sold her to king Lycus (or Lycurgus of Nemea), who intrusted her with the education of his son, Opheltes. When the army of the seven princes passed through the territories of Lycurgus, on their way to Thebes, they found Hypsipyle alone in a wood, with the boy at her breast. To procure them refreshments, she put down the boy; but, while she was gone, a serpent killed him. In remembrance of him, the Greeks instituted the Nemean games. Hypsipyle was thrown into confinement, and would have atoned for her misfortune with her life, had not her sons rescued her.

**HYRCANIA**; a province of ancient Persia, encompassed with mountains, and fertile in wine and fruit. It now contains the northern half of Khurasan, and the southern portion of Masanderan, along the Caspian sea. The inhabitants of Hyrcania were probably descended from the northern Scythians. As early as the first century, Hyrcania possessed independent sovereigns, who were often formidable to the Parthian monarchy.

**HYSON TEA**. See *Tea*.

**HYSTERIC**s are with women nearly the same as

hypocondria with men, the difference which really exists arising from the peculiar character and constitution of women. It arises from a morbid excitement of the nervous system, and manifests itself by great uneasiness, unusual susceptibility, occasioning great trouble, often from imaginary causes, and affecting the sufferer even to tears. To these is added the sensation of a ball mounting from the abdomen, and particularly from the pit of the stomach, where the most important nerves concentrate, and occasioning a feeling of strangulation. From the greater susceptibility in the system of women, these affections are more universal, and appear quicker in other parts of the body, particularly in the muscles, than in men. Hence spasms of various kinds, contractions of the neck, pains in the head, fainting fits, palpitation of the heart, appear very frequently, and are sometimes so severe, that persons afflicted with them seem to be dying. These complaints were once ascribed to vapours arising from the stomach, and were called by that name. They

were once very fashionable among the ladies. Women of a delicate habit, and whose nervous system is extremely sensible, are the most subject to hysterical affections; and the habit which predisposes to these attacks is acquired by inactivity and a sedentary life, grief, anxiety, and various physical disorders. They are readily excited, in those who are subject to them, by strong emotions, especially if sudden. Hysterical complaints are best prevented by a judicious care of the moral and physical education of girls. Men of uncommon nervous sensibility are sometimes subject to disorders not essentially different.

HYSTERON PROTERON; two Greek words, meaning *the last first*; hence it is used for an anachronism, but chiefly to designate, in grammar, the figure in which that word which should follow is used first; for instance, *Valet atque vivet* (he is well and lives). It is often used to produce a comic effect; for instance, *All the world and Cork talked of it*.

## I

I; the ninth letter in the English alphabet, and the third vowel. The English language is the only one known to us, which denotes, by this same character, the two totally different sounds of *i* (as in *pine*) and *i* (as in *pin*). In all other languages of Western Europe, it has the sound of *i* in *pin* and *ee* in *beef*, which is the same vowel, only in the former case short, in the latter, long. Those languages which have the sound *i* in *pine* express it by a diphthong; for instance, the German by *ei* and *ai*; and it is, in fact, a real diphthong. The continental *i*, corresponding to the English *ee*, is produced by breathing out, whilst the lips are slightly parted, the mouth drawn back a little at the corners, and the tongue curved upwards, yet not so as to touch the roof of the mouth. If the tongue touches the roof of the mouth, the lips remaining in the same position, the sound of *j* is produced, which change takes place, particularly if *i* precedes another vowel. This circumstance, and the near affinity of the two sounds, are the reason that, in some languages, particularly in Latin, they have the same character; hence it was said, *i* is a vowel in some cases, and a consonant in others. In all Latin words of Latin origin, *i* preceding a vowel (unless it follows another vowel), is a consonant, as *Ianus* (*Janus*), *conicio* (*conficio*); but in words of Greek origin, it is a vowel, as *iambus*, *iaspis*. In words of Hebrew origin, it varies; in *Iacobus* (*Claudian*, *epigr.* 27), it is a vowel: in *Iudeus*, a consonant. With the propagation of Christianity, Latin became, in many respects, the model of other languages, and this peculiarity of *i* was also adopted by most of them; so that, even after two different signs (the *i* and *j*) had been adopted for the vowel and the consonant sound of *i*, they nevertheless were, and still are, mixed together in dictionaries; but the fact that they are distinct in nature (though nearly akin), and have distinct characters, sufficiently authorizes us to separate them. As the position of the mouth required for pronouncing the *i* of the European continent (*ee*) is such, that it can easily be assumed from the position necessary for the pronunciation of other vowels, we find *i*, in many languages, the final vowel

of several diphthongs; as, in German, *ei*, *ai*; in French, *ai*, *oi*, *ui*, &c.; and these sounds at last actually became one. In the Greek, the *i* (*iota*) was always a vowel. As a numeral, it signified *ten*; with a little line under it (*ι*), *ten thousand*. The Romans used *I* to signify *one*, and they continued to count with it up to four (*I*, *II*, *III*, *IIII*). The Roman *I*, put before a *V*, takes away the value of one; hence *IV* is equal to four; and, placed after *V*, it adds one; hence *VI* is equal to six. The dot over the *i* originated in the fourteenth century. *I*, on Roman coins, was the mark of the *as*, in value and weight. As an initial letter, it stands for *idea*, *imperator*, *imperii*, *indulgentia*, *invictus*, &c. It is a French proverb of a person occupied with trifles—*Il met les points sur les i* (he is dotting his *i*'s).

IAMBUS, in prosody; a foot of two syllables, a short and a long one. In Latin, the iambic verse consists of four, six, or (in the comic writers) even of eight feet. The odd feet, i. e., the first, third, and fifth, may be iambs, spondees, anapæsts, dactyles, or tribrachs, (but never trochees). The even feet, however, or the second, fourth, and sixth, must be iambs. The more iambs there are in the verse, the more beautiful it is considered. An iambic verse of four feet is called a *quatrenarius*; one of six, a *senarius*; one of eight, an *octonarius*. The German language, having a prosody, has, of course, the iambus, and makes great use of it in poetry. The iambic metre is also the fundamental rhythm of many English verses.

IAR; a Russian word, signifying *bank*, and appearing in many geographical names; as, *Iaroslaf*, bank of the Slavonians.

IARBAS. See *Dido*.

IBARRA, JOACHIM, printer to the king of Spain, was born at Saragossa, and died Nov. 23, 1785, fifty-nine years old. He raised the art of typography to an excellence before unequalled in Spain. From his press were issued magnificent editions of the Bible, the Mozarabic Missal, Mariana's History of Spain, Don Quixote, and the Spanish translation of Sallust. The latter, which appeared in one folio volume, in 1772,

was made by the Infant don Gabriel, and is very rare, as the prince distributed the whole edition among his friends. Ibarra invented an ink, which, without doing injury to its blackness, he could make thicker or thinner at any moment. He also introduced into Spain the art of smoothing the paper after it was printed. As he never left his country, he invented almost all the improvements which he introduced.

IBERIA, in ancient geography ;—1. a very fertile district in Asia, which consisted of a large plain, surrounded on all sides with mountains, a part of the present Russian Georgia. In ancient times, this country probably belonged to the Persian monarchy; at least, this seems to be intimated by the name of the river Cyrus. Alexander and his successors did not penetrate into Iberia. The Iberians, probably, therefore, remained independent till Pompey and Trajan reduced them to the Roman dominion, under which they remained till after the time of the emperor Julian. They were afterwards subject, sometimes to the Turks, sometimes to the Persians, or had their own princes. 2. Spain was anciently called *Iberia*, and the principal river, *Iberus* (Ebro). The Iberi or Iberians, probably the most ancient European nation, driven towards the West, formed the basis of the population of Italy, Gaul, Spain, and Lusitania. Their language still lives in the Basque. The Celts, who entered the country later, were intermingled with them, and have been considered as the original inhabitants of Spain. See *Celts*.

IBERUS. See *Ebro*.

IBEX (*capra ibex*). This animal is distinguished by large knotted horns, reclining backwards; a small head; large eyes; a thick, short, strong body; strong legs; very short hoofs; and a short tail. Its body is of a deep brown colour, with a mixture of hoary hairs; its belly is of a tawny white; its legs partly black, partly white; the space under the tail, in some individuals, is tawny, in others white. The hair is harsh, and the male is furnished with a beard. These animals are seldom found, except in the most precipitous and inaccessible heights of lofty mountains, where they assemble in flocks, sometimes consisting of ten or fifteen individuals. During the night, they feed in the highest woods, but, at sunrise, they again ascend the mountains, till they have reached the most perilous heights. They are remarkably swift, and display amazing agility and dexterity in leaping. They are objects of the chase, but, from the inaccessible nature of the places to which they generally resort, their dexterity in leaping, and the danger attendant on a pursuit of them, the ibex hunter must have a head that can bear to look down from the most tremendous precipices without terror, address and sure-footedness in the most difficult passes, and also much strength, vigour, and activity. Another danger attendant on this chase is, that the ibex, when close pressed, will sometimes turn on his pursuer, and tumble him down the precipices, unless he has time to lie down, and permit the animal to pass over him. The ibex will mount an almost perpendicular rock of fifteen feet, at three successive bounds, appearing merely to touch it, to be repelled, like an elastic substance striking against a hard body. The fore legs being considerably shorter than the hinder, enables these animals to ascend with more facility than to descend, and hence, when pursued, they always attempt to gain the summits of the mountains. They inhabit the chain of mountains extending from mount Taurus, between Eastern Tartary and Siberia. In Europe, they are found on the Carpathian and Pyrenean chains, and in the Grisons and other parts of the Alps. The season for hunting them is during August and September, when they are usually in good condition. The old males haunt more elevated spots than the females

and younger animals. Their voice is a sharp, short whistle, not unlike that of the chamois, but of shorter duration; sometimes, and especially when irritated, they make a snorting noise. The female seldom has more than one young one at a time: to this she pays great attention, defending it with courage and obstinacy. As to the stories of their throwing themselves down the steepest precipices, and contriving to fall on their horns, when closely pursued, or hanging by these appendages over gulfs by a projecting tree till the danger be passed, we must confess that they appear to us very problematical.

IBIEM (*Latin*); in the same place (generally contracted, as *ibid.*); used for references.

IBIS; a genus of birds found in all parts of the world except Australia, but more particularly in warm climates. Generic characters:—beak arched, long, slender, thick at the base, and quadrangular, rounded at the tip, which is obtuse; nostrils linear, extending from the root to the tip of the beak, and dividing it into three portions, of which the upper is the broadest, and flattened; head and throat bare; legs longish and four-toed, the front webbed at their base as far as the first joint, the hind toe very long, all provided with claws; that of the middle toe, in some, smooth, in others, serrated on its inner edge. The ibes perform a powerful and elevated flight, extending their neck and legs, and uttering a hoarse croak. The *I. falcinellus* (Tem.) is nearly two feet in length, and varies much in its plumage at different ages. This species builds in Asia, and is found on the streams and lakes, in flocks of thirty or forty. They migrate periodically to Egypt, and, arriving there later than the white ibis, stay also later. In their passage, they are numerous in Poland, Hungary, Turkey, and the Greek Archipelago. They occasionally visit the banks of the Danube, Switzerland, and Italy, and, more rarely, England and Holland. The white ibis (*I. religiosa*, Cuv.) arrives in Egypt about the time that the inundation of the Nile commences, its numbers increasing or diminishing with the increase or diminution of the waters; and it migrates about the end of June, at which time it is first noticed in Ethiopia. This species does not collect in large flocks: Savigny has observed not more than eight or ten together. They are about the size of a fowl; the head and neck bare; the body white: the primaries of the wings tipped with shining, ashy black, among which the white forms oblique notches; the secondaries bright black, glossed with green and violet; the quill-feathers of the tail white. These two species are the birds which were adored by the ancient Egyptians, and of which numerous mummies are found. It is remarkable that, with the excellent description of the white ibis, given by Herodotus, before their eyes, naturalists so long gave the name of that bird to individuals which are totally different. The bird described by Perrault as the *ibis blanc*, by Brisson as the *ibis candida*, and by Linnaeus as the *tanaisius ibis*, and considered by these naturalists to be the present species, differs from it in size, and in having the ridge of the beak rounded, its tip slightly grooved on each side, and the nostrils at the root. Consequently it is not an ibis; for in this bird, the beak is not grooved, and the nostrils extend nearly from the base to the tip of the beak. The ibis feeds upon insects, worms, testaceous animals, and sometimes on small fish, and not, as has been said, on snakes. The scarlet ibis (*I. rubra*) is found in the hottest parts of America in large flocks, and frequently the old are separated from the young birds. They fly rapidly, but rarely, except at morning and evening, in search of food. The plumage is scarlet: beak naked; part of the cheeks, legs, and feet, pale red. Before the scarlet ibis reaches its full age, its

plumage varies remarkably. It is a very splendid bird. It sometimes appears in the Southern States of the Union. Other species are found in India, Madagascar, cape of Good Hope, and Mexico. The Greek and Roman writers contain many fabulous stories relating to the ibis, which it would be superfluous to repeat. Savigny, in his learned work—*Histoire Naturelle et Mythologique de l'Ibis*—examines all the questions connected with this subject. His chief hypothesis is, that the ibis did not, in point of fact, destroy snakes, but that the reverence attached to it by the Egyptians arose from its return into their country with the Etesian winds, at the commencement of the season of abundance. The ibis mummies have been found in great numbers in the excavations in Egypt.

IBRAHIM; the Turkish for *Abraham*, and the name of many sultans and grand viziers distinguished in Ottoman history. Among them was Soliman's grand vizier, born in Genoa, of the family of the Giustiniani, and carried by pirates to Constantinople. He was strangled in 1536, at the instigation of Roxelana. (See *Soliman*.) Ibrahim Pacha, the eldest son of the present pacha of Egypt, was born about 1795, commanded an expedition to Sennaar and Dongola, and, in 1825 led the Egyptian forces against Candia and the Morea. He desolated the Morea, until the battle of Navarino, in 1828, put a stop to his devastations. See *Greece*.

IBYCUS; a Greek lyric poet, contemporary with Anacreon, in the middle of the sixth century before the Christian era, and, according to the general account, a native of Rhegium in Italy. He went to Samos during the reign of Polycrates over that island, and passed the rest of his life there. It is related, that, while on a journey, he was surprised and murdered by robbers. Finding escape impossible, he declared that the cranes, which happened to be flying over their heads, would revenge his death. The robbers afterwards, in Corinth, seeing a flock of cranes, one of them said ironically, "See the avengers of Ibycus." These words were heard by a bystander, who reported them to the magistrates. The robbers were in consequence seized, and, after confessing their crime, were executed. Ibycus is said to have left seven books of lyric poetry, in the Doric dialect, and to have invented the musical instrument called the *sambuca*, with a kind of poetry, in which he sung his own life, and which was called, after him, *Ibycean*. Only a few fragments of his works have come down to us. The death of Ibycus is the subject of Schiller's beautiful ballad *Die Kranich des Ibykus* (the Cranes of Ibycus).

ICARUS. See *Dædalus*.

ICE; every frozen liquid; in a more limited sense, frozen water. As soon as the temperature is need, the solid state again gives way to the liquid. We see, then, that ice is nothing but water deprived of its caloric. (q. v.). The freezing of water is a phenomenon so remarkable, that the greatest naturalists have thought it worthy of a careful investigation. Expose a glass, filled with water, to a degree of cold producing ice; an extremely thin film of ice is observed first on the surface of the water in contact with the cold air. Slender threads of ice are soon seen to shoot out from the sides of the vessel, generally forming with it obtuse or acute, seldom right angles; from these rays, new ones continually shoot out, till the whole surface is covered with a single coating; while this process is going on, a great number of air-bubbles arise, as in boiling, which pass out of the water when the congelation is slow; but when it is sudden, they are frozen in, and by their expansion cause rents in the ice. Although cold generally produces contraction, ice occupies a larger

space than water; it is hence specifically lighter, and floats upon it. Those persons are in an error, who suppose that *ground-ice*, as it is called, rises from the bottom of the water after freezing. A kind, however, called *anchor-ice*, appears to be formed at the bottom, or, at least, under the surface, of rapid rivers, perhaps owing to the comparative slow motion of the water at the bottom of a stream. It is well known, that stagnant water freezes sooner than flowing water: perfect rest, however, seems to be unfavourable to freezing, for we know by experience, that water perfectly still is not frozen when its temperature is reduced much below the freezing-point; but a little agitation is sufficient to change it into ice. Sea-water, and in general all salt water, freeze with greater difficulty, because the salt and other ingredients retain the caloric longer. Salt is, moreover, separated in the process of freezing, and precipitated to the bottom, so that ice from sea-water sometimes affords potable water. Salts, however, produce a degree of cold beyond the freezing temperature, and, by means of them, we can cool water much below the freezing-point, while it still remains fluid. Most salts have this property; especially nitre, muriate of ammonia, and common salt. A degree of cold sufficient for the freezing of water may be produced by them in summer, or even over a fire. Artificial ice is formed, also, by exposing pure water, in proper vessels, to such freezing mixtures. The more severe the cold, the greater the hardness and firmness of the ice; and the ice of the polar regions can hardly be broken with a hammer. In the severe winter of 1740, a house was built at Petersburg, from the ice of the Neva, 52½ feet long, 16½ wide, and 20 high; and notwithstanding the enormous weight of the roof, which was likewise of ice, the lower parts of the building did not receive the smallest injury. The pieces of ice were hewn to the form and shape required, adorned and arranged according to the rules of architecture. Before the palace stood six cannons of ice, which were turned on a lathe, with the carriages and wheels of ice, and two mortars formed like cast pieces. The cannons were six-pounders, which are commonly loaded with three pounds of powder; these, however, were loaded with only a quarter of a pound, and carried a ball of stuffed hemp, and sometimes of iron. The balls, at a distance of 60 paces, passed through a board two inches in thickness: the ice of the cannons could not have been much more than three or four inches in thickness, and yet it resisted the force of the explosion. The ice which obstructs the navigation of the arctic seas, according to professor Leslie, consists of two kinds; the one produced by the congelation of fresh, and the other by that of salt water. The snow on the islands or continents, being melted in summer, forms collections of fresh water, which soon freezes, and increases yearly, until the mass becomes mountainous, and rises to the elevation of the surrounding cliffs. The melting of the snow, which is afterwards deposited on these enormous blocks, likewise contributes to their growth, and, by filling up the holes and crevices, renders the whole solid. When such a mass has reached the height of 1000 or 2000 feet, the accumulated weight, assisted by the action of the ocean at its base, plunges it into the sea, and it is driven southwards by the winds and currents, and known to mariners under the name of *iceberg*. The icebergs consist of a clear, compact, solid ice, with a bluish-green tint. From the cavities in them, the northern whalers fill their casks with pure fresh water. The other kind is the field-ice, or frozen sea-water, which is porous, incompact, and imperfectly diaphanous. It consists of spicular shoots or thin flakes, which detain within their interstices

the stronger brine. This ice never yields pure water, but if the brine be first drained off, the icy mass will yield a brackish liquid, which may sometimes be drunk. Sea-water usually congeals at about 27° of Fahr. Within the arctic circle, the congelation begins by the first of August, and a sheet of ice, perhaps of an inch thick, is formed in a single night. In a short time, the whole extent of the polar seas is covered with a vault several feet thick. As soon as the summer heat commences, it is softened, and, with the first swell of the ocean, breaks up, and the fields of the saline ice are thus annually formed and destroyed. The whalers call a large expanse of saline ice a *field*; one of smaller dimensions, a *floe*; when a field is much broken up, it is called a *pack*. If the ship can sail freely through the floating pieces of ice, it is called *drift-ice*. A portion of ice rising above the common level is called a *hummock*, being produced by the crowding of one piece over another. The *ice-blink* is a whitish appearance in the horizon, occasioned by fields of ice, which reflect the light obliquely against the atmosphere. Much ice is exported from Boston to the West Indies and the Southern States of the United States. The exportation began in 1805, and has been increasing ever since. In 1819, when ice was scarce in the neighbourhood of Boston, a vessel was sent to the coast of Labrador, in order to take ice from an iceberg, and succeeded, though with some damage, in procuring a cargo, which she carried to Martinique.

*Artificial Ice.* The Greeks and Romans used various means to preserve snow and ice to cool their drinks; still they never carried this art to such perfection as the moderns have done. We are now better acquainted with the means of producing artificial cold. Experience teaches us, that cold arises from the evaporation of liquids. With vitriolic ether, and still better with nitric ether, artificial ice may be produced in this way, in the middle of summer, and on the warmest days. Ice is formed in the East Indies, in Calcutta, and other places, principally by evaporation. In the level countries there, snow and frost are never known; but in order to have cooling materials in the heat of summer, the inhabitants collect snow and ice, during the winter, from the high mountains, and throw portions of it into small earthen pans, unglazed, which at sun-down are filled with water. The pans are inserted in the earth, two feet deep, covered with dry straw, and evaporation is then suffered to go on. In clear weather, so much caloric is absorbed from the remaining water by this evaporation, that, with the help of the snow floating in it, the whole becomes ice; this is then put in deep caves before sunrise, and preserved for summer. About the middle of the sixteenth century, the custom of cooling drink with saltpetre was introduced into Italy. Afterwards, the method of increasing the cold of snow and ice by a mixture of saltpetre became common. The preparation of artificial ice gradually became more usual; and what was at first only an experiment, at length became an object of luxury. In the beginning of the seventeenth century, ice-cups were introduced, and fruits frozen in ice were brought upon the tables. Soon after, the French began to freeze the juices of all savoury fruits for desserts.

ICELAND, an island in the Atlantic ocean, on the confines of the polar circle, between lat. 63° 23' and 66° 33' N., and lon. 13° 15' and 24° 40' W., area about 40,000 square miles, is supposed by many to be the Ultima Thule of the Romans. About A. D. 860, Naddoir, a Norwegian pirate, was driven on the coast. Gardar, a Swede, circumnavigated it in 864. Floke, a Norwegian, remained on it two winters, and gave it its name from the quantities of ice which drifted

into the bays. The first Norwegian colony arrived there in 874. Christianity was introduced in 981, and formally adopted in 1000. In 1261, the islanders submitted to the king of Norway.

Iceland affords the spectacle of a peaceful, religious, and even literary society, existing for centuries under all the disadvantages of soil and climate. In its physical structure, the action of fire is every where evident. No stratified rocks have been seen, nor any of which the igneous origin is generally contested. Lava covers a large portion of the island. The interior of Iceland (not less, perhaps, than 26,000 square miles) is a dreary waste, only partially known to the natives, who are sometimes obliged to explore it in search of lost sheep, for the most part presenting only a dark surface of lava, without any trace of vegetation. In the south are extensive tracts of melted rock, through which rents, 100 feet wide, extend for several miles. Above these wilds are lofty mountains, with volcanic rocks, protruding through eternal snows. The glaciers or *gætlar* cover a great part of the island. The most extensive is that called *Klofa gætlar*, behind the mountains of the east coast, forming, with little interruption, a chain of ice and snow mountains, supposed to fill a space of 3000 square miles. The progressive movement of the glaciers is observed here as well as in Switzerland, and the moraine, or rampart of debris, heaped together by its descent, has been seen, in some places, 60 feet high, and composed of large rocks. The Snæfell, by a late survey of the island, is found to be 6862 feet high, and is supposed to be the loftiest mountain on the island. Most of the high mountains are slumbering volcanoes. Hot springs and boiling fountains are found every where. The volcano of Krabla, between 1724 and 1730, poured forth streams of lava, which covered several square leagues. In 1755, Katlegiaa, on the eastern shore, burst forth with tremendous fury. The eruption was accompanied with earthquakes so violent, that the people thought the destruction of the island at hand. The detonations of the mountain were heard 30 leagues, and showers of ashes fell on the islands of Ferøe, 100 leagues distant. Fifty farms were destroyed, and rocks of pumice-stone and lava, carried down into the sea, formed promontories extending three leagues from the shore. These rocks still project above the sea, where formerly were 40 fathoms of water. In 1783, an eruption from mount Skeidra covered with lava some of the best districts of the island; the clouds of ashes impregnated the air with noxious particles; the waters were corrupted, the fish driven from the coasts, and famine and pestilence ensued. The miseries which succeeded this eruption destroyed, in two years, 9000 people (a fifth part of the population), with 28,000 horses, 190,500 sheep, and more than 11,000 head of cattle. The eruptions of mount Hecla are rather numerous than violent. The last took place in 1823. The height of Hecla is 5310 feet. Some of the low mountains are covered with coarse grass, affording summer pasturage for the cattle; but the only permanently occupied spots are along the shore. The rivers are numerous and of considerable size, especially on the northern side. There are also many lakes in the interior. Springs or jets of boiling water are frequent: those named the *Geyssers* are most famous, perhaps on account of their accessibility. They are about 30 miles N. N. W. of Hecla, in a plain covered with hot springs and steaming apertures. The Great Geyser rises from a tunnel-shaped basin, lined and edged with siliceous depositions. The pipe at the bottom, from which the jet issues, is about 10 feet in diameter, and the basin, at its outer edge, is about 56. The

eruptions generally take place at intervals of six hours, preceded by a rumbling noise or loud report, like that of artillery, with an agitation of the ground. The column, as measured by a quadrant, has been seen to rise as high as 212 feet. The hot springs near the inhabited parts are used for economical purposes; food is dressed over them; and, in some places, huts are built over small fountains to form steam-baths. In other parts of the island are seen caldrons of boiling mud, emitting sulphureous exhalations. Pestilential airs have been known to issue from particular spots in the plains, during the volcanic eruptions, which have destroyed all who approached. Mineral springs, of many kinds and every temperature, are found; some, highly impregnated with carbonic acid gas, are called by the people *ale springs*, having, it is said, the power of inebriating. Iron and copper are found, but the mines are not worked, for want of fuel. The only mineral from which the people derive a revenue is sulphur, of which the supply appears to be inexhaustible. Extensive mountains are incrustated with it to the depth of some inches. Fossil-wood, impregnated more or less with bitumen, is found in abundance, and might afford valuable stores of fuel to the people, if they had more activity. It is called *surturbrand*, and is used chiefly in the smithies, and in small quantities. Basaltic columns are seen in many places.

The winter, though unsettled, is perhaps less severe than in Sweden and Denmark. The mercury in the thermometer rarely sinks to zero, and the medium temperature of the winter months is, perhaps, not much below the freezing point; the atmosphere is generally clear, and the long nights are cheered by the *aurore borealis*. The floating ice, from the coast of Greenland, has a great effect in increasing the cold, and brings with it polar bears, which commit great ravages on the flocks and herds. From November to February, the people hardly stir from their houses, which are nearly buried in snow. In July and August, the thermometer often stands at eighty or ninety degrees, but sharp frosts frequently succeed the most sultry days. The vegetable productions are comparatively few. Many varieties, however, of moss and lichens are found. In the forests, the birch trees hardly reach the height of ten feet; with these are mingled several varieties of the willow, and a few solitary individuals of the *pyrus domestica* and mountain ash. The bogs are covered with coarse grass.

The Icelanders may be looked upon as a fair specimen of the ancient Scandinavians, having probably undergone less change, for nearly a thousand years, than any other European nation. They are generally tall, with no peculiar physical characteristic, except, perhaps, the length of the spine. The following cut represents their costume.

Their countenances are open, their complexion fair, their hair light coloured, and rarely curled. Corpulency is rare. The houses differ only in size. An outer wall of turf, about four feet and a half high, often six feet thick, encloses all the apartments. On one side, generally that facing the south, are three or more doors, for the most part painted red. These open into the dwelling-house, the smithy, dairy, cow-house. The door of the house opens into a long, dark, narrow passage, from which apartments branch on each side. Each chamber has a separate roof, and is lighted by a small pane of glass, or, more commonly, of amnium, four or five inches in diameter. The thick turf walls occupy more space than the apartments which they enclose. The damp smell which proceeds from them, with the darkness, the filth, and the stench of fish, renders these dwellings insupportable to strangers. Several families sometimes live in the same mass of turf. All the members of the family sleep in one apartment, which is also the general eating room. The kitchen is the only room in which a fire is kept. The women are unceasingly employed. The servants are generally orphans, or the children of poor farmers, and often marry with the children of their masters. The diet of the people is very simple. They eat great quantities of butter, generally in a rancid state; when this is scarce, tallow is used. They breakfast on sour milk. The flesh of the shark or sun-fish is sometimes eaten, when it has become tender from putrescence. Fresh meat, rye bread, and sago soup are holiday fare. The richer inhabitants, however, are not unacquainted with wine, London porter, and other foreign luxuries. To a stranger, the most palatable and healthful article of Iceland diet is the *lichen Islandicus*, now much in vogue as a specific for the consumption. Turf is general fuel; drift-wood and *surturbrand* are also used.

One of the chief cares of the Icelander is to lay in provisions for winter; and, next to his flocks and herds, the sea is his chief resource. About the beginning of February, the people of the interior and of the northern districts begin to move, and a great part of the male population migrates to the western and south-western coasts. Many travel over 200 miles to the place which they choose for a fishing station. About the beginning of May, they return, leaving the fish, not yet perfectly dried, to the care of some one residing on the spot. The best salmon abound in all the rivers. The cow, the horse, and the sheep are the principal sources of wealth, comfort, and subsistence to the Icelander. The sheep are of a peculiar kind, mostly horned; some have only two, others three, four, and upwards. They are milked, as well as the cows, twice in every twenty-four hours. The wool is not sheared, but left to fall off spontaneously. The women pick, clean, and spin it. The cows give ten, twelve, or even twenty quarts of milk per day. The horses are small, but well formed and active. The poorest peasant has four or five. Every one can shoe his horse; even the bishop and the chief justice are sometimes seen thus employed. In 1770, three reindeer were brought from Norway, and have greatly multiplied. Herds of 50—100 are frequently seen. They are not used for domestic purposes, and are very difficult to kill. Hogs and goats are rare. The dogs resemble those of Greenland. There are two kinds of foxes, the white or arctic (*canis lagopus*), and the blue fox (*C. fuliginosus*). The lower orders of the people have a superstitious reverence, mingled with aversion, for the seal. On the west coast, this animal is taken for the sake of its fat. Aware of its observant and inquisitive disposition, the people kindle fires to attract it to the shore, and nets are spread to take it. Sometimes these animals are met at a considerable distance

up the country, being attracted by the lights in the houses. They are easily tamed, and, if young, are put into ponds and fed daily. They soon become as tractable as a dog. In June, the eider ducks visit the coast to nestle. (See *Eider Duck*.) They are so familiar as to build their nests all round the roofs, and even inside the houses. A severe penalty is inflicted on those who kill them. The down which the bird takes from her breast to cover her eggs is removed twice, and even three times, during the season. Swans are numerous in the lakes and marshes. Their down and feathers bring in a good revenue to the people. The tern, ptarmigan, golden plover, and snipe are common. The shores are frequented by myriads of sea fowl. Cod, haddock, ling, skate, and halibut are taken on the coast. Herrings visit the north coast in extensive shoals, in June and July, and are caught in large quantities. The cod is the principal object of the trade with Denmark. Previous to the discovery of Newfoundland, the British were largely engaged in the Iceland cod-fishery, and had 150 vessels so employed at the beginning of the 17th century. At present it is carried on wholly by the Icelanders. The haddock forms a very large share of the food of the inhabitants. Mechanical industry is much hindered by the want of good timber and fuel. The jaws and ribs of whales are, in some parts of the island, used in the frames of houses and boats. The quantities of drift-wood from the west are amazing. The inhabitants of the fiords, in which it is chiefly collected, are the carpenters, coopers, and boat-builders of the island. The hot springs in the Borgar fiord enable them to give the boards the requisite pliancy. The staple exports are fish, oil, feathers, sulphur, and salt mutton; the imports are wood, salt, tobacco, coffee, iron, and fishing-tackle. During the last war between Great Britain and Denmark, the people of Iceland suffered much, their usual supplies of hooks, cordage, grain, &c., being cut off.

The Icelanders are a remarkably grave and serious people, apparently phlegmatic, but extremely animated on subjects which interest them. Vice and crime are hardly known among them. To their religious and domestic duties they are strictly attentive, and, in their dealings with others, display a scrupulous integrity. There are very few of them who cannot read and write, and many among the better class would be distinguished, by their taste and learning, in the most cultivated society of Europe. Perhaps there is no country in Europe in which the lower orders are so well informed. The traveller is often attended by guides who can converse with him in Latin.

The brilliant period of Icelandic literature was from the eleventh to the fourteenth century. A printing-press was introduced in 1530, by a Swede named Mathieson. The first types were of wood, and rudely formed, but before the end of that century, several valuable publications appeared, displaying remarkable typographical elegance. In 1779, an Icelandic society was instituted at Copenhagen, comprising 130 of the most learned and intelligent men of the island. It was dissolved in 1790. Another was established in the island in 1794, with 1200 members. The society have published two books of Thoriakson's translation of Milton's *Paradise Lost*. The remainder has not been printed. A complete copy of this translation, which is said to be the best version of this great poem in any language, was procured by Mr Henderson. The Icelanders have also translations of Pope, Young, and several other English writers. Several schools appear to have existed in the eleventh century. The only school on the island at present is at Bessetad. But

the instruction of his children is one of the regular occupations of the Icelanders, who finds a zealous assistant in the pastor of the parish. The ecclesiastical code of the country allows the clergy to prevent any marriage where the female is unable to read. The amusements of the people are chiefly literary. In all their social meetings, the repetition of poetry, and the reading of the *sagas* or histories, constitute the chief entertainment. The reformation was introduced in 1551, and at present there is no religious dissension among the natives. The inhabited part of the island is divided into 184 parishes. The island forms one bishopric. Every clergyman keeps a register, showing the moral and religious state of his parish. Three thousand copies of the Icelandic Bible were printed by the British and Foreign Bible Society, in 1813, for gratuitous distribution in the island.

The government, as in other Scandinavian nations, was originally aristocratic. When the island became subject to a foreign power, the distinctions of rank gradually disappeared. The governor of Iceland is generally a Dane, appointed by the king of Denmark. The royal authority has not, at present, any constitutional check, but is exercised, nevertheless, in a mild and paternal way. The supreme court of judicature is held annually at Reikiavik. An appeal is permitted, in all cases, to the courts at Copenhagen. The laws are chiefly grounded on the ancient code, called *fonsbok*, compiled in 1280. The civilization of the Icelanders is in nothing so remarkable as in the completeness of their legislation. Trial by combat was abolished in 1001, and punishment for witchcraft in 1690, nearly thirty years before a similar improvement was made in the laws of Great Britain. In case of capital conviction, the criminal is sent to Norway to undergo his sentence, as it is not easy to find an executioner among the Icelanders. The taxes paid are very trifling, and perhaps exceeding 50,000 rix dollars. The laws respecting the maintenance of the poor are very strictly enforced. There are no hospitals except for lepers, who are, unfortunately, common. The sick, aged, and infirm, are, therefore, billeted on the farmers, who are obliged to give relief to their kindred within the fourth degree of consanguinity. Hospitality is a prominent virtue.

Iceland was formerly more populous than at present. The history shows that the climate has been gradually growing more severe and the soil more ungrateful. There is a considerable excess in the female population, and the longevity of the women is greater than that of the men, owing to the greater hardships of the latter. In 1804, the farms amounted to 4751, the horned cattle to 20,325, the sheep to 218,818, the horses to 26,524. Reikiavik, the chief place of the island, is the seat of the governor, the episcopal see, the supreme court, and is the principal mercantile station. It contains about 550 inhabitants. About fifteen miles from the south coast are the Vestmanna islands, fourteen in number. Only one of them, Heimsey or Home island, is inhabited. The inhabitants (only 160) support themselves by fishing and bird-catching. In 1627, some Algerine corsairs carried off the occupants. Those who survived were ransomed in 1636, but only thirteen persons regained their native island.

See the translation of Olafsen and Povelsson's *Travels in Iceland* (published in Paris, 1802, 5 vols., 8vo); *Letters on Iceland*, by Von Troil (London, 1780); *Travels in Iceland* in 1810, by Sir G. S. Mackenzie (Edinburgh, 1811); *Journal of a Residence in Iceland*, by E. Henderson (Edinburgh, 1815). For the literature, see Mallet's *Introduction to the History of Denmark*; Schlozer's *Fragmenta of*

*Northern History*; Fin Johnson's *Hist. Eccles. Islandica*; and Eichhorn's *Alg. Geschichte der Literatur*.

ICELAND MOSS. See *Lichen*.

ICE PLANT (*mesembryanthemum crystallinum*). This singular plant has received the above appellation from the little transparent vesicles which cover its whole surface. The stems are herbaceous, as large as the little finger, spread upon the ground, and very much ramified; the flowers are white, and, as in the rest of the genus, furnished with a great number of linear petals, which give them the appearance of compound flowers, though belonging to a very different family. It is a native of the sea-coast of South Africa, the Canaries, and is also found in the vicinity of Athens. The other species of *mesembryanthemum*, upwards of 300 in number, forming one of the most numerous and remarkable genera of plants, are, almost without exception, confined to South Africa, and constitute a marked feature in its vegetation.

ICETAS; tyrant of Leontini, who caused the sister and wife of Dion, who had fled to him for protection, to be thrown into the sea. He was called in by the Syracusans against the tyrant Dionysius, whom he defeated. But his ambitious designs induced the Syracusans to have recourse to the Corinthians, under Timoleon (q. v.), who defeated Ictas (346 B. C.), forced him to resign his power, and renounce his league with the Carthaginians. Having again taken arms against Timoleon, he was captured and put to death, with his wife and children.

ICHNEUMON (*Aerpestes*, Illig.) These animals belong to the civet family, and are distinguished from their kindred genera by their narrower and more pointed muzzle; by the shape of their lower lip, and, more especially, by the absence of the double cavity beneath the tail, which is replaced by a single pouch, of considerable size, but destitute of secreting glands. Their hair is long, brittle, and generally variegated in colour. The ordinary colour of its coat is chestnut brown and fawn; nose and paws, deep chestnut or black. It is about eighteen inches from the snout to the root of the tail. The habits of the ichneumon are very similar to those of the ferret. In the countries where they are found, their sanguinary disposition and predatory habits render them a great annoyance to the inhabitants, from the destruction they cause among the poultry. This is, however, compensated, in some degree, by the incessant war they wage against reptiles, the eggs of which they devour with great avidity. The most celebrated species inhabits Egypt and the adjacent countries, where it is called *Pharaoh's rat*. It is very common in the northern parts of Egypt, between the Mediterranean and Sion. It is of a grey colour, and has a long tail, terminated by a black tuft; it is larger than a cat, but formed like the weasel. This species was ranked by the ancient Egyptians amongst their numerous divinities, on account, it is supposed, of the benefits which it confers on man by the destruction of crocodiles, whose eggs it digs out of the sand and sucks. The story of its overcoming these formidable reptiles themselves, by gliding down their throats, is, of course, a mere fable. Many other fabulous stories are related of the ichneumon by the Greek and Roman writers, Herodotus, Elian, Diodorus, Pliny, &c. The ichneumon is exceedingly expert in seizing serpents by the neck, in such a manner as to avoid any injury to themselves. Lucan alludes to this (in lib. iv. 724), in speaking of the asp. The ichneumon is domesticated and kept in the houses in Egypt, and is more useful than a cat in destroying rats and mice. They grow very tame, are exceedingly active, springing on their prey with great agility. They often

squat on their haunches, and feed themselves with their fore-paws, like a squirrel. They are great enemies to poultry, and will often feign themselves dead till their prey comes within reach. Like the cat, they are great lovers of fish. When they sleep, they bring their head and tail under their belly, and appear like a round ball. Their voice is very soft, somewhat like a murmur, and, unless they be struck or irritated, they never exert it. Their great disadvantage, as domestic animals, is their unconquerable predilection for poultry, which they destroy whenever they have an opportunity, for the purpose of sucking their blood. In a wild state, they swim and dive in the manner of an otter, continuing beneath the water for a great length of time, and support themselves by fishing. These animals are short-lived, but grow very rapidly.

ICHNEUMON is also the name of a large genus of insects, belonging to the great order of *hymenoptera*. As the species of this genus are very numerous, so their manners are extremely diversified; but, in the general outlines of their character, they all agree, particularly in their depredations among the insect tribes. In some, the female has a wimple attached to her abdomen, and with this instrument, delicate as it appears, she is capable of perforating the hardest substances. The larvæ of wasps are the devoted prey of these insects, who no sooner discover one of their nests, than they perforate the clay, of which it is constructed, and deposit their eggs within it. Others glue their ova to the skin of a caterpillar, whilst others again penetrate through it, and lay their eggs in its body. In all these cases, the young, as soon as they are hatched, prey on the caterpillar or larvæ, without, however, destroying it at once, as upon the life of its victim that of the spoiler appears to depend. The caterpillar, in fact, seems healthy, until the larvæ of the ichneumon have spun their cocoons, and entered the chrysalis state. We often see caterpillars fixed to a leaf or branch by the threads spun by the ichneumon. These carnivorous insects are of various sizes; some are so small that the *aphis*, or plant-louse, serves as a cradle for their young; others again, from their size and strength, are formidable even to the spider, destroying them with their powerful stings.

ICHTHYOLOGY. This term is derived from *ἰχθυς*, a fish and *λογία*, a discourse. According to the system of Cuvier Ichthyology embraces the FOURTH order of vertebrate animals; or all the extensive class of fishes, consisting of oviparous animals with a double circulation.

Fishes have been used as an article of food from the earliest ages. Aristotle was the first writer who formed them into a distinct class; but we are indebted to Pliny for the earliest accounts of their characters and habits. Nothing of any importance appears to have been written on this branch of natural history, for a long series of years after the time of Pliny, until the publication of *Below's* work, which was printed in 1551, entitled *Histoire des Poissons*, wherein he grouped fishes into four families; namely, cartilaginous flat fishes; flat fishes, which were not cartilaginous; the third was sharks, and their congeners; and the fourth, eels and other fishes with elongated bodies.

In 1554, the work of William Rondelet, professor of medicine at Montpellier, was published, wherein he gave most accurate specific accounts of the animals, but did but little to improve the classification. Shortly after appeared the *Aquatilium Animalium Historia* of Hippolyto Salviani. The taste for the study of Ichthyology seems to have taken its rise at this period. In the year 1638, Aldrovandus published a work on fishes; and Willughby in 1686, pub-

lished the first really scientific work on this subject, which was followed by another by Ray in 1713. Artdi considerably improved this branch of science, but died before the completion of his work, which was adopted by Linneus in his first edition of the *Systema Naturæ*. Passing over various successful writers on Ichthyology, we come to the time of Lacépède, who published five quarto volumes on this subject, from 1798 to 1803; but it is to the celebrated Cuvier that we are indebted for the most perfect arrangement on fishes, and whose method we have adopted.

Fishes have red, cold blood, with cartilages or bones, with fins instead of limbs, and which inspire and expire air, in combination with water, by means of gills, instead of lungs. They can live but a short time out of the water, although eels have been seen on land in fields of pease. At Tranquebar, there are perch which, by means of the sharp points on their fins, climb up the palm trees. (See the article *Fin*.) According as fishes have cartilages, or a bony structure, they are divided into two general classes. The cartilaginous fishes either have or have not a gill-cover. To the latter kind belong the lamprey, the ray, and the shark; to the former, the sturgeon, the porcupine-fish, the sea-needle, the eel, and the sword-fish. The bony fishes are divided into orders, according to the position of the ventral and thoracic or pectoral fins. In the eel-pout, the Baltic dorse and the haddock, the ventral fins are placed before the pectoral; they are directly under them in the bream, the perch, the perch-pike, the mackerel, and the river-perch, and behind them in the salmon, the pike, the herring, and the carp. In the structure of fishes, the fins are remarkable as being the only organs of motion. (See *Fins*.) They consist of bony rays, covered with the epidermis, and attached to certain cartilages or bones which are moved by particular muscles. The tail, with its fin, serves as a rudder, to give the proper direction to the motions of the animal. The first impulse in swimming evidently comes from the tail; the other fins serve to regulate the position of the fish, and to guide him in his different motions. The eel, which has no ventral fins, swims like water-snakes, by moving his whole body in an undulating manner. The muscles of fishes must be distinguished from the fleshy muscles of warm-blooded animals. They consist of white or light coloured layers, with fibres of a thicker texture than those of warm-blooded animals; between these layers there is a white, gelatinous substance, which grows putrid very soon after death. If we look at the organs of sense and the nervous system in fishes, we cannot but remark the extraordinary smallness of the brain in proportion to the size of the body. In man, the brain is 1.23 of the body; in the shark, it is 1.2500, and in the tunny fish, 1.37.400; it is also less solid than in warm-blooded animals, and consists mostly of lumps resembling ganglions. The cerebellum is only a transverse plate, entirely without the structure, which, in higher orders of animals, is called *arbor vitæ*. The nerves of fishes are weaker than those of the higher animals; some of them, however, are such powerful exciters of electricity, that they can give violent shocks; but the power ceases as soon as the nerves are cut. The torpedo, the gymnotus, the electric eel, the Indian-needle, and the electric porcupine fish, are five fishes which appear to be living Voltaic piles; for they have two muscular piles, separated from each other by a membrane resembling a net, and which, at least in the torpedo, lie under the curved cartilages of the large side fins, and are regulated by particular nerves. As to the organs of sense in fishes, those of smelling and seeing appear to be the most perfect. Fishes

smell the bait farther than they can see it, and the shark perceives at an incredible distance the colour of a Negro. Their organs of smell have no connexion with those of respiration; and the water apparently conveys the effluvia affecting the sense of smell much less perfectly than the air; but they have very large olfactory nerves, the ends of which were for a long while taken for the true brain. As to their organs of sight, they have very large eyes, but generally no eyelids; but the epidermis goes directly over the eye, and in the blind-fish appears to have only a slight transparency. The cornea is very flat; immediately behind it usually is the crystalline, which can protrude even through the pupil, so that there is very little room for the aqueous humour. The crystalline of fishes, on the other hand, is nearly spherical, and also of a greater density than that of land animals: it is apparently moved by an organ in the shape of a fan, which proceeds from a knot of several optic nerves. The iris is generally of extraordinary brilliancy, and of a beautiful red or gold colour; the vitreous humour is very small. The organs of hearing are less perfect, although this sense cannot be entirely denied to fishes. Only cartilaginous fishes have an external auditory passage, as the shark and the ray; the fishes with bones are without this external ear. All of them have three winding tubes in their head, which terminate in a bag filled with nervous marrow, and containing three hard bones. This constitutes the whole organ of hearing. That of taste seems to be still more imperfect. Their tongue has not even the *papilla*, and the nerves are branches of those which go to the gills. The respiration of fishes is carried on by means of their gills; these are well known to be vascular membranes, four on each side, fastened to a curved and flexible cartilage. They are connected with the cartilages of the tongue, and with the cranium. In cartilaginous fishes, the gills are within the body like lungs, and a determinate number of external openings lead to them; the lampreys, and that kind called the *nine eyes*, have seven, rays and sharks five of these openings. Several fishes have also a peculiar covering for the gills, and frequently a membrane over them, which can be contracted or extended. It encloses a number of winding cartilages, which are called its *rays*. The gills, as is very evident, can only receive the air which is mixed with the water. What is called the *air-bladder* is, in most fishes, joined by an air-pipe, to the stomach or throat. This is thought to contain nitrogen; but it is certain that it assists their rising in the water. Several fishes, as the loach and gudgeon, breathe also through the excretory duct, as is fully proved. The lung are even discovered when at the bottom of the sea, by the rising of air bubbles. Fishes commonly have no voice; but the father-lasher, the loach, the trout, and some others, give, when pressed, a murmuring sound, in doing which they seem to make great efforts, and tremble all over their body. It is very probable that this sound is produced by the air, violently pressed out of the bladder. The circulation of the blood in fishes is, as might be expected, different from that of the higher class of animals. The heart consists only of one auricle and one ventricle; it receives the blood from the body, and sends it, by a single artery, directly to the gills; it is here provided with oxygen by contact with water, and the air contained in it, and is again received by a number of small vessels, which flow together into the aorta, which distributes the blood over the whole body. The motion of the heart is, in fishes, much more independent of the brain and spinal marrow than in the higher orders, and, for this reason, can continue several hours after the brain and spinal marrow have

been destroyed. The chyle produced by the digestion of fishes is received by absorbing vessels, which terminate immediately in the veins, without going through glands. Although most fishes lay eggs, which are matured and hatched out of their body, there are cartilaginous fishes which are viviparous. That there are hermaphrodites among fishes has been lately proved; for Hume has found in lampreys both spawn and milt. The productive power of fishes is greater than that of any higher animal. In the spawn of the tench there have been counted 38,000 eggs at once; in that of the mackerel, 546,000; and in that of the cod, 1,357,000. The twelfth sign of the Zodiac is called "The Fishes."

# ORDER I.—ACANTHOPTERYGIANS.

This order comprehends by far the most numerous race of fishes. They are distinguished by the spines which supply the place of the first rays of their dorsal fins, or which alone support the first fin of the back, where there are two; in some species, instead of a first dorsal fin, it is represented by a few unconnected spines. The first rays of their anal fins consist of simple spines, and each ventral fin has usually one.

## FAMILY I.—PERCOIDES.

Body oblong, covered with rough and hard scales; operculum or preoperculum, and frequently both, have dentated or spinous margins; jaws, fore-part of vomer, and palatine bones, provided with teeth.

### DIVISION I.—PERCOIDES THORACICI.

Ventral fins inserted under the pectorals. They are all edible, whole-some, and agreeable to the taste.

*Sub-division 1.*—Branchiæ with seven rays; back with two fins, both small and dense, as the pile on velvet.

*Larus granulatus*, pl. 45, f. 14. Preoperculum dentated; bony operculum ending in two or three points; tongue smooth; sub-orbital and humeral in some, slightly dentated; snout devoid of scales; second dorsal fin hardly longer than the first; ventral fins placed on the thorax.

*Pomatomus lacerpicum*, pl. 47, f. 22. Two separate dorsal fins; preoperculum simply striated, and the operculum emarginate; eye excessively large; teeth very small, resembling the pile on velvet.

*Sub-division 2.*—Having two dorsal fins; long pointed teeth intermixed with the small densely set teeth, like the pile on velvet.

### DIVISION II.

With seven branchial rays and one dorsal fin.

*Sub-division 1.*—With seven branchial rays and one dorsal fin; teeth dense as the pile on velvet.

### DIVISION III.

With less than seven branchial rays.

*Sub-division 1.*—One dorsal fin; some species with hooked teeth interspersed among the denser ones.

*Sub-division 2.*—Without interspersed hooked teeth.

*Sub-division 3.*—Six branchial rays; and two dorsal fins.

### DIVISION IV.

With more than seven branchial rays.

## SCA-FAMILY I.—PERCOIDES JUGULARES.

With the throat further forward than the pectoral fins.

## DIVISION V.—ABDOMINAL PERCHES.

Ventral fins placed further back than the pectorals.

*Sub-division 1.*—Ventral fins entirely behind; pelvis separated from the shoulder bones.

## FAMILY II.—MAILED CHEEKS.

Head variously mailed, and protected by several bony processes. Suborbital bones more or less extended over the cheeks, articulating behind with the preoperculum.

*Triple pearl*, pl. 46, f. 2. Teeth dense, as the pile on velvet, in the jaws, placed before the vomer; pectoral fins large, but not so much so as to enable them to fly in air.

*Citharus citharus*, pl. 47, f. 15. Formed nearly like the flying Gurnard, particularly in the head, but destitute of supplementary fins.

*Scorpaena Scorpaena*, pl. 47, f. 30. Head mailed, and roughened and compressed on the sides; body covered with scales; branchiæ with several rays; back provided with a single fin; inferior rays of the pectoral fins, simple, articulated, but not branched.

*Tremaster loricatus*, pl. 47, f. 23. Body much compressed; dorsal fin very high, and united to the caudal.

*Apotus macroratus*, pl. 47, f. 19. Palatine teeth and dorsal fin, as in the scorpioids; rays of the pectoral fins branched; they have a suborbital fin inclining from the cheeks. In the first division of the body is scaly, others possess ordinary pectoral fins, without free rays.

*Gremus confusus*, pl. 47, f. 12. Body above and beneath studded with protuberant horny cones, four on the back and

ten on the abdomen, arranged in a double series, with several smaller intermediate ones.

Intermediate between this and the next family Cuvier places a small oval fish, whose whole body is thickly beset with hill-like protuberances, four on the back and ten on the abdomen, arranged in double series, with smaller intermediate ones. Inhabits the Atlantic.

## FAMILY III.—SCIENOIDES.

Preoperculum dentated; operculum spinous; vomer and palatine destitute of teeth; cranial and facial bones generally cavernous; muzzle more or less gibbous; ventral fins frequently scaly. Some are provided with two, and others with only one dorsal fin.

*Eques Balteatus*, pl. 47, f. 24. Body elongated and compressed; teeth small and thickly set; first dorsal fin elevated, second long and scaly.

*Helinus frenatus*, pl. 47, f. 31. Teeth and opercular pieces, like those of the Dascyllus, the former small and as densely set as the pile on velvet.

*Sub-division 1.*—Two dorsal fins.

*Sciæna equula*, pl. 46, f. 1. Destitute of canini and cirri; spines of anal fin weak.

*Sub-division 2.*—One dorsal fin; with seven branchial rays; preoperculum dentated.

*Sub-division 3.*—With less than seven branchial rays, and an interrupted lateral line.

## FAMILY IV.—SPAROIDES.

Palate destitute of teeth; covered with scales, but none on the fins; muzzle not gibbous, nor bones of head cavernous, destitute of spines on the operculum, and indentations on the preoperculum; pylorus provided with caecal appendages; have never more than six branchial rays. Divided according to the form of their teeth.

*Sub-division 1.*—Sides of the jaws provided with round molars in the form of pavement.

*Pagelus centrodontus*, pl. 46, f. 9. Two rows of small rounded molars in each jaw; front conical teeth slender and numerous; muzzle elongated.

*Sub-division 2.*—Conical teeth on the sides of the jaws, usually in a single range; some of the anterior are drawn into large hooks.

*Sub-division 3.*—Teeth dense and short, as the pile on velvet; head crowded together like cards, around the jaws in some, external row strongest.

*Sub-division 4.*—Teeth trenchant.

## FAMILY V.—MENIDES.

Differing from the former families, in the upper jaw being extremely extensible and retractile, owing to the length of the intermaxillary pedicles, which withdraw between the orbits; body scaly.

*Smaris Vulgaris*. Destitute of teeth in the vomer.

## FAMILY VI.—SQUAMIPENNES.

The soft, and in some instances the spinous parts of their dorsal and anal fins covered with a scaly incrustation. Body usually greatly compressed; teeth long, thin, bristle-shaped, and collected in several close rows like the hairs of a brush.

*Epippus Orbis*, pl. 47, f. 25. Dorsal fin deeply emarginated between its spinous and soft portions; spinous part destitute of scales.

*Holacanthus ciliaris*, pl. 46, f. 20. Preoperculum dentated on the edges, and provided with a large spine at its angle; general form, oval or oblong.

## FAMILY VII.—SCOMBEROIDES.

Scales small, body smooth, caeca numerous, and often united in clusters; with a very powerful tail and caudal fin; first dorsal fin entire, last rays of the second, and those of the anal, detached, forming spinous fins spotted.

*Scomber maculatus*, pl. 46, f. 8. Body fusiform, covered with uniform and small scales; tail with two small cutaneous crests on its sides; a void space between the first and second dorsal fins.

*Xiphias gladius*, pl. 46, f. 11. Snout horizontally flattened, and cutting like the blade of a broad-sword. Sides of tail much carinated; one dorsal fin.

*Cybius lineolatus*, pl. 47, f. 38. Destitute of coraet, and body elongated; compressed; cutting teeth resembling lancets; palatine teeth as thickly set as the pile on velvet.

*Xiphias gladius*, pl. 46, f. 11. Scales extremely small, and having carinae on the sides of the tail; provided with a long enaliform beak, which terminates the upper jaw, being an elongation of the vomer and intermaxillaries, supported at its base by the methmoid, frontals, and maxillaries; branchiæ not pertinated; each of them being formed of two large parallel laminae, with a reticulated surface.

*Zeus faber*, pl. 47, f. 24. Dorsal fin emarginate, its spines accompanied by long slips of the membrane; both dorsal and anal fins having a series of bifurcated spines along their bases.

## FAMILY VIII.—TERNIOIDES.

Body elongated, flattened on the sides; scales very small.

*Sub-division 1.*—Muzzle elongated; mouth cleft, and armed with strong, pointed, cutting teeth; lower jaw advancing beyond the upper one.

*Lepidopus argyreus*. Ventral fins consist of two small scaly plates, body thin, elongated, provided with a dorsal fin, which

extends its whole length; anal fin low, terminating in a well-formed caudal fin; branchiae eight rayed.

*Sub-division 2.*—Mouth small but slightly cleft.

#### FAMILY IX.—THEUTYTES.

Provided with the same armature as the Scomberoides, such as exists on the sides of the tail in some genera, or the horizontal line which is to be found in others. The body in all the genera, is compressed and oblong; mouth small, slightly, if at all, projectile; each jaw provided with a row of cutting teeth; tongue and palate destitute of teeth; a single dorsal fin.

*Acanthurus Delisianus*, pl. 46, f. 19. Teeth notched and cutting; tail provided with a strong moveable spine on each side. In some species, the dorsal fin is very high, and others are provided with a brush of stiff hairs before the lateral spine.

*Nasus unicornis*, pl. 47, f. 32. Sides of the tail armed with fixed trepan blades; teeth conical, front protruding fin a horn above the muzzle; branchiae having only four rays, and three soft rays in the ventral fins; the external skin resembles leather.

#### FAMILY X.—LABYRINTHIFORM PHARYNGEALS.

Part of the superior pharyngeals divided into small irregular laminae, which intercept minute cells, in which water is retained for the purpose of moistening their gills when they quit the water, which they frequently do.

*Anabas testudineus*, pl. 46, f. 28. Labyrinths complicated; third pharyngeals provided with tessellated teeth; body round, covered with strong scales; head broad; muzzle short and obtuse; mouth small; lateral line interrupted at its posterior third; borders of operculum, suboperculum, and interoperculum deeply dentated; preoperculum plain; branchiae five rayed.

*Polcanthus colius*, pl. 47, f. 33. Rays spinous; opercula free from dentations; body compressed, and with four rays in the branchiae; teeth consisting of a narrow row of short and crowded; no teeth in the palate; pylorus with two caecal appendages.

#### FAMILY XI.—MUGILOIDES.

Body nearly cylindrical, covered with large scales, and provided with two separate dorsal fins, the first of which have only four spinous rays; ventral fins inserted a little behind the pectorals.

*Mugil Cephalus*, pl. 46, f. 25. Head depressed, broad, scaly; mouth having fleshy crenulated lips; lower jaw with a central carination, entering into a corresponding groove in the upper; teeth hardly perceptible; branchial membrane, three rayed.

#### FAMILY XII.—GOBIOIDES.

Dorsal spines thin and flexible.

*Rennius Palmicornis*, pl. 46, f. 18. Ventrals placed before the pectorals, and only two-rayed.

*Gobius lanceolatus*, pl. 47, f. 37. Ventrals united throughout their whole length; body elongated; head of moderate size, rounded; cheeks inflated, and eyes approximated; two dorsal fins, last long.

*Gobioides brownonectii*, pl. 47, f. 27. Differ from the gobius in the union of their dorsals, which form but one; and the body more elongated.

*Callionymus fasciatus*, pl. 47, f. 26. Branchiae with but one aperture, consisting of a hole on each side of the nape; ventral fins placed under the throat and separate, being larger than the pectorals; head oblong, depressed; eyes approximate, and directed upwards; intermaxillaries very protrusile. Teeth small and crowded; without any in the palate; anterior dorsal fin supported by a few setaceous rays, sometimes very elevated; second dorsal fin elongated as well as the anal.

#### FAMILY XIII.—PEDICULATA PECTORALES.

Pectorals supported by the elongation of the carpal bones. Skin naked; pectorals supported by two arms, each of which are provided with two bones, which correspond to the radius and ulna in the mammalia, but which, in reality, belong to the carpus. Ventrals placed very far before the pectoral fins, opercular and branchiostegous rays enveloped in the skin; only opening in the gills, situated behind the pectorals.

*Lophius piscatorius*. Head disproportionately large, broad, depressed, and spinous; mouth deeply cleft and furnished with acute teeth; lower jaw having numerous cirri; two dorsal fins; branchial membrane forming a large sac, opening in the axilla, and supported by six large rays; operculum small; each side having but three branchiae.

*Chironectes neogallicus*, pl. 47, f. 21. Head with four rays, the first slender and frequently terminating in a tuft; succeeding ones augmented by a membrane, are sometimes greatly enlarged, and at others, united into a fin; head and body compressed; mouth vertically cleft; branchiae with four rays, have only one opening behind the pectoral fin; the dorsal fin occupying nearly the whole range of the back; body entirely covered with cutaneous appendages.

#### FAMILY XIV.—LABROIDES.

Body oblong and scaly; a single dorsal fin supported in front by spines, each having a membranous appendage; jaws covered by fleshy lips; three pharyngeals, two upper ones attached to the cranium, lower one large, all of them provided with tessellated or laminiform teeth.

*Labrus vittatus*, pl. 46, f. 33. Body oblong; lips double and fleshy, one adhering close to the jaws, and the other to the suborbitals; branchiae crowded with five rays; maxillary teeth

conical, middle and anterior ones longest; pharyngeal teeth arranged as if paved, the upper ones in two plates, the lower in a single one corresponding to the two others.

Opercula and preopercula destitute of spines or dentations, cheek and operculum scaly; lateral line straight or nearly so. *Epibulus indidiator*, pl. 47, f. 28. Mouth very protrusile, which by a see-saw motion of their maxillaries is produced into a tube form, with which they capture their prey.

*Xirichthys (Yassirostris)*, pl. 47, f. 29. Body much compressed, front suddenly deepening towards the mouth, in nearly a vertical line, formed by the ethmoid bone and the ascending branches of the maxillaries; body covered with large scales. Lateral line interrupted; jaws with conical teeth, ventral ones longest; pharynx having hemispherical teeth.

#### FAMILY XV.—FLUTE-MOUTHS.

Ethmoidal and adjacent bones produced in the shape of a tubular mouth in front of the cranium; the mouth formed by the intermaxillary, maxillary, and mandibular bones.

*Pistulirus (Chinensis)*, pl. 46, f. 15. A single dorsal fin, which as well as the anal, is composed of simple rays; intermaxillaries and lower jaw provided with small teeth; between two lobes of the caudal fin proceeds a filament which is frequently as long as the body; snout long and depressed. *Centropomus undulatus*, pl. 47, f. 6. Anterior dorsal fin, with the spine, strong, placed far back, and supported by an apparatus connected with the head and shoulders; skin covered with small scales, and also some broad and dentated plates.

#### ORDER II.—ABDOMINAL MALACOPTERYGIANS.

The ventral fins are suspended to the under part of the abdomen, and situated behind the pectorals, but not attached to the shoulder bones.

#### FAMILY I.—CYPRINIDÆ.

Mouth but slightly cleft; jaws weak, generally without teeth, and bordered by the intermaxillaries, by strongly toothed pharyngeals; branchial rays small; body scaly; destitute of an adipose dorsal fin.

*Cyprinus auratus*, pl. 47, f. 11. Mouth very small, jaws destitute of teeth, as also of the flat rays of the branchiae; tongue smooth; palate with a highly irritable substance; dorsal fin long, in which, as well as the anal fin, the second ray is formed of a stout spine. Some of the species have cirri at the angle of the upper jaw.

*Cyprinus carpio*, pl. 46, f. 17. Olive green above, and yellowish beneath; with strong dentated dorsal and anal spines.

#### FAMILY II.—ESOCÆ.

Destitute of an adipose fin; edge of the upper jaw usually formed by the intermaxillary, and when not so, the maxillary is devoid of teeth, and concealed in the thickness of the lip; with the exception of the Microstomus the dorsal and anal fins are opposite each other.

*Esoctus colitans*, pl. 47, f. 8. Pectoral fins excessively large, capable of supporting them in the air: head and body scaly, a salient line formed by a longitudinal line of cartilagenous scales, on each flank; head depressed and compressed, on the sides of the head a fin placed above the anal; eyes large; intermaxillaries constituting the whole range of the upper jaw, and destitute of pedicles; both jaws are provided with small pointed teeth, pharyngeals with teeth set like pavement.

#### FAMILY III.—SILURIDÆ.

Completely destitute of true scales, skin quite naked, or with large osseous plates; intermaxillaries suspended under the ethmoid, forming the edge of the upper jaw: maxillary simple vestiges, or extended into cirri. Intestinal canal simple, destitute of caeca, bladder large; first ray of dorsal and pectoral fins, with strong spines; and like the salmon, frequently with an adipose fin behind.

#### FAMILY IV.—SALMONIDÆ.

Body scaly; first dorsal fin having two soft rays, followed by a second adipose, formed of a cuticle filled with fatty matter, and destitute of rays: they have numerous caeca and a natatory bladder. Structure of jaws subject to much variety.

*Salmo salar*, pl. 47, f. 1. Edge of upper jaw principally formed by the maxillaries, which have a series of pointed teeth, as also in the intermaxillaries, palatines and mandibulars, that on the vomer, tongue, and pharyngeals double. Ventrals opposite the first dorsal, and the adipose opposed to that of the anal. Generally ten branchial rays. Body usually spotted. Flesh wholesome in all the species, and second rivers to seawater.

#### FAMILY V.—CLUPEÆ.

Destitute of an adipose fin; jaws formed by intermaxillaries, having no pedicles in the middle, and by maxillaries on the sides; body scaly; most species have a natatory bladder, and many caeca. Some of the species ascend rivers.

*Clupea pilchardus*, pl. 47, f. 4. Maxillaries arcuated before, and divisible in several longitudinal pieces; opening of the mouth moderate; upper lip not margined.

*Engraulis encrinchus*, pl. 46, f. 2. The mouth cleft considerably behind the eyes; branchial opening large, and surrounded with numerous rays about somewhat pointed, under a tube are attached the intermaxillaries, protruding in front of the mouth; maxillaries straight and elongated.

ORDER III.—SUB-BRACHIAN MALACOPTERYGIANS.

Ventrals placed under the pectorals; pelvis directly suspended to the shoulder bones.

FAMILY I.—GADITES.

Ventrals pointed and attached to the throat; body slightly compressed; scaly; head scaleless; fins soft; jaws and front of vomer with pointed teeth, set in several rows, resembling a rasp; branchiae large, seven-rayed: most of the species have three fins on the back; one or two situated behind the anal opening and a distinct caudal fin.

FAMILY II.—FLAT-FISHES.

Head devoid of symmetry; both eyes on one side, which is always uppermost: two sides of the mouth unequal; body much compressed; dorsal fin generally extending along the whole back, and the anal occupies the under part, appearing as if a continuation of the ventral, which are often united with it. Some of the species have their head reversed from the ordinary law.

*Pleuronectes Cornarius*, pl. 46, f. 12. A range of cutting teeth in each jaw, usually appearing as if paved in the pharyngæ; dorsal fin extending the length of the eye. An interval between the caudal and dorsal, as well as between the anal. Generally rhomboidal, eyes placed on the right side.

*Solea Zebra*, pl. 46, f. 24. Mouth oblique to the opposite side to that in which the eyes are placed, that side only provided with minute thick-set teeth; snout rounded, projecting beyond the mouth; dorsal fin commencing at the mouth, which, with the anal fin extends to the caudal; lateral line straight; general form oblong.

FAMILY III.—DISCOBOLI.

Ventral fins forming a disk.

*Cyclopterus lumpus*, pl. 47, f. 18. First dorsal fin more or less visible, but very low; rays simple; a second branchial ray opposite the anal fin.

*Echeneis Remora*, pl. 45, f. 16. Head provided with a depressed disk, composed of transverse laminae, directed obliquely backwards, posterior edge dentated; body elongated and scaly; a small soft dorsal opposite the anal; mouth horizontally cleft and rounded; lower jaw projecting beyond the other, intermaxillaries with teeth resembling those of a card; a range of delicate teeth skirt the maxillaries; anterior edge of the vomer with small teeth like a card.

ORDER IV.—APODAL MALACOPTERYGIANS.

There is but one natural family in this order. The species are of an elongated form; skin thick and soft scales in consequence nearly invisible; bones few.

FAMILY I.

*Anguilla conger*. With pectoral fins and branchiae opening under them on either side; dorsal and caudal fins continued round the end of the tail.

*Optidium tetraodon*, pl. 46, f. 10. Dorsal and anal fin united with that of the tail, and terminating the body, which is much elongated and compressed, so much so that it resembles a sword in a point; scales very small, and planted in the thickness of the skin.

ORDER V.—LOPHOBANCHIATE FISHES.

Jaws perfect and free; gills in place of being like the teeth of a comb, are divided into small tufts; arranged in pairs along the branchial arches. They are enclosed beneath a large operculum, fixed down on both sides by a membrane, which exhibits only a small orifice for the exit of the water, and showing in its thickness vestiges of rays only; scutellated plates of mail cover their body, which is usually of an angular shape.

*Synbranchius acus*, pl. 47, f. 3. Snout tubular, formed like the flute-mouths, by an elongation of the ethmoid, vomer, tympanum, preopercula, and other bones, terminated by an ordinary mouth, almost vertically cleft. Respiratory opening near the snout; devoid of ventral fins.

*Hippocampus foliatus*, pl. 47, f. 10. Trunk laterally compressed, and considerably more elevated than the tail. Joints of scales raised into ridges, and their salient angles into spines. Tail destitute of fins.

*Pegonius Draco*, pl. 47, f. 16. Snout salient; mouth under its base; body mailed, as in the Hippocampus; trunk broad, depressed. Branchial apertures placed on the sides; two distinct ventral fins behind the pectorals, which are frequently large, whence the name of the genus.

ORDER VI.—PLECTOGNATHES.

Maxillary bone permanently attached to the side of the intermaxillary, by which the jaw is alone constituted, and in the manner in which the palatine anal is united by its suture to the cranium, and consequently destitute of power of motion. Opercula and rays concealed under a thick skin, through which only a small branchial fissure is visible. They have no true ventral fins.

FAMILY I.—GYMNODONTES.

In place of teeth a small ivory substance, internally divided into laminae, which, in their aggregate, resemble a parrot's bill. Opercula small, five rays on each side, all nearly concealed.

*Diadon Histris*, pl. 47, f. 17. Jaws undivided, formed of one piece above, and another below; behind the cutting edges of which, a round transversely furrowed portion, acting as an instrument of mastication; skin provided with pointed spines, resembling, when inflated, the burr of a chestnut tree.

*Tetraodon hispidus*, pl. 46, f. 4. Jaws divided in the middle by a suture, presenting the appearance of four teeth, two above and two below; spines small and low.

*Cephalus brevius*, pl. 46, f. 5. Jaws undivided; body compressed, and destitute of spines; incapable of inflation; tail so short and high, that its posterior termination appears as if cut off: dorsal and anal fins, both high and pointed, and are united to the caudal. Skin with a thick layer of gelatinous substance spread under it.

FAMILY II.—SCLERODERMES.

Mouth conical or pyramidal, projecting from the region of the eyes, and terminating in a small mouth, provided with a few distinct teeth in each jaw. Skin generally rough or provided with hard scales.

*Balistes aculeatus*, pl. 46, f. 22. Body compressed; each jaw containing eight teeth, in a single row, generally cutting; skin scaly, or covered with thickest granulations, but not osseous; first dorsal fin with one or more spines, articulated with a bone which is attached to the cranium; the second dorsal fin long, soft, and placed opposite to an anal one, which is nearly similar.

*Ostracion auritus*, pl. 46, f. 21, and *Ostracion turritus*, pl. 47, f. 13. Head and body covered with bony plates, in place of scales, soldered together, forming an inflexible shield; the only movable parts being the tail, fins, mouth, and a small lip with which the edge of the gills is provided; all of which pass through orifices in the coat of mail by which they are invested. The vertebral column is also soldered together. Each jaw provided with ten or twelve conical teeth; external branchial aperture, a small slit, provided with a cutaneous lobe. Destitute of both pelvis and ventrals; a small single ventral and dorsal fin only.

CHONDROPTERYGIANS.

Several of this division approach in their formations to the reptiles, in the conformation of their auditory and genital organs. In some, the organization is so simple, and the skeleton so greatly reduced, that they hardly deserve a place among vertebral animals. They therefore constitute a series somewhat similar to the first, in the same manner as Marsupial animals, bear a similitude to the hoofed Mammalia.

The skeleton is essentially cartilaginous, containing no osseous fibres, the calcareous matter being deposited in small grains, and not in filaments; consequently they are destitute of sutures in their cranium, which is always formed of a single piece.

ORDER I.—STURIONES.

Gills with a single wide opening, and provided with an operculum, but destitute of rays in the membrane.

*Acipenser huio*, pl. 46, f. 27. Body covered with bony plates, set in a series of longitudinal rows, and mailed on the exterior portion of the head; the mouth is small and toothless, situate under the snout; the palatine is affixed to the maxillaries, and inserted into the upper jaw, the vestiges of the intermaxillaries forming part of the thickness of the lips. The mouth being placed on a pedicle, is more protractile than that of the shark; eyes and nostrils placed on the side of the head, and there are cirri inserted under the snout; no appearance of external ear: a spherule behind the temple leads to the branchiae. Dorsal fin situated behind the ventrals, and the anal fin under it; the caudal fin surrounds the extremity of the spine, and is provided with a salient lobe beneath.

*Callorhynchus Australis*, pl. 46, f. 26. Snout terminated by a fleshy, hoe-shaped appendage; the second dorsal fin commences over the ventrals and terminates at the front part of the fin attached to the tail.

ORDER II.—FIXED GILLED CHONDROPTERYGIANS.

Organs for the escape of water pierced in the skin, sometimes terminating in a common duct, through which the water is transmitted; little cartilaginous arches are frequently suspended in the muscles opposite to the external edges of the branchiae, and which may be denominated branchial ribs.

FAMILY I.—SELACPHI PLAGIOSTOMI.

Palatines and post-mandibulars, only, provided with teeth, and supply the place of jaws, which are represented by mere vestiges of bone; their apparent jaw suspended by a single bone to the cranium, which represents the tympanal, jugal, and temporal bones, and also the preoperculum: a hyoid bone affixed to this pedicle, and supports the branchiostegal rays, as in ordinary fishes, although hardly visible externally; followed by the branchial arches, but neither compose the operculum. Provided with both pectoral and ventral fins, the latter on the abdomen, placed on each side of the anal opening.

*Squalus Zygaena*, pl. 46, f. 8. Snout prominent, with nostrils placed beneath, but neither in a prolonged furrow, nor provided with lobules, having a lobe on the underside of the caudal fin approximating to the bifurcated form.

*Pristis antiquorum*, pl. 46, f. 7. elongated with the body flattened before, and the branchial opening situated below, as in the rays; having a very long, depressed, sword-shaped snout,

armed on each side with strong, bony, cutting, and pointed spines, planted like teeth. The teeth of the mouth resemble small paving stones.

*Torpedo perloni*, pl. 46, f. 10. Disk of body nearly circular, anterior border formed by two productions of the snout, side-wise inclined, so as to reach the pectoral fins; head and branchial filled with honeycomb-like tubes, subdivided by horizontal diaphragms, into little cells filled with mucus. It is in this apparatus in which the galvanic power resides. Tail short and fleshy.

#### FAMILY II.—SUCTORII CYCLOSTOMI.

The suckers are the most imperfect of all vertebral animals as regards the skeleton: they are destitute of both pectoral and ventral fins; body elongated, terminated before by a fleshy lip and cartilaginous ring. Annular portion of the vertebræ, not cartilaginous throughout its whole circle: destitute of ordinary ribs; branchial ones much developed, and united to each other, but devoid of solid branchial arches: the branchiæ resembling purses, resulting from the junction of one part of a branchium with the opening of that contiguous: ear enclosed by the cranium; nostrils with a single orifice.

*Petromyzon marinus*, pl. 47, f. 5. With seven branchial openings on each side; skin of tail, above and beneath, turned up into a longitudinal crest, supplying the place of a fin; maxillary ring provided with strong teeth; interior disk of lip very circular, provided with tubercles, and covered with a hard shell. This ring is supported under a transverse plate, and seems to supply the want of intermaxillaries, vestiges of maxillaries may be seen on the sides of these. Tongue provided with two longitudinal rows of small teeth, which move backwards and forwards in the manner of a piston; a dorsal fin before the anal opening, and another behind it, which unites with the tail fin. *Gastrobranchius carus*, pl. 47, f. 2. Intervals of the branchiæ communicate with a common canal on each side; each of which terminates in a distinct perforation situated under the heart.

**ICHTHYOLITE** (*Greek*), means, in mineralogy, a petrified fish, or a stone with the impression of a fish upon it.

**ICHTHYS** (*ἰχθυς*, *Greek* for fish); a word found on many seals, rings, lamps, urns, and tombstones, belonging to the earliest Christian times. Each character forms an initial letter of the following words: *Ιησους*, *Χριστος* *Θεου* *Τις* *Σωτης*; that is, *Jesus Christ*, the Son of God, the Saviour. The picture of a fish is also sometimes engraved in similar works, having a mystical meaning. The latter may have merely originated from the word *ἰχθυς*, and this again from the initials of the above-mentioned words; but it is much more probable that the ancient Christians gave to the image of the fish, (so much revered as a religious symbol among most ancient nations) a mystical meaning. It was natural enough that nations who expressed all their religious and scientific conceptions symbolically, should adopt a fish as an emblem. On account of its immense fertility, the fish was emblematical of the great fructifying power of nature; and, as many kinds of fish indicate, by certain motions, the changes of weather, it became an object from which the priests prophesied; hence it readily became sacred to them. The fish was worshipped by the Syrians, Assyrians, Phœnicians, and the Western Asiatics in general.

**ICOLMKILL**, or **I-COLUMB-KILL**; one of the Hebrides, called by the Monkish writers **IONA**. Its original name, by which it is still known in its vicinity, was *I*, signifying *island*; but, St Columb having founded a monastery there, it came to be called **I-COLUMB-KILL** (the island, Columba's Cell.) It is two and a half miles in length by one in breadth, and is separated from Mull by a channel about half a mile wide. Icolmkill is chiefly interesting to the antiquarian from the views of its ancient religious edifices. These were established about the year 565, by St Columb, who left Ireland, his native country, with the intention of preaching Christianity to the Picts. The remains of these edifices, almost all constructed of sienite, together with crosses and sepulchral monuments, are the antiquities now extant. The exact date of none of the former is known, but the church is said to have been built by queen Margaret, towards the latter end of the eleventh century. It is built in the form of a cross, 164 feet long without,

and 34 broad; the body of the church is 60 feet in length, and the two aisles of the transept, or cross, are each 30 feet long, and 18 broad within the walls. The east window is a beautiful specimen of Gothic workmanship. In the middle of the cathedral rises a tower, 22 feet square, and between 70 and 80 feet high, supported by four arches, and ornamented with bass-reliefs. Here are the tombs of forty-eight Scottish kings, four kings of Ireland, eight Norwegian monarchs, and one king of France. The cell of Icolmkill became the mother of 100 monasteries; the princes and nobles of Scotland were sent thither for education, and it was the favourite sepulchre of the Scotch and Irish kings. The island is described by Mr Pennant, doctor Johnson, and other travellers. See *Hebrides*.

**ICON** (*ἰκον*), an image.—*Iconolatry*; adoration of images.—*Iconoclasts* (q. v.); breakers of images.—*Iconography*; the representation of statues, busts, household gods, mosaic works, and pictures in water-colours. Michael Angelo and Ursinus were the restorers of this art, which was carried farther by John Angelus Canini and Bernard de Montfaucon. Canini published his *Iconography* at Rome, in 1669 (1 vol., 4to), and Montfaucon the *Antiquités Expliquées*. The latest work of this kind is Visconti's *Iconographie Ancienne* (Paris, 1808—17, 4 vols., 4to); it contains the portraits of the princes and celebrated men of antiquity. Three volumes form the *Iconographie Grecque*, the following the *Iconographie Romaine*; the fifth volume was published, in 1821, by A. Monges; the sixth volume concludes the whole. Also the *Iconographie des Contemporains, depuis 1789, jusqu'à 1820*, by Delpech (Paris, 1824, thirty numbers, each with four portraits and a fac simile), has met with great success. The *Iconographie du Règne animal*, by Guérin, was published at Paris (1829).

**ICONOCLASTS**; that Christian party which would not tolerate images in the churches, much less the adoration of them. This dispute began in Greece, and extended from thence over Europe; it was most violent in the eighth and ninth centuries. In the three first centuries after Christ, the Christians had no paintings or images in the churches. The first cause of the Christian worship of images was partly, the custom of erecting columns in honour of the emperors, with their statues, partly the attempt to preserve the memory of the bishops and the martyrs by images. In the fourth, and still more in the fifth century, they were placed in the churches, yet without receiving any adoration; but in the sixth century, people began to kiss the images, in token of respect, to burn lights before them, to offer incense in honour of them, and to ascribe to them miraculous power. Some bishops endeavoured to dissuade Christians from this worship of images; others tolerated them as becoming decorations of the church; while others, in their reverence for them, approximated to complete idolatry. The Eastern emperor Leo III., the enemy of superstition and the worship of images, issued an edict, in 726, ordering the people to remove from the churches all the images, except that of Christ, and to abstain entirely from the worship of them. This order occasioned commotions, first in the islands of the Archipelago; and, as the popes Gregory II. and III. admitted of the worship of images, and the emperor Leo refused to recall his edict on their command, they excommunicated him, and his subjects in Italy threw off their allegiance. Thence arose two parties in the Christian church, namely, the *Iconolatra* and the *Iconoclasts*, who have mutually persecuted each other, even to death. Leo's son and successor, Constantine, proceeded with less rigour. He convened a council at Con-

stantinople (754), in which the use, as well as the worship of images, was condemned. Constantine's son, Leo IV., who ascended the throne 773, followed the same course; but his wife, Irene, caused him to be poisoned, in 780, and a council at Nice, in Bithynia, restored the worship of images (786), and inflicted punishment upon those who maintained that nothing but God ought to be worshipped. Although the Greeks and Italians were addicted to the worship of images, yet most Christians of the West, as the Britons, Germans, Gauls, did not follow their example; on the contrary, they asserted that it was lawful to retain images, and expose them in the churches, but that they could not be worshipped without offending God. Charlemagne, probably assisted by Alcuin, wrote against the worship of images, and a council which he caused to be held at Frankfurt on the Maine (794) confirmed his opinion, notwithstanding the opposition of pope Adrian. Among the Greeks, the controversy concerning images broke out anew after the banishment of Irene (802), and lasted almost half a century. Her successor, Nicephorus, did not, indeed, remove the images from the churches, but he forbade the adherents of the images from persecuting their adversaries. Finally, the empress Theodora, by a council held at Constantinople, 840, restored the worship of images among the Greeks, which was confirmed by a second council, held, 879, in the same place. In the Western Empire, images were at first retained only to preserve the memory of pious men, but the worship of them was forbidden. This use of them was confirmed by a council summoned by Louis the Debonnaire, in 824; but this opinion was gradually abandoned, and the decision of the pope, which allowed the worship of images, finally prevailed in the Western church. See the following article.

ICONOLATRY (from the Greek *ikon*, image, and *latria*, worship); the worship or adoration of images. The preceding article shows what dissensions the worship of images has produced in Christendom. To Protestants, the respect (whatever it may be called) which the Catholics pay to images is an object of great dislike: they consider it the breach of one of the first commandments of Christianity—to worship in the spirit and in truth—whilst, on the other hand, the Catholics say that malice or ignorance only can ascribe to them the heathen custom of adoring images. Every thing, say they, depends upon the meaning given to the word *adore*. "In vain," says the Catholic writer in the *Dictionnaire de Théologie*, article *Adoration*, "do they (the Protestants) maintain that God alone shall be adored: if they mean by it, *honoured as the Supreme Being*, it is true; if they understand by it, that he is the only being to be honoured, it is a falsehood." He thus continues: "We respect their (the saints') images, because they represent them, and their relics, because they belonged to them; but we do not adore them, if by *adoring* is understood worshipping them like the Supreme." If some Catholic authors, from a careless use of language, have improperly applied the expression *adoration*, this proves nothing, as our creed is clearly exposed in all our catechisms." The Protestants maintain, first, that "none is holy but the Father;" and no gradation in worship can exist; that the mass of men, always being inclined to take the form or sign for the essence, do so also among the Catholics (if we are to suppose the images were not intended for real worship by the church), as all Catholic countries sufficiently prove, by the unrestrained worship and miraculous powers ascribed to images; and, thirdly, that there is a vast difference between the "respect" paid by Catholics to images, and that shown to them by Lutherans, who un-

doubtedly respect the religious paintings in their churches, on account of the subjects represented, but neither pray before them, nor kiss them, nor ascribe miraculous power to them, nor think them essential to religious service. The Calvinists are still more rigid than the Lutherans in regard to paintings and similar ornaments in churches.

ICONONZO; the name of two natural bridges in Colombia, province of Cundinamarca (New Granada), on the road from Santa Fe de Bogota to Ibaque south-east of the village of Pandi. They traverse the river of Somma Paz, which runs in a narrow, deep valley, that would be inaccessible, if it were not for these bridges, which stand one above the other. The most elevated is 325 feet above the river, 2870 feet above the level of the sea, over forty feet wide, and is composed of a solid rock, in the form of an arch; its thickness in the centre is seven or eight feet. The second bridge is more than fifty feet below the other. It appears to be the result of the fall of a part of the rock which formed the first. In the centre is an opening, through which is seen the abyss, and innumerable night-birds hovering above the water, which falls into a cavern so dark that its sides are not distinguishable.

ID., IBID.; abbreviations of *idem*, *ibidem*, the same (author), or at the same place.

IDA in ancient geography;

1. A mountain in the Troad, at the foot of which lay the city of Troy, and whose declivity towards the sea forms the scene of the famous events during the siege of Troy. Its southern part was called *Gargarus*, and one of its highest peaks, *Cotyllus*. On mount Ida was a temple to Cybele, who was called the Idæan mother (*Idæa mater*). Here Paris ended the strife between the three goddesses, and gave to Venus the prize of beauty; here Ganymede was seized and carried to Olympus; and in general, mount Ida was the scene of many Grecian fables. It produced a great number of pines, and was famous for its pitch.

2. A mountain in the island of Crete, or, more properly, the middle and highest summit of the chain which divides the island from east to west. The eastern part was called *Dicte*, the western *Leuci* (*albi montes*). This highest peak, particularly called *Ida* (now *Pailoriti*), has at its foot a circumference of 600 stadia. This peak terminates in two rocky summits, almost always covered with snow and ice. It affords, from its height, a fine prospect, and is covered with woods of pine, maple, and cedar, but it is not very fertile. Among the few plants which grow upon this mountain is the *tragacantha* (goat's thorn). Copious streams flow down its sides, and enrich the neighbouring summits. The first inhabitants of Crete dwelt in its caves, and iron is said to have been first found there. Mount Ida is famous as the birth-place of Jupiter. See *Candia*.

IDEAL; an imaginary model of perfection. In the fine arts, the ideal is distinguished from the exact imitation of reality by avoiding the imperfections which always disfigure the individual, and giving to each excellence its highest perfection. Imagination creates ideals, in the fine arts, by abstractions from individual forms, separating the individual and casual from the general and the essential, and thus produces ideals of a particular kind. If it performs the same process on these, again abstracting the general and essential, it creates new ideals of a still higher kind; and, if this abstraction be carried on further, we arrive at last at the pure ideal, which is incapable of any further separation and generalization—the ideal form of the whole genus. Thus man creates forms elevated above the real forms of nature: we do not say above nature itself, because we under-

stand by nature not only the actual appearances of the sensible world, but also the laws and prototypes which lie at their foundation, and at which imagination arrives in the way indicated. As in thousands of crystals we do not find one which forms a perfect mathematical figure, while the effort of nature to produce such a figure is obvious in all, so is it with the beautiful. All the individual instances may be regarded as the imperfect attempts of nature to produce a faultless model. In creating the ideal of beauty, man does not follow, as some suppose, the arbitrary suggestions of fancy, but strives to discover and present the prototypes of nature. Imagination finds the materials of the ideal in reality, but she unites the separate traits of the grand and the beautiful, dispersed through nature in one perfect ideal. So, too, there may be ideals of the hateful, the horrid, the malignant; for the ideal aims merely at completeness, whether in the good or the bad, the grand or the mean, the graceful or the ugly, the heroic or the ridiculous. Dante often gives us the ideal of physical suffering, whilst the Koran aims to present the ideal of sensual enjoyment. The caricature is, under a certain point of view, an ideal. The characteristic, which is founded on the deviation of the individual form from the generic, is therefore opposed to the ideal, which loses by any deviation from the generic form; but, on the other hand, the representation gains in character, and thus satisfies the claims of the fine arts, which require, not only the beautiful but the true. Truth must in no case be sacrificed to beauty. A medium must therefore be employed, by which the truth may be represented as beautiful. This medium is the true ideal of the imitative arts. Genius only can decide how far the characteristic and the generic are to be mingled. See the article *Copy*.

IDEALISM is the name usually given to that system of philosophy, according to which, what we call external objects are mere phenomena of our own minds. It originated with Descartes. Malebranche went a step further; but bishop Berkeley was the first who sought to prove the non-existence of matter, and is therefore regarded as the founder of modern idealism. See *Berkeley*.

IDENTITY, SYSTEM OF. See *Schelling*.

IDEOGRAPHIC; that way of writing which expresses the ideas and not the sound. Part of the Chinese characters are ideographic; as, for instance, when the sign which signifies *hand*, and some other sign, expressing a material, designate the trade in which this material is made or used: this is *ideographic* writing. See *Chinese Language*, and *Hieroglyphics*.

IDES, or IDUS; with the Romans, the fifteenth day of March, May, July, and October. In the other months, it was the thirteenth, owing to the variation of the nones. (q.v.) These days were sacred to Jupiter, to whom the *flamen dialis* sacrificed a sheep. The *ides* were also sacred to different deities. The *ides* of March, on account of Cæsar's death, was an *ater dies*, and was called *paricidium*. The senate was not allowed to sit on that day. See *Calendar*.

IDIOSYNCRASY (*Greek*) means the peculiar effect produced by certain agents upon the bodily frame; or the peculiar, and, frequently, morbid feeling of liking or dislike which a person has, with regard to certain objects, whether physical or intellectual.

IDIOT (from the Greek *idiotes*, which signified a private citizen); one who took no interest in the general welfare. The modern meaning therefore deviates much from the old one.

IDIOTICON; a dictionary confined to a particular dialect or containing words and phrases peculiar to

a part of a country. There exist in Germany several very valuable *Idiotica*.

IDOCRASE is found most usually in distinct crystals, with the general form of short, square prisms. Their primary form is a right prism, with square bases; and the crystals yield to cleavage parallel to all its planes, with sufficient brilliancy to obtain incidences of 90° by the reflective goniometer in every direction. Lustre, vitreous, inclining to resinous, sometimes very distinctly the latter; colour, various shades of brown, passing into leek-green, pistachio-green, olive-green, and oil-green; streak, white, semi-transparent, or only translucent on the edges. If viewed in the direction of the axis, the colours incline more to yellow; perpendicular to it, more to green; hardness between that of feldspar and quartz; specific gravity, 3.399. It also occurs massive and granular. Idocrase was first found among the lavas of mount Vesuvius, and hence its old name, *Vesuvian*. It was afterwards discovered at Eger, in Bohemia, and being taken for a new mineral, was called *Egeran*. A variety, resembling egeran, has been called *loboite* and *fragardæ*. Another, from Tellemarken, in Norway, of a blue colour, and containing copper, has been called *cyprine*. Idocrase has yielded by analysis the following results (the two first were obtained by Klaproth, the third by count Dunin Borkowsky):

	Vesuvian from Vesuvius.	Vesuvian from Siberia.	Egeran from Bohemia.
Silica,	35.50	42.00	41.00
Alumina,	33.00	16.25	22.00
Lime,	22.25	34.00	22.00
Magnesia,	0.00	0.00	3.00
Oxide of iron,	7.50	5.50	6.00
Oxide of man- ganese,	0.25	a trace	2.00
Potash,	0.00	0.00	1.00

The varieties from Vesuvius and from Fassa in the Tyrol, easily melt into a dark-coloured globule. The localities of idocrase in Europe are numerous. In the United States, it has been met with, handsomely crystalline, at Worcester, in Massachusetts, of a reddish brown colour, like the egeran of Bohemia; in Newton, New Jersey, also in white limestone, with blue corundum, in large yellowish-brown crystals; and at Amity, Orange county, New York, in white limestone, with augite, spinelle, and brucite.

IDOLATRY. Reason commands us to adore a supreme, infinite, perfect being, whom we call God. Idolatry, however, reveres a false god, an idol, a being which is not God—a finite being instead of the infinite. We learn from history, that the pure idea of the inexpressible Godhead spreads but slowly; for man always seizes the form instead of the substance, and is long in acquiring a purely spiritual conception. This is the case with individuals as well as with whole nations. History teaches us also, that the fear of misfortunes and the desire of happiness have been the chief sources of idolatry. At first, natural causes were unknown to men. They could not explain the growth of fruit, the origin of heat, of light, of the winds, &c. Without the labour of profound investigation, their imaginations created rulers of either sex, to whom they ascribed the direction of all outward events. Thus, some revered stars, trees, stones, springs, &c. Others gave their gods human shapes, and, at the same time, human passions, desires, and wants. Thus anthropomorphism (the representation of the Deity with human qualities, either actual or symbolical) took its origin. Men endeavoured to gain the favour of God, as they did that of their fellow men, by offerings and prayers. Each nation had its particular god, who was not the

common father of all men, but its own tutelary divinity, and so had every tribe, family, and even individual. The image of this tutelary god had its place in the house, and became the god of a house, of a man, or of a family. His presence and power were limited to the place of his residence: he became the protector and counsellor of him by whom he was chosen. The god of the hunter and of the warrior became the god of hunting and of war. The god of the shepherd took care of the herds, and the god of the husbandman became the patron of agriculture and the bestower of fruitful seasons. Those divinities required particular ministers, whose duty it was to regulate their worship, to bring before them the wishes of men, and return their answers to the suppliants. This office, selfish cunning turned to its own advantage. Individuals pretended to a familiar intercourse with the gods: thus originated prophecies and oracles. Many sensible men, even in the most ancient times, were, however, convinced of the folly of all this, and were led to the idea of one God.

**IDOMENEUS**; son of Deucalion, and grandson of Minos, king of Crete. He was remarkable for his beauty, and was one of the suitors of Helen; he, however, continued a friend of Menelaus, and often visited him in Lacedæmon. With Merion, he led the Cretans, in eighty ships, to Troy, and distinguished himself by his valour. At the funeral games of Patroclus, he quarrelled with Ajax Oilcus, maintaining that Idomeneus had won the prize in the chariot race, while Ajax claimed it for Eumelus. Achilles ordered them both to be silent, and Idomeneus asserted that Idomeneus had feeble eyesight, through age, whence it appears that he must then have been very old. After the conquest of Troy, he embarked with Nestor, among the first of the Greeks, and, during the voyage, was assailed by a violent tempest. To escape from it, he made to Neptune the rash vow, that he would sacrifice to him the first person whom he should meet. The storm abated, and he arrived happily at the port; but the first person he met was his only son, who had heard of the arrival of his father, and came to welcome him. Nevertheless, Idomeneus sacrificed him. His subjects, who feared the vengeance of the gods upon their land for such a deed, rebelled, and drove him from the island. He went to Italy, and founded the city of Salernum, where he introduced the laws of Minos, and was honoured as a god after his death. According to other historians, he was driven from Crete by Leucus, and went to Colophon, where he died; and was buried on mount Cercaphus. Others, and especially Diodorus, say nothing of the vow, but relate that he returned safely to Crete, where he died quietly, after a long and peaceful reign; that he was buried near Geosus, and received divine honours.

**IDRIA**, a town in Carniola, in the Austrian kingdom of Illyria, so celebrated for its quicksilver mines, lies in a valley surrounded on every side by lofty mountains, covered by thick woods; population, 4139, who are mostly engaged in mining, or in occupations connected therewith. The valley being extremely narrow, the houses stand on the sides of the hill, each with a garden annexed to it, in which the miners raise a few vegetables, notwithstanding the inclemency of the climate and the sterility of the soil. The little river Idrizza, in winter a formidable torrent, runs through the midst. The number of labourers, above and below ground, is stated at 900, exclusive of upwards of 300 wood-cutters, who fell timber in the forests, which they float down the rivers, or prepare in various ways. The annual produce of these mines amounted formerly, for a considerable period, to from 500 to 600 tons of quick-

silver. The greatest part of it used to be exported to Spain, whence it was sent to America for the amalgamation of silver ores; but the revolutions, terminating in the independence of the Spanish colonies, effectually interrupted those dealings, and, as the market for the produce was diminished, the mines of Idria were wrought with less vigour, and the amount now produced is not more than half that above-mentioned. A great part of the quicksilver is conveyed to Vienna, and sold on the account of the emperor. England, it is said, takes the largest share. The mines of Idria have the reputation of being the most magnificent in the world. The galleries and adits are so neat and spacious, that no disagreeable exhalation is perceptible. The entrance is by a lofty, vaulted cavern, conducting to the descents: these are formed by clean stone steps, which are kept in excellent order. The steps have several landing places, paved with broad flags, and provided with benches to rest on. As the miners proceed deeper into the pit, the passages continue to be arched over, and provided with steps. In a very few places, the vault is supported with wood, and occasionally the solid rock is cut through, which, of course, needs no support. The ore is not of uniform richness; some specimens furnish 80 per cent, but the average does not exceed 50. The small quantity of virgin quicksilver that is occasionally found, is shown as a rarity. The principal shaft is 80 fathoms in depth. In the beginning of the present century, the wood-work in the galleries of these mines took fire, and the conflagration raged so obstinately as to threaten the destruction of the whole. The heated, sulphurous exhalations prevented the workmen from approaching the scene of danger, and the flames could not be extinguished until the river was led, by an artificial channel, to discharge itself into the mines. The mines belong to the government, and are wrought entirely at its expense. The district of Idria contains sixty-three square miles, and 10,000 inhabitants, who manufacture linen and laces.

**IDUNA**. See *Northern Mythology*.

**I. E.**; abbreviation of *id est*, Latin for *that is*.

**IFERTEN**. See *Yverdon*.

**IFFLAND**, AUGUSTUS WILLIAM; a celebrated German actor and dramatic writer, born at Hanover, April 19, 1759. His taste for the theatre manifested itself in his infancy, and he was so much affected by the representation of the Rhodogune of Corneille, that his parents would suffer him to be taken to the theatre but very rarely. Nothing, however, could prevent him from indulging his natural inclination; and his father having declared that he would never permit him to be an actor, he left home privately, and made his debut at Gotha, in 1777. The poet Gotter, who then resided in that city, assisted young Iffland with his advice. When this theatre was dissolved, he went to Mannheim, in 1779, and, in 1796, was invited to Berlin, to take the direction of the theatre there, and, in 1811, was appointed general director of all the royal plays. He died Sept. 22, 1814. His autobiography is in volume first of his works. He was no less famous as a writer than as an actor. His first production was a tragedy, called Albert of Thurneisen, which was well received by the public, and was followed by a number of dramatic pieces for the theatre of Mannheim, among which may be mentioned, the Neighbours; Daughters to be married; the Act of Birth; the Idlers; Mr Musard; besides translations from the French of Picard and Duval, and from the Italian of Goldoni. The works of Iffland are very numerous. An edition of them was published under his own direction, at Leipsic, in 1798 (17 vols., 8vo). It comprises, besides forty-seven plays, memoirs of his theatrical career, and reflections on

the theory of his art. Madame de Stael said of him, that there was not an accent or a gesture, for which Iffland could not account as a philosopher and an artist.

**IGNATIUS LOYOLA.** See *Loyola*, and *Jesuits*.

**IGNATIUS, SAINT**; one of the fathers of the church, who suffered martyrdom at Rome, during the third persecution of the Christians. He was a Syrian, and is said to have been an immediate disciple of St John the Evangelist, who, in the sixty-seventh year of the Christian era, committed the church at Antioch to his pastoral superintendence. There he presided for upwards of forty years, when the emperor Trajan, after his triumph over the Dacians, entering the city, exercised many severities towards the Christians, and summoned the prelate himself before him. Ignatius conducted himself with such boldness in the imperial presence, that he was forthwith sent to Rome, and ordered to be exposed in the amphitheatre to the fury of wild beasts. This dreadful death he underwent with much fortitude, having availed himself of the interval between his sentence and its execution to strengthen, by his exhortations, the faith of the Roman converts. Of his works, there remain seven epistles, edited, in 1645, by archbishop Usher, republished by Cotelierus, in 1672, in his collection of the writings of the apostolical fathers, and again printed, in 1697, at Amsterdam, with notes, and the commentaries of Usher and Pearson. An English translation of them, from the pen of archbishop Wake, is to be found among the works of that prelate. There are some other letters, of minor importance, which are generally considered to have been attributed to him on insufficient authority.

**IGNITION** (glowing heat) denotes that state of certain bodies, in which, from being exposed to a high temperature, they appear luminous. Two kinds of ignitable bodies are distinguished; namely, such as become entirely changed by ignition, as charcoal, sponge, &c., and such as retain their former state, as iron, for example. The first is a regular combustion, in which, however, no gas rises from the bodies in the form of flame. The second is a mere heat. Of the metals, many liquefy before they become ignited; for example, lead and tin. Iron, on the other hand, becomes ignited long before it melts. Three stages of ignition may easily be distinguished. Iron, at about 770 degrees of Fahrenheit, becomes brownish red, which is the commencement of ignition. At a higher temperature, it becomes red hot; at about 1000 degrees of Fahrenheit, it becomes white hot, and emits a very white, brilliant light. If gradually cooled, ignition diminishes in the same inverse order. In this gradual transition, we perceive all the different colours of light. Hence the Dynamists conclude that caloric, in ignition, actually combines with bodies, and does not merely penetrate their pores, as the Atomists teach.

**IGNIS FATUUS.** See *Meteor*.

**IGUANA.** These reptiles are thus characterized by Cuvier: body and tail covered with small imbricated scales; the ridge of the back garnished with a row of spines, or rather of elevated, compressed and pointed scales; under the throat, a compressed and depending dewlap, the edge of which is attached to a cartilaginous appendage of the hyoid bone. Their thighs are provided with a similar arrangement of porous tubercles with the true lizards, and their head is covered with scaly plates. Each jaw is furnished with a row of compressed triangular teeth, having their cutting edges serrated; there are also two small rows on the posterior part of the palate. There are many species described by naturalists, most of which are natives of tropical America. They live for the

most part on trees, but sometimes go into the water. They feed on fruits, seeds, and leaves. The female deposits her eggs, which are about the size of a pigeon's egg, in the sand. Many of the species are considered as great culinary delicacies by the natives of the countries in which they are found. The common iguanas (*I. tuberculata*, Laur.) are eagerly sought, especially in the spring. They are caught by means of a noose attached to the end of a stick. The iguana, although formidable in appearance, is timid and defenceless. It is very active, though, when it has taken refuge in a tree, it appears to depend on the security of its situation, and permits itself to be taken by its pursuers. Where the noose cannot be conveniently used, it is struck on the head with a stick and stunned. They attain a great size, being sometimes found five feet in length. The word *iguana* is said, by some authors, to be derived from the Indian *Aisana*, and, by others, to have originated in the Javanese word *leguan*.

**ILDEFONSO, St**; a village containing La Granja, a royal palace of the king of Spain, in Old Castile, built in a mountainous country, by Philip V., in imitation of Versailles; six miles N. E. Segovia, forty N. by W. Madrid. Population, 4887. The exterior of the palace is not very magnificent, but the interior contains a great number of valuable paintings, statues, &c. The gardens are very magnificent, being the chief ornament. The elevation of the palace above the sea is 3789 feet, the highest royal residence in Europe. The castle and gardens of St Ildefonso cost about 45,000,000 of piastres. At this place a peace was signed between the king of Spain and the French republic, August 4, 1795.

**ILI** (Turkish for country); a word appearing in geographical names, as *Roumili* (country of the Romans).

**ILIAD.** See *Homer*.

**ILISSUS**; a rivulet which watered the plain of Attica, and flowed down from the Hymettus (q. v.), laved Athens, and was lost with the Cephissus in the morasses.

**ILITHYIA**; among the Greeks, the goddess who assisted women in childbirth. The name, which some have derived from the Oriental languages, appears to be purely Greek, and to signify *she who comes*. This goddess, when her assistance is required, comes at the third call, and the female is saved. Pausanias says that, not far from the chapel of Serapis, at Athens, a temple was built to Ilithyia, who, coming from the Hyperboreans, had assisted Latona, when seized with the pangs of childbirth, in Delos. The Cretans, on the contrary, believed that Ilithyia was born at Amnisus, in the country of Gnosus, and was a daughter of Juno. Thus there were two Ilithyias, who are to be distinguished from each other. According to Grecian mythology, Juno, the institutress and protectress of marriage, had two daughters—Hebe, or the pure virgin, and Ilithyia, or she who bears. Juno therefore could send or refuse the assistance of her daughter Ilithyia, and is often represented herself as the bringer into light (Lucina), as is evident from the passage in Terence, *Juno, Lucina, fer opem*. According to Horace, in his secular ode, Ilithyia and Lucina were the same. The second goddess of the name was a divinity regarded, in Asia Minor, as the emblem of the creative and all-nourishing power of nature, and her worship spread from Media along the shores of the Black sea to Asia Minor. The image of this goddess, in heaven, was the moon; on the earth, a cow. Her principal shrine was Ephesus, and her worship being confounded with that of the children of Latona in later times, she became the Artemis of the Greeks, and the Diana of the Romans. The number of

*Lithyias* afterwards increased to three, of which two were good, and one evil. All three were, at a later period, called *genetlides*, or *goddesses of childbirth*.

ILLIUM, in ancient geography; the name of two cities, which are distinct from each other:

1. New ILLUM, now known under the ancient name of *Troy*, or the modern name of *Trojahi*, in the territory of Tros, near the influx of the Hellespont into the *Ægean sea*.

2. Old ILLUM, or the celebrated city of *Troy*, so called from Ilius, son of Tros, was situated farther from the coast. See *Troy*.

ILLINOIS; one of the United States of America; bounded north by the territory of Huron, east by lake Michigan and the state of Indiana, south by the Ohio river, which separates it from Kentucky, and west by the Mississippi, which separates it from the state and territory of Missouri. Lat.  $37^{\circ}$  to  $42^{\circ}$   $30'$  N.; lon.  $81^{\circ}$   $20'$  to  $91^{\circ}$   $20'$  W.; 380 miles long, from north to south, and 210 miles wide, from east to west; square miles, 58,000. Population, according to the United States' census of 1830, 157,575, and according to the state census of the same year, 161,055. There are, besides, about 5900 Indians, chiefs of the tribes of the Sacks and Foxes, and the Pottawatomies. The state is divided into forty-eight counties. The capital of the state is named Vandalia. It is situated on the Kaskaskia river, a little south of the centre of the state. The other principal towns are Kaskaskia, Cahokia, Edwardsville, and Shawanetown. The principal rivers, besides the Mississippi, Ohio, and Wabash, which bound the state on the west, south, and east, are the Illinois, Kaskaskia, Little Wabash, Big, Muddy, and Rocky rivers. The sources of the Illinois and Rocky rivers are near those of the streams which empty into Michigan lake, and the country is so flat that, in the wet seasons, the waters of the rivers unite, so that boats pass through them from the Mississippi to the lake. It is proposed to construct a canal, which shall unite the permanently navigable parts of the Illinois with lake Michigan, and, to promote this object, a large grant of land, lying upon the route of the proposed canal, has been made by congress. The southern and middle parts of the state are for the most part level. The banks of the Illinois and Kaskaskia, in some places, present a sublime and picturesque scenery. Several of their tributary streams have excavated for themselves deep and frightful gulfs, particularly those of the Kaskaskia, whose banks, near the junction of Big Hill creek, present a perpendicular front of solid limestone 140 feet high. The north-western part of the territory is a hilly, broken country, though there are no high mountains. The climate is not materially different from that of the same latitudes in the Atlantic states. The low and wet lands, in the southern part, are unhealthy. The cold of winter is sometimes extremely severe. The soil has been divided into six distinct kinds:—1. Bottom lands, bearing a heavy growth of honey locust, pecan, black walnut, beech, sugar maple, buckeye, pawpaw, grape vines, &c. This land is of the first quality, and is found, in greater or less quantities, on all the considerable rivers. It is of inexhaustible fertility, and is annually cultivated without manure. 2. Newly-formed land, found at the mouths and confluences of rivers. It produces sycamore, cotton wood, water maple, water ash, elm, willow, oak, &c. There are many thousand acres of this land at the mouth of the Wabash, and at the confluence of the Ohio with the Mississippi. It is annually inundated, and is unhealthy. 3. Dry prairies, approaching the rivers and bordering on the bottom land, from thirty to one hundred feet higher, and from one to ten miles wide. These

prairies are destitute of trees, except where they are intercepted by streams of water and occasional tracts of woodland. It has been estimated that as much as two-thirds of the whole state consists of open prairie.

The dry prairie has a black rich soil, well adapted to the purposes of agriculture, and is covered with rank grass. 4. Wet prairie, found remote from streams, or at their sources. This is generally cold and unproductive, abounding with swamps and ponds, covered with tall grass. 5. Land covered with timber, moderately hilly, well watered, and of a rich soil. 6. Hills of a sterile soil, and destitute of timber, or covered with stunted oaks and pines. The prevailing forest tree in Illinois is oak, of which as many as thirteen or fourteen different species have been enumerated. Honey locust, black walnut, mulberry, plum, sugar maple, black locust, elm, bass wood, beech, buckeye, hackberry, coffee nut, sycamore, spice wood, sassafras, black and white haws, crab apple, wild cherry, cucumber, and pawpaw, are found in their congenial soils throughout the territory. White pine is found on the head branches of the Illinois. On the Saline river, a branch of the Ohio, are salt springs, from which salt is manufactured at a cheap rate. About 300,000 bushels of salt are made here annually. At Galena, on Fever river, near the north-western corner of the state, are very rich lead mines, from which great quantities of that metal are obtained at a very trifling expense. The working of these mines was begun in the year 1821. In 1824, there were made 175,220 lbs of lead; in 1825, 664,530 lbs.; in 1826, 958,842 lbs.; in 1827, 5,182,180 lbs.; in 1828, 11,105,810 lbs.; in 1829, 13,343,150 lbs.; and in 1830, 8,323,998 lbs. The diminution in the quantity made in 1830, compared with the produce of the preceding year, was occasioned by the great reduction in the price of lead. The quantity of lead received by the United States, in 1830, from the miners, for rents, was 504,214 lbs. The chief produce of the state is Indian corn, wheat, and the other agricultural productions of the Northern States. A few families emigrated from Canada about the year 1780, and settled at Kaskaskia and Cahokia, where their descendants still remain. In 1800, the whole population of the territory, which now forms the state, exclusive of Indians, was 215. In 1810, the population was 12,282; in 1820, 55,211; and in 1830, as we have already stated, 157,575, of whom, at the last named date, 1653 were free blacks, and 746 slaves.

The territory of Illinois was formed into a state, and admitted into the Union, in 1818. The constitution provides, that no more slaves shall be admitted into the state. The legislative power is vested in a general assembly, consisting of a senate and a house of representatives. The senators are chosen for periods of four years, and the representatives for two years. The executive power is vested in a governor, who is chosen for four years, and is ineligible for the next succeeding four years. There is a supreme court established by the constitution, and there are inferior courts established by the general assembly. The judges are appointed by the assembly, and hold their offices during good behaviour, or till removed by the governor, on the address of two-thirds of each branch of the general assembly. One section of land, in each township, amounting to a thirty-sixth part of the township, is granted for the support of schools; and three per cent. of the net proceeds of the United States' lands sold within the state, is appropriated for the encouragement of learning, of which a sixth part is required to be bestowed on a college or university. A further provision has been made for a university by the grant of two townships of land by the United States. A col-

lege has been established at Jacksonville, which is yet in its infancy.

**ILLINOIS**; a river formed by the junction of the Theakiki and Plein, in the north-west part of Indiana, in latitude 41° 48' N. It passes into Illinois, pursues generally a south-westerly direction, and flows into the Mississippi, twenty-one miles above the Missouri. It is upwards of 400 yards wide at its mouth, and is about 400 miles long from its junction to the Mississippi, and is of easy navigation. It has a very gentle current, unbroken by falls or rapids, and passes through a fine country. The Plein, its northern head branch, interlocks with the Chicago, which flows into lake Michigan. A canal has been projected to unite the head waters of the Illinois with lake Michigan, and thus connect the Mississippi and the great lakes.

**ILLUMINATI** (via. the *enlightened*); a secret society, founded in 1776, by Adam Weishaupt, professor of law at Ingolstadt, for mutual assistance in attaining a higher degree of morality and virtue. It contained, in its most flourishing condition, 2000 members, among whom were individuals of distinguished talents and high rank. The constitution and organization were taken partly from the Jesuits, and partly from the masons. By order of the Bavarian government (1784) the society was dissolved. The society had no influence whatever on the French revolution, as has often been said.

**ILLYRIA**. The Illyrians, a nation of kindred origin with the ancient Thracians (mingled with Greeks, Phœnicians, Sicilians, and Celts), were spread over the whole coast on the east of the Adriatic, the neighbouring islands, and Western Macedonia, as far as Epirus. Philip, king of Macedonia, took from them the part of their country extending from Macedonia to the river Drinius (now Drino), and Illyria (Illyricum, Illyrica) was divided into Illyrica Græca and Barbara. The former (modern Albania) was incorporated with Macedonia. It contained Dyrrachium (Durazzo), formerly Epidamnus, where the Romans commonly embarked for Italy, and Apollonia, a Greek commercial city of some importance, with an academy. The latter division extended from the river Arsia (now Arsa), in Istria, to the Drinius, and was divided into Japydia, Liburnia, and Dalmatia. This province obtained distinction in the history of the Roman emperors, several of whom were born here. Piracy was one of the principal means of subsistence of the Illyrians, whose kings, therefore, were frequently embroiled in quarrels with the Romans, which, at last, ended in the subjection of the Illyrians, under their king Teuta, 228 B. C. The savage race sought, indeed, from time to time, to shake off their chains; but being beaten by Cæsar, and greatly enfeebled by Augustus, Germanicus, and Tiberius, the country at last became a Roman province, and, as such, held a high rank. The name, to which, in the fourth century, was added the epithet of *magnum* (great), included almost all the Roman provinces situated in the East. At the division of the Roman empire, Illyria fell to the empire of the West, but, upon its overthrow, in 476, it came to the emperor of the East. In the middle of the sixth century, Slavonian colonists from Russia and Poland settled there, and soon succeeded in rendering themselves independent of the weak Byzantine government. Thus arose the small kingdoms of Dalmatia and Croatia. In 1020, the emperors did, indeed, reconquer these provinces, but twenty years afterwards, they regained their independence. In 1090, the Venetians and Hungarians also made themselves masters of a small part of Illyria. In 1170 arose the Rascian kingdom, from which, 200 years later, that of Bosnia was formed. Dalmatia, at first, was

taken by Venice, but, in 1270, the greater part of it was conquered by the Hungarians, who penetrated to the Black sea. Both they and the Venetians lost nearly all these conquests to the Turks; for the Venetians retained only a small part of Dalmatia, while Hungary kept possession only of Slavonia, and a part of Croatia. The peace of Campo-Formio, October 17, 1797, brought Venetian Dalmatia, and its islands as far as Cattaro, under the dominion of Austria. Twelve years later, Old Illyricum was again restored. "The circle of Villach, Carinthia, what was formerly Austrian Istria, Fiume, and Trieste, the lands known by the name of the *Littorale*, and all that remains to us on the right bank of the Save, Dalmatia, and its islands, shall bear the name of the *Illyrian provinces*." Such was the decree of the emperor of the French, October 14, 1809. This state of things lasted fifteen months, during which Illyria received an addition of 650 square miles, by the junction of a part of Italian Tyrol, ceded by Bavaria; when, April 15, 1811, appeared a decree of the French emperor, definitively organising the Illyrian provinces in their military and financial concerns. The country, independently of its great commercial cities and seaports, which were very important to the navy of an empire such as that of France was to be, had great internal resources. Since 1815, Illyria has been an Austrian kingdom, and, together with the separate kingdom of Dalmatia (q. v.), the chief support of the Austrian navy. In 1825, the circle of Clagenfurt, the territory of Carinthia, together with the province of Laybach, were incorporated with Illyria. The Illyrian Littorale, since 1825, includes, together with the commercial district of Trieste, two circles—those of Goris and Istria. The Istrian government has its seat in Mitterburg. The kingdom of Illyria contains 9,137 square miles, with thirty-five cities, fifty-nine market towns, 7891 villages, and 897,000 inhabitants, mostly Slavonians, Morlachians, and Germans. The people are mostly rude and warlike. (See *Austria*.) The government is divided into two branches, one of which has its seat at Laybach, capital of the kingdom, the other at Trieste. See Russell's *Travels in Germany*.

**IMAGINATION**; the faculty of the mind which forms images or representations of things. It acts either in presenting images to the mind of things without, or by producing those whose originals are not, at the moment, present to the mind or the sense. We therefore distinguish—(1.) original imagination, or the faculty of forming images of things in the mind—that is, the faculty which produces the picture of an object which the mind perceives by the actual impression of the object—from the (2.) reproductive imagination, or the faculty which recalls the image of an object in the mind without the presence of the object. Besides the power of forming, preserving, and recalling such conceptions, the imagination has also the power (3.) to combine different conceptions, and thus create new images. In this case, it operates involuntarily, according to the laws of the association of ideas, when the mind is abandoned to the current of ideas, as in waking dreams or reveries. The association of ideas is either directed to a definite object by the understanding, or it operates only in subjection to the general laws of the understanding. In the former case, the imagination is confined; in the latter, its operations are free, but not lawless, the general law of tendency to a definite end fixing limits to its action, within which it may have free play, but which must not be overstepped. The free and yet regulated action of the imagination alone can give birth to the productions of the fine arts. In this case, it forms images according to ideas. It composes, creates, and is called the *poetical faculty*.

From the twofold action of the imagination, we may distinguish two spheres, within which it moves—the promic and the poetical. In the former, it presents subjects on which the understanding operates for the common purposes of life. Here it is restricted by the definite object for which we put it in action. In the latter, it gives life to the soul, by a free, yet regulated action, elevates the mind by ideal creations, and representations above common realities, and thus ennobles existence. Imagination operates in all classes, all ages, all situations, all climates, in the most exalted hero, the profound thinker, the passionate lover, in joy and grief, in hope and fear, and makes man truly man.

**IMAN, IMAMODE, IMAM;** a class of Turkish priests. It is necessary that they should have studied in Turkish schools, but their acquisitions are generally limited to the power of reading the Koran, and an enthusiastic gesticulation. They attend in the *dedmans* and mosques, call the people to prayer from the minarets, perform circumcision, &c. They are chosen by the people, and confirmed by the secular authority, under whose jurisdiction they also are in criminal and civil affairs. In ecclesiastical affairs, they are independent, and are not subject to the mufti, though he is the supreme priest. They may quit their office and re-enter the lay order. They are distinguished by a wider turban, of a different form from the common ones, and by their sleeves. They enjoy some privileges, and cannot be put to death, without being stripped of their ecclesiastical dignity. A Turk loses his hand, and a Christian his life, if he beats an iman. The sultan, as chief of all ecclesiastical affairs, has the title of *iman*.

**IMARETHI,** in Turkey; houses where boys at schools, and students of the colleges, and the poor, receive their dinner. The Mohammedan government have spent large sums for the establishment of the *imarethis*. In Constantinople, 30,000 people are said to dine in them daily.

**IMACS;** the ancient name of the Himalaya mountains. (q. v.)

**IMBERT, BARTHOLOMEW,** an ingenious French writer, was born in 1747, at Nismes. He was the author of several compositions of merit, both in prose and verse, which obtained a high degree of popularity. Of these the one most favourably received was a poem which has for its subject the judgment of Paris. His fables, written in the manner of Fontaine, are less esteemed. He was also the author of some successful dramatic pieces, and of a novel entitled *Les Egaremens de l'Amour*. He died of an attack of fever, in 1790.

**IMMERISION.** See *Occultation*.

**IMMORTALITY;** the condition of that which is not subject to death. Immortality has a beginning, and thus differs from eternity, which has neither beginning nor end. Eternity is an attribute of God; immortality of some of his creatures, as, for instance, of the soul. The dogma of the immortality of the soul is very ancient. It is connected with almost all religions, though under an infinite variety of conceptions. By the immortality of the soul, we understand the endless continuation of our personality, our consciousness and will. Philosophers have endeavoured, in different ways, to prove the immortality of the soul—the anchor of man's hope amid the storms of life—in modern times, particularly, from the immateriality of the soul. But this immateriality is not susceptible of rigorous proof, and, if it were, it would only follow that the soul need not perish with the death of the body. It might still pass into a state of unconsciousness, as in a deep sleep and a swoon, a state little better than annihilation; yet the idea, that the dissolution of the body

involves the annihilation of existence, is so cheerless, so saddening, that the wisest and best of men, of all ages, have rejected it, and all civilized nations have adopted the belief of its continuation after death, as one of the main points of their religious faith. There are so many reasons to render it probable, which are as convincing to most men as any strict proof could be, that, with most nations, the belief in the immortality of the soul is as clear and firm as the belief in a God; in fact, the two dogmas are intimately connected in the minds of most men. The hope of immortality must be considered a religious conviction. Reason commands man to strive for continued perfection. This duty man cannot relinquish, without abandoning, at the same time, his whole dignity as a reasonable being and a free agent. He must, therefore, expect that a continuation of his better part, as the necessary condition for his progress in perfection, will not be denied to him. Hence the belief in immortality becomes intimately connected with our belief in the existence and goodness of God. The perfection at which man aspires, depends on the continuance of his individuality; and, therefore, he is hardly more startled by the doctrine of the materialist, who denies all difference between the mind and the body, than by the opinion which maintains that after death the soul of man loses its individuality, and is absorbed in the universal spirit. The noblest feelings are called into exercise by objects which affect man as an individual. Love cannot exist without individual objects of affection; and man trembles at the idea, that the purest enjoyments of which he can conceive, shall perish by the extinction of his individual nature. The proofs of immortality which the Scriptures afford, are familiar to our readers.

The views of man, in regard to the nature of his future existence, are chiefly influenced by his ideas of the relation of the body to the soul. As soon as man begins to observe the peculiar operation of the soul, the idea of its existence after death arises, and is supported by the emotions of hope and fear, by many inexplicable phenomena of nature, and even by illusions. At first, this continuation of its existence is conceived of in connexion with that of the body, and with a state of being not essentially different from the present, in which the hunter shall renew his chase, and his corporeal senses shall have their accustomed gratifications. This perhaps is the reason of the careful preservation of dead bodies at an early period. Subsequently, a new and more finely organized body is conceived of, or the soul is represented as of a more aerial substance (hence the name of *spirit*, *air*, or *breath*, is commonly used, in the more ancient languages, to denote the soul); or as a shadow, which, being separated from the body by death, continues its existence by itself. In this case, the life after death is also considered as a shadow of the present, as in the Greek mythology. Whilst the life of the soul was conceived of as connected with the earthly body, or with a new and ethereal body, it became necessary to assign a distinct place, different from that in which we live, for its habitation. The invisible world is conceived of by most nations, at first, as subterranean. In a more advanced stage of the progress of mankind, the imagination attributes changes of condition to the future life, and the doctrine of the metempsychosis, or the progress of the mind, in different stages, is now formed. See *Transmigration of Souls*.

The belief in apparitions, in conjurations of the dead, and the influence of the dead upon the living, is intimately connected with the belief in immortality. The conception of the state of the departed depended, of course, upon the state of civilization, and what was considered as perfection here, was be-

lieved to be enjoyed in the after life, whether this perfection were skill in hunting, or the intellectual enjoyment of knowledge. It was also natural, that the after life should be considered as standing in connexion with this; and thus morality, as well as the belief in the justice of the Ruler of man's destiny, created the belief of a retribution after death, which has also been considered, according to the state of civilization, in all possible gradations, from the coarsest bodily pain to the intellectual pain of exclusion from the presence of God; hence naturally arose the idea of places where this retribution was accomplished—hell and heaven. This idea of a state of retribution, seems to have given rise to the notion of the resurrection of the body. Connected with the belief in the immortality of the soul, is the belief in a state where souls are purified after death, as existing among the Egyptians and the Catholics. (See *Purgatory*.) No religion teaches so pure a state of the soul after this life, as the Christian, according to the gospel.

Of the many works which have treated of this important subject, we may mention one by an eminent German naturalist, J. H. F. von Autenrieth, *Über den Menschen und seine Hoffnung einer Fortdauer vom Standpunkte des Naturforschers* (On Man and his Hope of Immortality, as deduced from the Light of Nature) (Tübingen, 1815).

The Pentateuch, as many theologians believe, contains nothing relative to a future life. The rewards and punishments which Moses proposed, are all temporal, and the latter, he threatens, will be extended even to the third and fourth generations, but not to a future state. The writings of the Old Testament seem to show that the Jews had no belief in the immortality of the soul, until after they had become acquainted with the doctrines of the East in the Babylonish captivity, previous to which they seem either not to have believed in it at all, or to have held the return of the soul to the Supreme Spirit, as Solomon, for instance, teaches. The Pythagoreans and Stoics held this doctrine, as likewise several fathers of the church. In Maccabees, written long after the Babylonish captivity, the belief in the immortality of the soul, and a state of retribution, is expressed in positive terms. The transmigration of the soul, believed by the Pythagoreans, was not adopted by the Stoics. Epictetus says, "You do not go to a place of pain: you return to the source from which you came—to a delightful reunion with your primitive elements: there is no Acheron, no Tartarus, no Cocytus, no Phlegethon." Seneca, Epicurus, and Democritus, also teach the same. The Peripatetics adopted the same doctrine, but their founder considered death in a less consoling light. "Death," says Aristotle, "is the most terrible of all things: it is the end of our existence, and after it, man has neither to expect good nor to fear evil." In 1794, the French people passed a decree, acknowledging the immortality of the soul, and the existence of a Supreme Being.

IMPALEMENT (from *patius*, Latin, a stake); the putting to death by thrusting a stake through the body, the victim being left to perish by lingering torments, which sometimes last for days, and are aggravated by a feverish thirst. This manner of inflicting death was known to the Romans, though not practised by them. It is used by the Turks, as a punishment for Christians who say any thing against the law of the prophet, who intrigue with a Mohammedan woman, or who enter a mosque. Suleyman, a young Mussulman, the assassin of general Kleber, in Egypt, was impaled in the presence of the French army. He died, after several days of the most horrible torments, and not until after the birds of prey

had already torn the flesh from his body. The horrors of this scene exceeded even the fearful description of impalement in the Corsair.

IMPANEL. See *Jury*.

IMPEACHMENT. An impeachment is an accusation and prosecution for a crime or misdemeanor; but is distinguished from other criminal prosecutions, either by the tribunal before which the proceedings take place, the rank or office of the party accused, or the offence alleged, or by all these circumstances; for the constitutions and usages vary in different states in regard to the offences which are the subjects of an impeachment, as well as in regard to the descriptions of persons who are subject to this kind of prosecution, and the constitution of the tribunal having this jurisdiction. The term *impeachment* is usually applied to prosecutions of judicial and executive officers for misdemeanors involving an abuse of their official functions, or immediately connected with those functions. The necessity of some tribunal, distinct from the ordinary courts, for the trial of certain offences, or for any high misdemeanor in certain officers, is apparent, since the judges of the highest courts cannot, in all cases, safely be intrusted with the trial of each other; and if they could be so trusted, the duty of persons, who are, in the ordinary course of administration, associated together in the exercise of their public functions, to try their fellows for offences involving not only reputation, but life, would be most ungrateful, and too painful to impose, even if it could be supposed that justice would always be strictly administered; and, besides, the ordinary judicial tribunals are not so constituted, in all states, as effectually to secure them against the influence and power of the officers of the state. The first object, then, in trials of this description, is to bring them before a tribunal sufficient in authority to overawe any individual, however high or powerful. In countries governed by absolute monarchs, or those whose prerogatives overbear all other powers in the state, the practice is, either for the sovereign himself to give decisions in those cases which are usually the subjects of impeachment, or to constitute tribunals for this purpose by special commission, which is, in effect, equivalent to the direct exercise of those judicial functions by the sovereign himself; for if he has any strong bias in the particular case, he will be influenced by it in the appointment of the judges, as much as he would be in the decision, were he to act as judge himself. But in every free government, that is, in every government under which each citizen knows no absolute sovereign but the law itself, and every one, whether ruler or ruled, is constrained to an unqualified submission to its sovereignty, there must be a permanent tribunal established by the fundamental constitution, for the application of the sovereign law to try the judicial and executive officers, in respect to acts done by them in their respective branches of the administration of the government. This is one of the indispensable parts of a well constituted government, since it guarantees the sovereignty, and the faithful administration of the laws. It is therefore a part of the government in which the whole people are as directly interested as in the establishment of the ordinary tribunals.

The charter of the French government, granted at the restoration of the Bourbons, follows the British constitution in lodging this judicial power in the house of peers. The powers and jurisdiction of the British house of peers are very extensive in respect to impeachments, and, at the same time, not very precisely defined. It does not appear distinctly what persons or what misdemeanors are exempted from this jurisdiction; but it is, in practice, usually exercised in respect to misdemeanors of an important

character, alleged against judicial or executive officers. These prosecutions are instituted by the house of commons, and are usually commenced by sending an oral message from the house of commons to the lords, announcing the intended impeachment; and afterwards articles of impeachment are drawn up much in the form of an indictment, and the house of commons attends the prosecution as a committee of the whole, or appoints managers to conduct the prosecution, and demand judgment. As the crimes triable by impeachment are not limited, so the severest punishments may be inflicted in pursuance of the judgments rendered.

In the United States of America the constitutional provisions, on the subject of impeachment, are derived from the British constitution, but not without important modifications. By the constitution of the United States, the senate is the high court for the trial of impeachments, which are instituted by the house of representatives, as in England by the commons, and all executive and judicial officers are amenable in this mode of trial. In case of the impeachment of the president of the United States, the chief justice of the supreme court of the United States presides, but in no other case. The constitution of the United States does not require any particular number of the senators to be present, in order to constitute a court of impeachment. The members of the senate and house of representatives are not liable to impeachment, each house having jurisdiction over its own members. Managers are appointed, on the part of the house of representatives, to conduct the prosecution. The party impeached is heard by counsel, if he choose. The arguments having been heard, the senate deliberates with closed doors, but the judgment is given publicly. No person is convicted without the concurrence of two-thirds of the members present. The judgment extends only to removal from office, and disqualification to hold any office of honour, trust, or emolument, under the government. In the several states, most of the constitutions contain provisions similar to those of the constitution of the United States, the senate, or upper house, being the court of impeachment, and the house of representatives, or lower house, being the prosecutors.

**IMPERATIVE.** In grammar, the imperative mood of a verb is that which expresses command, entreaty, advice, exhortation; as, *go, attend, &c.*

**IMPERATOR** was the name given by the Romans to the commander-in-chief of an army, and *imperium* signified *military command*. *Imperator* was a title of different import in different times. The consuls originally bore the title of *imperator*, before they were called *consuls*. The name was afterwards given by the soldiers and senate to a general, after a great victory, and he retained it till after his triumph. In later times, no one received this title who had not defeated a hostile force of at least 10,000 men. After the overthrow of the republic, *imperator* became the highest title of the supreme ruler. The successors of Augustus used it, and expressed the same thing as the hated title of *king*. In still later times, it had the signification which we attach to the word *emperor*. It was still given, however, to triumphant generals, and, in this case, had its old signification. The emperors appear to have used it, because they were considered as superior to all the generals. In the times of the republic, this title was placed after the name; for instance, *Cicero imperator*: as the title of an emperor, it stood before the name. *Imperator* was a surname given by the inhabitants of Preneste to Jupiter, whose statue was carried to Rome, and placed in the capitol, by Titus Quinctius, when he captured Preneste. See *Emperor*.

**IMPERIAL CHAMBER.** See *Chamber Imperial*.

**IMPERIALI-LERCARI**, FRANCIS MARIA; doge of Genoa. Louis XIV. bombarded Genoa during his dogeship, in revenge for her adherence to Spain for fifty years. The doge was obliged to ask the pardon of Louis in person, and attended by four senators. Imperiali conducted himself with great dignity in this humiliating affair, and when asked what he found most remarkable at Versailles, gave that celebrated answer, "To see myself here."

**IMPRESSION**, in the arts, is used to signify the transfer of certain figures by pressure from a hard to a soft substance. This transfer affords the means of multiplying copies, and takes place in typography, copper-plate printing, lithography, &c. Engravers in copper and wood work in plane surfaces; the gem and stamp engravers, however, produce elevated or sunk figures; consequently, the impressions appear in relief, and the substances which receive them must be susceptible of being raised or depressed. In order to obtain impressions from copper-plates, a colouring substance must be put in the incisions of the plate. In the case of wood-cuts, the colouring matter is applied to the elevations. In both cases, the copy is procured by pressure. There are two kinds of impressions:—

1. That executed upon plane surfaces, as in lithography, copper-plate printing, and copies from woodcuts. The instruments for it are the printing, rolling, and lithographic press. (See article *Copper-Plate Printing*.) The goodness of the copies depend partly on the care and skill of the printer; partly also on the degree in which the plate has been used. The best copies are always among the first hundred, and are called, with us, the *proof impressions*; on the continent, *avant la lettre*, i. e., those struck off before the name of the engraving is inscribed on the plate. These are sold at a higher price than the subsequent impressions. An engraved plate affords more good copies than an etched one, and this more than one in aqua tinta. Copies are taken from woodcuts in the same way as from copper-plates. The same degree of care, however, is not necessary in conducting the process.

2. Copies in relief. These are impressions of medals and gems, or stamps, so as to leave raised or sunken figures (*empreinte*). Medals and engraved gems are valuable, as historical monuments and works of art, and the mode in which copies of them are made is a matter of importance. Representations of them in copper-plate engravings, cannot properly express their character as works of art. Impressions are therefore taken immediately from them, by means of fine sealing-wax, sulphur, wax, glass, &c. Copies in vitreous substances are called *pastes*. See *Casting*, and *Pastes*.

**IMPRESSMENT OF SEAMEN.** See *Seamen*.

**IMPRIMATUR** (*Latin*, let it be printed); the word by which the licenser allows a book to be printed, in countries where the censorship of books is exercised in its rigour. An account of this worst species of tyranny has already been given under the head of *Books, Censorship of*, (see also *Index*). Milton, in his eloquent speech for unlicensed printing or *Areopagitica*, humorously describes this practice of licensing books, exhibiting a specimen of what he calls a quadruple exorcism, approved and licensed under the hands of two or three monks—"Let the chancellor Cini see if this work may be printed;" (signed) V. R., vicar of Florence. Then comes the chancellor—"I have seen this work, and find nothing against the Catholic faith and good morals;" (signed) N. C., chancellor of Florence. Then the vicar reappears—"Considering, &c., this work may be

printed;" (signed) V. R.; and, finally, *Imprimatur*, signed by the chancellor of the holy office, in Florence.

**IMPRISONMENT FOR DEBT.** See *Debtor and Creditor*; also *Capias*.

**IMPROMPTU** (from the Latin phrase *in promptu habere*, to have in readiness); properly, something which is done or said without preparation, on the spur of the moment. It is used particularly to signify extemporaneous poetical effusions.

**IMPROPRIATIONS**, in the English church; benefices in the possession of laymen, those annexed to ecclesiastical corporations being called *appropriations*, though they are sometimes identified. Blackstone gives the following account of them. Benefices are sometimes appropriated, that is, perpetually annexed to some spiritual corporation, either sole or aggregate, which the law esteems as capable of providing for the service of the church as any single clergyman. This contrivance sprang from the policy of the monastic orders, who begged or bought all the advowsons within their reach, and then appropriated the benefices for the use of their own corporation. Such appropriations could not be completed without the king's license, and the consent of the bishop. When it was once made, the appropriators and their successors became the perpetual parsons of the church. Blackstone is of opinion that appropriations may still be made in this way. Those formerly made, were originally annexed to bishoprics, prebends, religious houses, manoreries, and certain military orders; but on the dissolution of the monasteries in the reign of Henry VIII., the appropriations of the several parsonages belonging to them were given to the king, and were afterwards granted out, from time to time, by the crown. The appropriator deputed some person to perform divine service in such parish, who, being merely his deputy or vicegerent, was called *vicar*, whose stipend was at the discretion of the appropriator. The distinction, therefore, of a parson and vicar, is that the former is entitled to all the ecclesiastical dues of his parish, while the vicar is, in effect, only the curate of the real parson (the appropriator), and receives but a part of the profits. It is computed that there are 3845 improprations in England.

**IMPROVVISATORI**; the name given, in Italy, to poets who compose and declaim, extemporaneously, a poem on any given subject, or sing it, accompanying their voice with an instrument. Among barbarous nations, where fancy is strong, lively, and unrestrained, the gift of extemporaneous poetry, especially when assisted by music, is not uncommon (for instance, among several of the African and American tribes); and, from several passages in the ancients, we may infer that the oldest Greek poets extemporised. In modern Europe, this talent appears a natural production of the Italian soil. Spain too, and especially, Minorca and Valencia, appear not to be without traces of a similar poetic character. After this art had been introduced into Italy, with the Provencal poetry, in the twelfth century, Petrarch appears to have practised it; at least, he is known to have introduced the custom of the *improvvisatori* accompanying their song with the lute. Since the revival of letters, there have been, in Italy, persons of both sexes who have composed, in this manner, poems of considerable length. The Latin language was at first used, which, until the end of the fifteenth century, was the language of the learned. The love of this poetry was quite a passion under Leo X., at the courts of Urbino, Ferrara, Mantua, Milan, and Naples. One of the oldest poets was Serafino d'Aquila (born in 1466, died in 1500), a poet now forgotten, but, in his own time, the rival of Petrarch. He was sur-

passed by his contemporary Bernardo Accolti, called *l'unico Aretino*. It is said that, when he repeated his verses in a public place, every thing was in motion, the shops were shut, occupation ceased, and learned and ignorant all rushed towards him. Of nearly equal fame was the Florentine *improvvisatore* Cristoforo, surnamed the Highest (*Altissimo*). Among the *improvvisatori*, towards the end of the fifteenth and at the beginning of the sixteenth century, were Nicolo Leonicensi, Giammario Filelso, Pamfilo Sassi, Ippolito di Ferrara, Battista Stromi, Piero, Nuccio Franciotti, Cesare da Fano. Three poets of this time were blind—Cristoforo Sordi, Aurelio Brandolini, and his brother Rafello.

The learned Greeks, who, at the beginning of the sixteenth century, fled from Constantinople to Italy, there spread their customs, together with a taste for their language and literature. In different cities of Italy, they introduced the *symposia*, in which were united the pleasures of the table and the pleasures of the mind. Leo X. was very fond of them, and willingly invited learned men to his table. Among them was his favourite Andrea Marone, a great *improvvisatore*. The contemporary authors relate wonderful things of his talent. Adrian VI., who looked upon poets as a sort of idolaters, banished him from the Vatican, where Leo had assigned him a lodging: but Clement VII. recalled him. Another poet, Querno by name, was a sort of court fool to Leo. Being very fond of wine, he obtained permission to drink from the pope's own glass at table, on condition that he would make at least two Latin verses on every subject proposed to him, and, if they were bad, his wine was mixed with at least an equal quantity of water. Leo called him, in jest, the arch poet.

After the death of Leo, learned men wrote in the *lingua volgare*, and the *improvvisatori* followed their example. We may suppose from this that their numbers increased. We will mention only a few of the most famous. The first is Silvio Antonmar, born at Rome in 1540, of an obscure family, and raised by his talents to the dignity of cardinal. He was well acquainted with the ancient languages, and skilled in all the sciences. On account of his power of improvisation, he was surnamed *Poetino*. On a fine evening in the spring, he once began to recite to a numerous circle, in a little grove in the country, when a nightingale, apparently attracted by his song, perched upon a neighbouring tree, and, emulating him, as it were, began to sing with extraordinary vivacity. The astonishment of the hearers at this unexpected contest, gave a new impulse to the spirit of the poet, and, excited by these circumstances, he left his former subject, addressed the nightingale, and praised the melody of her voice and the beauty of her song, in verses so full of harmony and feeling, as to draw tears from those around him.

One of the most celebrated of the *improvvisatori*, was Perfetti, born in 1680, at Siena, died 1747, at Rome. We have from Fabroni a biography of this poet: two volumes of his extemporaneous poetry appeared in 1748. He could throw a peculiar charm over every subject, and possessed such a wonderful memory, that in his last verses he recapitulated all that he had said before. He had the appearance of an inspired man, and when he had finished, he was generally exhausted and overcome with fatigue. He recited his verses singing, that he might gain time to think, and might better follow the metre, and was very willing to be accompanied by the guitar. His favourite metre was the orosyllabic. The most glorious day of his life was that upon which (during the papacy of Benedict XIII.),

he received, through the interest of the princess Violante of Bavaria, the crown of laurel at the capital—an honour which was then the more flattering, because it had not yet lost its value by being frequently given, since Petrarch and Tasso had alone been judged worthy of it. The rights of a Roman citizen, and the privilege of adding a laurel crown to his arms, were new honours given to him.

Metastasio, also, at a very early period, showed an extraordinary talent for this kind of poetry; but the exercise of it cost him much effort. After having declaimed for some time, he felt all his strength exhausted; it was necessary to carry him to bed, and to revive him by medical means; but his strength did not return for twenty-four hours. He was obliged, therefore, from regard to his health, to give up so dangerous an art.

Females, also, have been highly distinguished for this power. Quadrio mentions three celebrated *improvvisatrici*—Cecilia Micheli of Venice, Giovanna de' Santi, and a nun, Barbara of Correggio. No one of these obtained greater fame than Maddalena Morelli Fernandez, under Pius VI., among the Arcadians, called *Corilla Olimpica*, who lived in Tuscany, and excited the admiration of all travellers. She was born at Pistoia, where her talents, carefully formed by diligent study, were early developed. The applause which she obtained in Italy, induced the emperor Francis I. to invite her to Vienna, where she was received with distinction, and loaded with favours. The empress Catharine invited her to Petersburg, but the fear of a cold climate prevented her from going thither. The academy of the Arcadians chose her a member, and, in 1776, she was publicly crowned in Rome, and received from the Roman senate the title of *nobile cittadina*. She left Rome, and afterwards lived at Florence, where she died in 1800. Several females gifted with similar talents, have appeared in later times—Bandettini (q. v.), Fantastici at Florence, Mazzei, by birth Lanti; the last of whom, perhaps, surpassed all the others by the fertility of her imagination, by the richness and the purity of her language, and by the harmony and regularity of her verse. She also attempted tragedies. In 1764, there died at Verona the celebrated *improvvisatore* Zucco, who left behind him a worthy scholar and successor, in the abbé Lorenzi. The advocate Bernardi also attained to some celebrity in Rome.

Among the *improvvisatori* of our times, Francisco Giannini, of whose extemporaneous poems a collection appeared in 1795, has obtained great reputation; and also Settimi. Tomasso Sgricci of Arezzo is still more famous, who, in 1816, produced, in Florence, an extemporaneous tragedy, of which the subject and the characters were given by the spectators. In Paris, he likewise produced, with great applause, the tragedy of Missolonghi, in 1826. In Turin, he declaimed, extempore, the tragedy of Hector, which the stenographer Delpino printed (Turin, 1823), and in Florence, a tragedy on the death of Mary Stuart. (See *Rome in the 19th Century*.) He received, in reward, letters of nobility.

The printed works of the *improvvisatori* who have been most admired, have never passed mediocrity. Perfecti was therefore wise enough not to allow any thing of his to be printed, and it is probable we should not have had such beautiful poems from Metastasio, if he had not been obliged to renounce extemporaneous poetry. The cause is very evident, without its being necessary, however, for us to suspect the taste and penetration of its admirers. The real or apparent inspiration of the poet, his lively feeling, his striking action, the sound of his instrument, and, in general, the whole effect of a living

actor, cannot fail to produce powerful effects, and leave no time for criticism, even if the poetry is of an ordinary character. Bouterwek justly says, in his *Geschichte der Ital. Poesie* (History of Italian Poetry), "Among the poetical curiosities of modern Italy, the art of the *improvvisatori* has higher claims on our attention, than most printed collections of modern Italian poetry. Their art shows with what flexibility and power an Italian fancy, when once excited, can string together words and images in verse. It thus becomes manifest, how an Italian, even with a moderate cultivation of mind, is able to increase, by a little volume of pretty good verses, the number of those which he already finds, when he has once by heart the poetry of his predecessors. The artificial and yet happy enthusiasm of modern *improvvisatori*, is a living monument of the former achievements of Italian intellect." It is surprising that almost all the *improvvisatori* are born in Tuscany or Venice, principally at Sienna or at Verona, and that their art has been transmitted in uninterrupted succession.

The German Karschin, daughter of a peasant, whose cows she tended, would have been much admired as an *improvvisatrice* in Italy. The first poet who made public exhibitions of this kind, among the Germans, was the talented Wolf of Altona, in 1824 (now professor of modern languages at the gymnasium of Weimar), who appeared with applause in several places. In France, in 1825, Eugene de Pradel gave several successful evening exhibitions of the same talent.

INA; king of the West Saxons, in the seventh and eighth centuries. He succeeded Ceadwalla, about 689, and, after having obtained advantages over the people of Kent, in 694, he turned his arms against the Britons, from whom he wrested Somersetshire, and other parts of the west of England. He then made war on the Mercians; but the contest was terminated, without much advantage to either party, by a bloody battle, which was fought in 715. The latter part of the reign of Ina was spent in works of peace, and he closed his days in a monastery, having resigned his crown in 728. He is celebrated as the principal legislator of the Anglo-Saxons. His laws, some of which are yet extant, served as the foundation of the code formed by Alfred the Great. See Turner's *History of the Anglo-Saxons*.

INACHUS; a son of Oceanus and Tethys, the founder of the first royal race of Argolis, which ruled 392 years (from B. C. 1800). When Juno and Neptune contended for the dominion of Argos, Inachus, who was the arbiter of the dispute, adjudged it to Juno. He is particularly famous on account of his daughter Io.

INCA, or YNCA; an appellation which the natives of Peru give to their kings and princes of the blood. The Chronicle of Peru thus relates the origin of the incas:—This country had been a long time the theatre of all sorts of wars, horrible crimes, and dissensions, till at length there appeared two brothers, the one of whom was called Manco Capac. Of this person the Indians say he built the city of Cusco, settled laws and policy, and taught them to adore the sun, and he and his descendants took the name of *inca*, which, in the language of Peru, signifies *king*, or *great lord*. These incas grew so powerful, that they made themselves masters of the whole country from Chile to Quito, establishing in every province their peculiar policy and religious institutions, and held it till the dispute between the brothers Huascar and Atahualpa, of which the Spaniards, under Pizarro, availing themselves, obtained possession of Peru, and put an end to the empire of the incas, in 1533. They number only twelve of these incas. It is said that the most cou-

siderable among the nobles of the country still bear the name of *inca*.

**INCARNATION** (from the Latin, the *becoming flesh*); a word used to express the descent of the Deity, or his manifestation in the flesh, under the human form; thus we speak of the *incarnation* of Christ. The Hindoos believe in innumerable incarnations of their deities. The most celebrated are the nine incarnations of Vishnu. See *Avatar*.

**INCEST**; a crime made such by positive laws, in compliance with the directions of religion. The law of nature does not recognise it: on this account, the Code Napoleon does not number it among the carnal crimes, on the ground that the punishment of such crimes leads only to their concealment, and that the punishment of public opinion is sufficient. Nature has, at all times and among all nations, forbidden matrimony and sexual intercourse between descendants and ascendants, not between brothers and sisters, who were allowed to marry among the Persians, Athenians, Egyptians, &c. The cultivation of the moral sentiment extended the forbidden degrees of relationship, and moral and religious pedantry carried the prohibition even to spiritual relationship. Dispensations were, however, granted for money. It is desirable that the crime of incest should be limited to the commerce of parents and children, brothers and sisters.

**INCHBALD, ELIZABETH**; a novelist and dramatic writer of great talent, was the daughter of a farmer named Simpson, and born at Stanningfield, in Suffolk, in the year 1756. Having lost her father at the age of sixteen, she went to London with the view of obtaining an engagement for the stage, where she married Mr Inchbald, then an actor of some celebrity, and accompanied him on several provincial tours, partaking in his engagements. He dying in 1779, she returned to London, and made her debut at Covent-garden, Oct. 3, 1780. She continued on the boards about eight years, and, from her great personal attractions, which she retained to a late period of her life, as well as from her natural talents, was a popular performer. After her retirement from the stage, in 1789, she depended principally on her literary labours for support, publishing several dramatic pieces, most of which had a temporary success, while some are even yet considered as what is technically termed *stock plays*, among the latter of which may be mentioned, *Such Things are*, a play; *Every one has his fault*, a comedy; and *Lover's Vows*. She also wrote two novels, which still hold a high place among works of fiction, and both of which display much original thought and genuine pathos—the one entitled, *A Simple Story*, (1791, 4 vols. 12mo) the other, *Nature and Art*, (1796, 2 vols. 12mo). She besides edited a collection of dramas, entitled the *British Theatre*, with biographical and critical remarks (in 25 vols., 12mo), during the period from 1806 to 1809; a similar collection of the most popular farces (in 7 vols., 12mo); and the *Modern Theatre* (in 10 vols. 1809). Her death took place at Kensington, Aug. 1, 1821, in her 66th year. This ingenious and able woman passed a life attended with many difficulties and temptations with unsullied reputation. Her *Life and Correspondence* was recently published by Bowden, in 2 vols 8vo, and displays in a striking light the noble and self-denying character of her nature. For many of her latter years, she lived in comparatively mean lodgings and in the strictest abstinence, in order that she might uphold in comfort some families dependent on her bounty.

**INCLEDON, BENJAMIN CHARLES**; an English vocalist, born at St Keveran, in Cornwall, about 1764. When only eight years old, he was articled

to Jackson of Exeter, under whose tuition he remained as a chorister in Exeter cathedral until his fifteenth year. In 1779, he entered the navy as a common sailor. His vocal abilities having attracted the notice of his officers, he was advised to try his fortune on the stage. In October, 1790, he made his debut on the London boards, at Covent-garden theatre, with great success, in the character of Dermont, in O'Keefe's musical farce of the *Poor Soldier*, and rose at once into a degree of popularity, which attended him till the infirmities consequent upon advancing years, and an irregular mode of life, compelled him to retire from the active duties of his profession. Of the diminution of his powers, however, he never could be persuaded, but constantly attributed his declining popularity to the caprice of the public. His voice—a rich tenor—combined uncommon power, sweetness and ductility, both in the natural and *falsetto*, and his intonation was singularly correct, taking his imperfect education into consideration. His articulation was, however, far from equal to his other qualities, being coarse, not to say vulgar. The better sort of the old English ballad, of which Steven's Storm, and Gay's Black-eyed Susan are, perhaps, among the finest specimens, was decidedly his forte: in this style of singing, he had no equal. Pecuniary embarrassments, arising from an utter carelessness of money and general improvidence, embittered the latter part of his life, which was closed at Worcester, February, 1826.

**INCLINATION**, in mathematics, means the direction of a line, with regard to a certain point (according to the sense of the ancient mathematicians, Apollonius and Pappus particularly.) In astronomy, this word signifies the angle which the orbits of the planets and comets make with the ecliptic or orbit of the earth. This angle is the smaller, the less the planet or comet is distant from the ecliptic. According to the latest observations of Lalande and Bode, this angle of inclination is, in the different planets, as follows:—Mercury 7°, Venus 3° 23' 20", Mars 1° 51", Pallas about 30°, Ceres 10° 47', Jupiter 1° 19' 10", Saturn 2° 30' 20", Uranus 0° 43' 45". More exact determinations with regard to Ceres, Pallas, Juno, and Vesta may be expected at some future period. The comets make frequently very great angles with the ecliptic, for they traverse the heavens in all directions. The inclination of the moon's path is different, according as the sun affects it differently, but it is between 5° 1' and 5° 17'. For the inclination of the magnetic needle, see *Magnetic Needle*.

**INCLINED PLANE**. The inclined plane is one of the three mechanical powers, or simple machines, formed, as its name imports, by a plane surface, supposed to be perfectly hard and inflexible, and which is always inclined obliquely to the weight or resistance to be overcome. The wedge is a modification of this machine, being formed of two inclined planes placed base to base. The screw is another modification, being, in fact, merely an inclined plane wound round the cylinder. This machine enables us to raise a given weight along the inclined surface to a given elevation, with less expense of force than would be required to raise it perpendicularly to the same elevation. This perpendicular height is called the *elevation of the plane*, and the two lines enclosing the angle which it subtends, are called the *base*, and the *length* of the plane. See *Mechanics*.

**IN CENA DOMINI** (*Bulla in Cena Domini*); the most remarkable of all the papal bulls, as it most strikingly shows the arrogance of the popes, and their pretensions as absolute rulers of the church, and the authority which they claimed over temporal princes. It is founded upon older papal decrees.

which declared all heretics and favourers of heretics, without distinction, and those who imposed taxes upon the clergy, for the purpose of supplying the wants of the state, solemnly excommunicated. After the fourteenth century, it was extended and modified by several popes. Pope Pius V. ordered that it should be read aloud in all the churches on Maunday Thursday, because many Catholic princes tolerated Protestants in their countries, and required contributions from the clergy. Philip II. and the republic of Venice forbade the publication, for the exhausted state of their treasuries would not allow them to spare the clergy, and even the emperor Rodolph II. and the archbishop of Mentz would not acknowledge a bull so prejudicial to the rights of sovereigns. Its authority was never admitted in France; but, in Naples in particular, from 1568, it excited great disturbances; for it was promulgated by the bishops and monks, without the permission of the king, and, according to the ordinance of the pope, the right of government to impose new taxes was denied. Notwithstanding this opposition, the bull received its latest form from pope Urban VIII., in 1627. This pope, in behalf of God, and by virtue of the power committed to the apostles Peter and Paul and himself, excommunicated and anathematized all Hussites, Wickliffites, Lutherans, Zwinglians, Calvinists, Huguenots, Anabaptists, Trinitarians; all who had fallen off from the Christian faith, all heretics, as well as all those who trusted, received, favoured, or defended them; all who read heretical books, without permission from the papal see; all who possessed and printed them, or defended them in any way whatever, whether public or private, or on any pretence whatever; and, finally, all schismatics who obstinately avoided communion with the Romish church. All who appealed from the decision of the pope to a council were threatened with the anathema; and if a university, college, or chapter, with the interdict. Pirates who disturbed the papal sea ("our sea"), from Argentaro to Terracina, and all those who robbed wrecked vessels of the goods of Christians, incurred this anathema. Moreover, those princes were anathematized, who imposed new taxes, or increased those already laid, except in those cases in which they were allowed by law or by the special permission of the papal see; also all forgers of papal letters; all who provided Saracens, Turks, or heretics with horses, arms, money, implements of war, wood, hemp, cordage, or any thing which could be of service to them in making war on Christians and Catholics; all who should prevent the carrying of provisions to the papal court; all who robbed, injured, or murdered travellers to the papal court; all who abused cardinals, papal ambassadors or bishops; all who appealed from the commands of the pope or his ambassadors to temporal courts of justice, or avoided the judicial decision of the pope in spiritual concerns, or compelled the clergy to appear before temporal judges, or made laws against the freedom of the church, or interrupted the bishops in the exercise of their judicial power; all who seized upon the revenue which the pope derived from churches and convents, or imposed taxes upon the clergy, without the consent of the pope, even though the offender were an emperor or king; all officers who interfered with the criminal jurisdiction of the clergy; and, finally, all who should attack or conquer the papal territory, of which Sicily, Sardinia, and Corsica formed a part. None but the pope can remove this anathema, and he only in the hour of death, when the person excommunicated has satisfied the offended church. The bull was ordered to be publicly posted up at Rome, and once a year, or oftener, every bishop was to read it to the assembled people.

This was done at Rome, till the middle of the 18th century, every Maunday Thursday, in the principal churches.

INCOMMENSURABLE, in mathematics; a magnitude which cannot be measured by another, taken as unity. Of this kind are, for instance, all square roots which are not whole numbers, as the square root of 12 = 3.4641 . . . and so on indefinitely.

INCUBATION. Birds, fishes, insects, worms, and reptiles, as is well known, lay eggs, from which the young animals are produced by means of warmth. The four last named classes leave the fecundation of the eggs to the warmth of the sun; birds employ the warmth of their own bodies for this purpose. The process which they use is called *incubation*. All known birds, with the exception of the cuckoo, discharge this office themselves. The cuckoo deposits its eggs in the nest of the hedge-sparrow and other small birds. The ostrich, contrary to the common opinion, sits upon its eggs, the male in company with several females, day and night. Among many sorts of birds, as the common hen, ducks, geese, &c., the business of incubation is confined to the female; among others, especially those which live in pairs, as the dove, lark, sparrow, &c., the male takes part. The female usually leaves the eggs for some hours, about noon, to seek food and bathe herself. In other species of birds, the male remains near the female during the process, protects her from injury, brings her food, &c. This is the case with the canary bird, goldfinch, linnet, &c. The perseverance and devotion of the female during the period of incubation is admirable. She submits to the most inconvenient postures, to avoid injuring her eggs, and forgets her food and her companions. If she is compelled by hunger to quit her post, she covers her eggs with feathers, moss, wool, &c. Birds in general become comparatively tame during this period. Others defend their nests with the greatest courage. The domestic hen boldly encounters the largest dog. Only a few birds living in a state of freedom, allow their nests to be disturbed. Many desert them entirely, if a man has displaced the eggs during their absence; for instance, the canary bird. The gradual development of the young bird in the egg has been observed, particularly in the case of the eggs of the domestic hen. The covering of the young bird, when it first leaves the egg, is a sort of down; this is gradually superseded by feathers. The little creature remains for some hours or longer, in the nest, under its mother, till it has become accustomed to the external air. The old birds, particularly the female, now manifest the greatest care for their young, in protecting them and providing for their wants. They bring them suitable food, which, when necessary, the mother softens first in her crop. The dirt of the young is thrown out of the nest by the old birds as long as the young remain blind. Water and marsh birds, soon after birth, leave the nest, and follow their mother into the water. The old birds teach them where to find their food. The mother protects them, takes them in stormy weather under her wings, and exposes herself to much inconvenience to save them from suffering. The time of incubation generally varies with the size of the birds. The linnet requires but fourteen days, the common hen twenty-one, and the swan forty-two days. In warm climates, the time of incubation is said to be somewhat shorter. In Africa, the hen is said to sit but thirteen days. With us, too, in very cold weather, geese and hens are known to sit much longer than in warm. The warmth required for fecundating the eggs is about 140° Fahr.

The artificial hatching of eggs is practised in Egypt. In Naples, ovens for this purpose were constructed in the fourteenth century. But in Egypt,

this art has been carried to a high degree of perfection. The ovens intended for this purpose are made of brick, and sunk some depth in the earth. They consist of two stories, connected with each other, and divided into several apartments. In a corner of the building is an oven, which is heated daily three to four hours, for ten days in succession, with cow and camel's dung, the usual fuel of the country. The heat is regulated by the feeling of the superintendent. The temperature to be produced is compared with the warmth of baths. When the heat is too great, some passages are opened for the air. The floors of the divisions or apartments are covered with mats, and a layer of straw thereupon, on which the eggs are laid, so, however, as not to touch each other. They are turned twice by day, and as often by night. After eight or ten days, the eggs are examined with a lamp, to ascertain the progress of the process of fecundation. Those which appear to be unfruitful are thrown away; the others, on the fourteenth day, are put in the upper story. On the twentieth or twenty-first day, the young bird issues out. The owner of the oven receives a third part of the eggs for his trouble. The inhabitants of a village called Berme, in the Delta, are the persons who carry on this art throughout the country. In China, also, artificial hatching is practised. The eggs there are put in wooden boxes, which are filled with sand, and placed upon heated iron plates. Of late, a Frenchman has published a work on this subject, in which he seeks to introduce the Egyptian ovens on an improved plan. He heats his ovens with boiling water.

INCUBUS (Latin, *incubus*, one who lies upon); a spirit, to whom was ascribed the oppression known by the vulgar name of *nightmare*, in Greek *ephialtes* (from *ει* and *αλλωμαι*, I leap upon. The English *nightmare* is from *mair*, an old woman or hag, in which form the spirit was generally supposed to appear, pressing upon the breast, and impeding the action of breathing. The French *cauchemar* or *cochemar* (*qui couche sur*) is of the same character and origin. These demons play an important part in the superstitions of the middle ages, having been, perhaps, not unfrequently employed, like the elder gods of Greece, to cloak the advances of earthly lovers. The nuns and other young ladies of the middle ages were not always safe from their violence or their persuasions, as numberless tales and grave histories abundantly prove. Augustin (*De Civit. Dei*) mentions the fact that *Syleanos, Panes, et Faunos, quos vulgo Incubos vocant, improbos saepe extitisse mulieribus, et carum appellasse ac peregrisse concubitus*. The word is also used for the oppression or feeling of suffocation which sometimes comes on during sleep. The sufferer experiences a short period of intense anxiety, fear, horror, &c.; feels an enormous weight on his breast; is pursued by a phantom, monster, or wild beast, whom he cannot escape; is on the brink of a precipice, from which he cannot remove, or is, perhaps, rolling down it without being able to make any exertion for his safety, and his limbs refuse to do their office, until he suddenly awakens himself by starting from his recumbent posture, or by a loud cry; he is then in a state of great terror, and the body is often covered with sweat. It is generally owing to repletion and indigestion, and is often superinduced by lying on the back. It is most common in those seasons of the year which most increase the volume of the fluids—in spring and autumn. Homer (*Il.* xxii. 200) and Virgil (*Æn.* xii. 906) have given striking pictures of its benumbing power, and Fuseli has represented its agonies. He is said to have eaten an immoderate supper of raw pork, for the purpose of obtaining a vivid conception of his subject.

INCUNABULA (from the Latin, signifying *cradle*) is a term applied to those editions of books which were printed previously to the year 1500. Peignot explains it as signifying editions, *qui touchent au berceau de l'imprimerie*. The term is most properly confined to the period above-mentioned, because the art of printing was completely formed, in all its principal parts, in that period. Panzer's work comes down, indeed, to 1536, and Mattaire's still later; but this forms no objection to our limitation, because these two writers had regard to the history of printing in general, rather than to the history of the incunabula in particular. A knowledge of them is important, as they are the best, and often the only sources, from which a minute history of the early progress of the art of printing can be drawn; but notwithstanding the investigations of bibliographers, much remains to be done in determining the particular characteristics and mutual relations of these works. Many of these works, too, are important and interesting, on account of the illustration which they afford of the history of the art by their ornaments, and on account of the value of the first editions (*editiones principes*), of ancient and modern classics in a critical respect. We shall here treat of them in reference to their value to professed collectors.

1. The first beginnings and attempts at printing will naturally be objects of their search, among which are the xylographic specimens, and the earliest impressions bearing date, which begin with the indulgences of Nicholas V., 1454; although the oldest printed book, whose date is undoubted, is the Psalter of 1457.

2. Next to these are the first impressions of particular countries and places, which are generally not less rare than the preceding.

3. The first books printed in a particular language or with certain types. The oldest impressions are in the Gothic type, as it is called; the round or Roman character, which afterwards became the most common, particularly in Italy, came into use somewhat later. Single Greek works, cut in wood, were first used in 1465, in Cicero's *De Officiis*, and in the edition of Lactantius of the same year. The first book printed entirely in the Greek type, was Laskaris's Greek Grammar, which appeared at Milan, 1476.

4. Editions from those presses which did not do much, and, from the more fertile presses, those editions which are peculiarly rare; e. g., the Mestri editions of the old Roman classics.

5. Editions in which certain typographical improvements were first introduced; as J. Nider's *Præceptorium divinarum Legis* (Cologne, Koelhof, 1472, folio), the first book printed with signatures; *Sermos ad Populum predicabilis* (Cologne, *ther Harnen*, 1470, 4to), the first with the pages numbered; *Cicero De Officiis* (1465), the first in quarto; and the *Officium Beate Mariæ Virg.* (Venice, Jenson, 1473, 32mo), the first in the smallest form. Title pages first appeared after the year 1485.

6. Editions with the first, or with remarkable attempts to apply the arts to the ornamenting of books. The first printed book with copper-plates is Antonia da Siena's *Monte Santo di Dio* (Florence, 1477, fol.). The most remarkable wood-cuts, of which the Strasburg printer, Gruninger, was very fond, are to be found in German and Italian editions. In this division may also be included copies with excellent miniature engravings.

7. Single copies which are celebrated on account of some particular circumstances; e. g., those printed on parchment and with gold letters, of which we have some from the fifteenth century), &c. Of the impressions on parchment, on which whose

editions were at first printed, and the greater part of the copies, even of later editions, (e. g., of the Latin Bible of 1462), those are particularly sought after, which issued from presses that printed but little on parchment; e. g., Schweinhelm and Pannars at Rome, by whom only six parchment editions are known to have been published.

8. Finally, there are some particular collections or series, which collectors pride themselves particularly on possessing; e. g., the six Greek works (*Anthologia, Apollonius, Rhodius, Euripides, Callimachus, Gnomæ, Musæus*), printed in capitals by Alopa at Florence (1404—96), or the Greek works printed at Milan with a very round type, of which Laskaris (1476) is the first, and Suidas (1499) the last.

Editions from celebrated presses of the fifteenth century are also highly valued; e. g., those of Schweinhelm and Pannars, and the English printers Caxton, Pynson, and Wynkyn.

For information concerning the incunabula, see Panzer's *Annales Typographici*, together with his *Annals of German Literature*, which together contain the most complete catalogue, to the year 1536. Mazziere's *Annals* are far less complete, but they come lower down, and enter rather more into details. Serra Santander's *Dictionnaire Bibliographique choisi du 15 Siècle* (Brussels, 1805, 3 vols.), is a useful work on the most interesting incunabula. It contains much information on the incunabula of Spain and the Low Countries, which is wanting in Panzer. Besides these works, we may find accounts of particular incunabula, in the local histories of printing (especially in Audiffredi's works on Roman and Italian printing), in the accounts of some particular printers of the fifteenth century (Gutenberg, Jenson, Aldus, Giunta), and in the works which treat of the incunabula of some single libraries, as those of Fossi, Dählén, (*Bibliotheca Spenceriana*), &c.

INDEPENDENCE, in politics; the sovereignty of a people or country, as distinguished from a former dependence upon another country. When a successful attempt is made, by a portion of a people subject to a common government, to establish a separate government for itself, the struggle is generally closed by the acknowledgment of its independence on the part of the government from which it has seceded, though, in some cases, a complete separation is effected without any such acknowledgment, when the old government is too weak to undertake anything effective against the revolted provinces or colonies, and yet will not formally renounce its authority over them. In such a case, it cannot be supposed that such an acknowledgment is necessary to entitle the new state to be treated by other powers as independent. This was the case with the United Provinces and Spain, the latter not acknowledging the former for a long series of years. The South American republics, too, have not yet been acknowledged by Spain, but no one can doubt their independence. The just rule would seem to be, that a colony or province is independent whenever it declares itself so, and is able to maintain its independence, or is left in undisturbed enjoyment of it. In a complicated political system, like that of Europe, the acknowledgment of independence on the part of the old government, is diplomatically important; and without it, other European states are averse to enter into political relations with the new state.

INDEPENDENTS; a Protestant sect in England and Holland, which originated towards the end of the sixteenth century, during the reign of queen Elizabeth. The Independents declared the ceremonies of the Anglican church popish abuses, and heathenish. They agreed only in this point, differing among themselves on many points of doctrine. The

most zealous sect were the Brownists, whose founder, Robert Brown (q. v.), in 1580, attacked the discipline and ceremonial of the church of England, as unchristian. The name *Independents* is derived from the circumstance that each congregation formed an independent community, subject neither to bishops nor elders, nor any other ecclesiastical powers; the minister was elected and dismissed by the votes of the congregation, and every member had a right to preach. The principles of church government inculcated by the Independents, spread rapidly, and became a subject of alarm to the government; some were arrested, some executed, and many fled the country. The sect survived in England, under the name of *Congregationalists*; but the principles of Brown were modified. The name of *Brownists* they disclaimed, calling themselves *Congregationalists*, and consider John Robinson (q. v.) their founder. In the civil wars of England during the seventeenth century, the Independents formed a powerful party. See *Cromwell, Britain, and Puritans*. The English Independents now differ from other Protestant sects in rejecting any formula of faith, requiring only a profession of belief in the gospel; and their pastors are not ordained. Among them are several distinguished men.

INDEX. A scientific work becomes doubly valuable by a well arranged and complete index, made under the eyes of the author, which saves the reader an immense expense of time. A scientific work of value is a book of reference, and a book of reference without an index is like a chest with a troublesome lock, which tries our patience whenever we attempt to open it. The plan of some newspapers to issue a general index at the end of each year, deserves much commendation, and ought to be imitated by every editor who considers his journal worth preserving.

By the Roman Catholic church, *index* is used absolutely, to designate the catalogues, or list of books prohibited by ecclesiastical authority, on account of the heretical opinions supposed to be contained in them, or maintained by the authors or editors of them. The catalogue, or list of books absolutely prohibited, is simply called the *Index*, or *Index Librorum prohibitorum*; but when the list, or catalogue, is of books allowed to be read, after correction or alteration, agreeably to the orders of the papal authorities, it is termed *Index expurgatorius*, and, in the later indexes, the words *donec corrigantur* are subjoined to certain works, in order to render a separate expurgatory index unnecessary. (Townley's *Essays on various Subjects of Ecclesiastical History*, page 133.) The beginning of the prohibitory index is to be found in Gratian's Collection, being a prohibition to read pagan books by the council of Carthage, held about 400. The emperors also prohibited the reading of certain books. Constantine, for instance, prohibited the reading of the works of Arius. The popes, too, used to order obnoxious books to be burned. The books of whole sects are sometimes prohibited in a mass. The invention of printing in the middle of the 15th century, caused a rapid multiplication of books, and induced the papal hierarchy to prevent, if possible, the circulation of any which might prove injurious to the interest of the Romish church. Hence originated imprimaturs (q. v.), or official permission to print works; and the promulgation and diffusion of the doctrines of the reformation, in the following century, increased the determination of the powerful adherents of popery to suppress and to destroy all the books tinctured with Lutheranism, or maintaining any of the peculiar opinions held by the reformed churches. In 1546, in pursuance of an edict of the emperor Charles V.,

the university of Louvain published an index, or catalogue of books regarded as dangerous, of which a revised edition was published in 1550. Similar lists of interdicted books appeared, nearly at the same time, at Venice, Paris, Cologne, &c. (for an account of which, see Peignot's *Dictionnaire des Livres condamnés au feu, supprimés, ou censurés*, tom. i., pp. 256—266; and Mendham's *Account of the Indices, both Prohibitory and Expurgatory, of the Church of Rome*, pp. 17 et seq.) Philip II. of Spain having caused a catalogue of all books prohibited by the inquisition to be printed (Venice, 1558), pope Paul IV. followed the example, and ordered an *Index Librorum prohibitorum* to be published by the *Congregatio Sancti Officii* (see *Congregation*), in which not only all heretical books were noted down, but also all which tended to lower the Catholic hierarchy, many even written by Catholic clergymen. The first part contains the names of the authors whose works are altogether prohibited; the second, single prohibited works; the third, anonymous works. A particular part contains the names of forty-two booksellers, whose publications are altogether prohibited. After this, the councils published a number of such *indexes*, and these were followed by some for single countries; for instance, by the Sorbonne for France. The indexes assumed their most systematic form at the council of Trent, which, at its eighteenth session, referred the consideration of works to be prohibited to a select committee; and, in the twenty-fifth session, what had been done by that committee was referred to the pope (*Conc. Trid. Canones*, 177, 362, Paris, edit., 1824), that it might be completed and published with his authority. The work was accordingly published in 1564. Besides the catalogue of prohibited books, it contains general rules relative to such books, drawn up by certain persons deputed for that purpose by the council of Trent, and sanctioned by pope Pius IV. These rules, which are ten in number, are prefixed to the different indexes which have been published since that period. They are also contained in the Paris edition of the canons of the council of Trent, already cited (pp. 433—440), and a translation of them will be found in Townley's *Illustration of Biblical Literature* (vol. ii. pp. 478—485).

The Congregation of the Index, which forms a branch of the inquisition, holds its sitting at Rome, and has the right of examining generally all books which concern faith, morals, ecclesiastical discipline, or civil society, on which it passes judgment for suppressing them absolutely, or directing them to be corrected, or allowing them to be read with precaution, and by certain persons. Pius V. confirmed the establishment of this congregation. Persons specially deputed by it may give permission to Romanists throughout the world to read prohibited books, and the penalty denounced against those who read or keep any books suspected of heresy or false doctrine is the greater excommunication; and those who read or keep works interdicted on any other account, besides the mortal sin committed, are to be severely punished, at the will of the bishops. (Richard and Giraud, *Bibliothèque Sacrée*, tom. viii. p. 78.) The latest *Index Librorum prohibitorum* appeared at Rome, in 1819. For the preceding *Indexes* published in Spain, Portugal, and at Rome, between the years 1564 and 1806, see Mendham's *Account of the Indices*, &c., pp. 31—123.

INDIA; THE INDIES. This name has been very vaguely applied, at different periods, to different extents of country, and is still used in different applications. The name is derived by us from the Greeks, who seem to have borrowed it from the Persians, as it is unknown to the natives. It was

at first used by the Grecian writers to signify an indefinite extent of country lying beyond the Indus, with which they were acquainted only through vague and vague accounts obtained from the Persians. Darius crossed the Indus (B. C. 520), and conquered Cashmere and a part of the Penjab. Alexander, 200 years later, pushed his conquests a little farther, and the narratives given by his officers supplied Eratosthenes, Strabo, and Pliny with the materials which they arranged and abridged. Ptolemy, who flourished at a later period (A. D. 150), when commerce had made his countrymen acquainted with the southern parts of India, has given a more accurate account of it. He divides India into *India within* and *India beyond the Ganges*. The former was bounded on the west by the people of Paropamisus, Arachosia, and Gedrosia; on the north by the mount Imass, the Sogdians and Sacæ; on the east by the Ganges, and on the south by the Indian ocean. Other writers, as Arrian and Pliny, make the Indus its western limit. Strabo calls the southern and eastern boundary the Atlantic ocean. Of the two great rivers, the Indus and Ganges, the latter was not reached by Alexander, and was seen by very few of his followers. The Indus and its five great tributaries were known to all of them. A more accurate acquaintance with Upper India, obtained within the last thirty years, has proved the general correctness of the ancient accounts, and settled many doubtful points. Of the Deccan they knew nothing but the coasts, and of India beyond the Ganges they knew very little. The decline of the Roman empire, the rise of the Parthian empire, and particularly the extension of the Mohammedan power over Western Asia, broke off all direct intercourse between Europe and India. Religious hatred and commercial jealousy contributed to shut up the road to India against Europeans. Caravans were then the medium of Indian commerce, and through them the productions of the East were brought to the Mediterranean shores. Not until the Portuguese had doubled the cape of Good Hope (1498) were the Europeans able to visit that region of wealth. The islands of Java, Sumatra, Borneo, Celebes, the Philippines, the Moluccas, &c., were discovered, and have often been included under the general name of *India*, which comprised, on the continent, all that vast tract of country lying south of China, Thibet, and Persia. These regions have been divided by modern geographers into three parts—the islands, or the Indian Archipelago; India this side the Ganges, or Hindoostan; and India beyond the Ganges, or, as some writers call it, Chin-India, or Indo-China, including the Birman empire, Cambodia, Tonquin, Cochinchina, Laos, Siam, and the peninsula of Malacca. (See the separate articles.) The islands above-mentioned are Ceylon, the Laccadives, the Maldives, Andaman, the Nicobar isles, the Sunda isles, including Borneo, Sumatra, Celebes, Java, &c., the Moluccas, the Philippines. (See the articles.) When America was discovered, it is well known that Columbus supposed it to be the eastern coast of Asia, of which he was in search. These regions were, therefore, at first called *India*, and when the error was discovered, the name was retained, with the distinctive appellation of *West*, the proper India being called the *East Indies*. The Spanish kings assumed the title of *king of the Indies*, and the council for the colonies was styled the *supreme council of the Indies*. The name of West Indies was afterwards restricted to the islands, now so called, lying between North and South America.

*European Commercial Colonies in India.* In ancient times, India was the principal source of the commerce of the Phenicians, Carthaginians, and Egyptians. (See Heeren's *Ideas*, 1st vol., 3d part,

4th edition, 1824.) Until the end of the fifteenth century, the Europeans obtained the precious merchandise of India only second hand, partly through Egypt, where it came by the way of the Arabian sea, and partly from the long journeys of the caravans through the interior of Asia. This commerce was in the hands of the Venetians and Genoese, who furnished the European markets with the productions of Asia, and thereby became rich and powerful.

*Portuguese India.* The doubling the cape of Good Hope, which, in 1498, showed the way by sea to the riches of India, led the Portuguese to the possession of a kingdom in Asia. A few years after Vasco de Gama (q. v.) had landed on the coast of India, they were already the most favoured merchants upon the whole coast, and in spite of the active jealousy of the Mohammedans, who had hitherto monopolized the lucrative commerce of India, they formed settlements, and made commercial treaties with the Indian princes, in which the latter acknowledged the king of Portugal for their lord. Francis of Almeida, the first Portuguese viceroy in India (from 1505 to 1509), increased the fame of his nation in the Indian seas. Wherever he landed, he formed commercial establishments, and even took possession of Ceylon in 1506. His more famous successor, Alphonso of Albuquerque, who held the chief command between 1510 and 1515, confirmed the proud edifice of Portuguese power in the Indies. He built fortresses for the protection of the factories, and conquered Malacca, to which merchant ships from Japan, China, the Moluccas, the Philippines, Bengal, Persia, Arabia, and Africa, resorted; and the terror of his arms, which this conquest inspired, induced the most powerful princes of farther India to seek the alliance of the Portuguese. He afterwards acquired possession of the Moluccas, and with them of the rich spice commerce, and ended his triumphant career by the conquest of Ormuz, the richest and most powerful city on the Persian gulf, the possession of which he secured by a castle. Soon after his death, the Portuguese ruled from the Arabian to the Persian gulf; nearly all the ports and islands on the coasts of Persia and India soon fell into their power; they possessed the whole coast of Malabar to cape Comorin, and had settlements on the coast of Coromandel and the bay of Bengal; Ceylon was tributary to them; they had factories in China; and the ports of Japan, to which a tempest had shown them the way, were open to their merchant ships. Their power had attained this extent in 1542; and, for sixty years, they carried on their lucrative commerce without any considerable rivals. They determined the price of merchandise in all the European and Asiatic markets. No foreign vessel could take a cargo in the Indian ports, before the Portuguese ships were freighted; no ship was safe in the Indian seas without Portuguese passports; and even those which carried on commerce by their permission, could not trade in cinnamon, ginger, pepper, steel, iron, lead, and arms, because these articles were included in their monopolies. The central point of the Portuguese dominion, after the time of Albuquerque, was Goa, where the royal Portuguese governor, under the title of *viceroy* or *governor*, had his seat. By bold and often revolting acts of power, they secured their dominion in Asia. They bombarded the most powerful cities on the Indian coasts; they burnt the ships of their enemies in their own harbours; they instigated the inferior native princes to rebel against their sovereigns, that they might take advantage of internal dissensions to extend their own power; and they granted peace and their alliance to no prince who did not do homage to the king of Portugal, and confirm his submission by permission to build a castle in his capital. Even on the coasts

where they merely trafficked without governing, and where the natives were subject to the native princes, they ruled indirectly by the terror of their name. Portugal owed this power to a few able men, whose adventurous spirit led them to this distant scene of action. The inclination to knightly adventures, which, after the overthrow of the Moors, had no object of enterprise at home, found here a field for action. But the successors of the men who established the commercial greatness of their nation, were not endowed with the same talents. Avarice and love of plunder soon became the only motives of enterprise; the honour of the Portuguese name was sullied; a revolting abuse of power excited the resistance of the natives, who had been before armed against each other by the artful policy of the strangers, but now became united by the sight of their common danger. After the powerful John II., and the magnanimous Emanuel, weak princes succeeded to the throne of Portugal; under Sebastian, the disciple of the Jesuits, when the kingdom was fast approaching to its ruin, the Portuguese dominion in Asia was also lost. The union of Portugal with Spain, in 1580, decided the fall of their commercial power in India. The Spanish kings neglected the Asiatic settlements. Robbery, pillage, and insubordination prevailed there. Some commanders in India made themselves independent; others joined the Indian princes; and others became pirates. The Portuguese were treated as Spaniards by the Dutch and English.

*Dutch India.* The Dutch had previously gone to the great commercial market of Lisbon for Indian merchandise, but Philip II. closed the harbour of the Portuguese capital to the Dutch ships, on account of the revolt of the United Provinces, and thus obliged that industrious people to go to the sources of this commerce. They were engaged in fruitless attempts to find a passage to India by the Northern seas, where they might avoid their enemies, when Cornelius Houtmann (q. v.), a Dutchman who had made several voyages to India in Portuguese ships, offered his services to his countrymen. In 1595, he was sent, with four ships, to India, to explore the coasts, and gain information concerning the inhabitants and the commercial relations in that place, and he returned with favourable accounts; for, in this very first voyage, treaties of commerce were made with the princes of the island of Java. The company of merchants who had begun the undertaking, sent out admiral Van Steck, with orders to enter into treaties with the native princes, and to establish factories on the island, which was at a distance from the centre of the Portuguese commerce, but was near enough to the Spice islands to favour a contraband trade, and was very well situated for trade with China and Japan. The hatred of the natives against the Portuguese, who had at times landed here, assisted in the accomplishment of this enterprise. Several societies were now formed in Holland to prosecute the commerce with India; but the markets, both of India and of Europe, were soon overstocked. To avoid this inconvenience, and to be able to oppose a firmer resistance to the jealous Portuguese than they could do separately, the small commercial societies united in 1602, and formed the great East India company, which had power to make peace or war with the princes of Asia, to build forts, to maintain garrisons, and to choose a governor. Now, that they had formed settlements at Java and upon other points, and had made commercial treaties with several princes of Bengal, began the long struggle between the rivals. The Portuguese had the advantage of a better knowledge of the Indian sea, but the Dutch could rely on more powerful support from

Europe; for Philip II. and his successors often left their Asiatic settlements unprotected. Time and experience gave the advantage of knowledge to the Dutch, and their stronger and better served navy enabled them to take one place after another from the Portuguese. In 1621, the latter were stripped, by their victorious rivals, of the Moluccas; in 1633, of Japan; in 1641, of Malacca; in 1658, of Ceylon; in 1660, of Celebes, where the Portuguese had settled after the loss of the Moluccas, to retain by smuggling some part of the spice trade; and, after 1663, the most important places on the coast of Malabar, where they had longest maintained themselves, fell into the power of the Dutch. At the same time that the Portuguese were contending with the Dutch, the English also entered the lists.

*English India.* In 1600, queen Elizabeth gave to the merchants of London an exclusive right to the commerce of India for fifteen years; and, soon after, the four first merchant ships of the East India company sailed from Lancaster to the Moluccas. The profits upon this first voyage induced the associated merchants to use every exertion to overcome the obstacles which the new settlements of the Dutch, and those of the Portuguese, upon the Indian coast, placed in their way; and they soon succeeded in forming establishments and building forts in Java, Amboyna, and Banda, and shared the spice trade with the Dutch. This privilege, indeed, was soon after lost, the Dutch having obtained sole possession of the Moluccas; but the English were more successful in their settlements on the coasts of Malabar and Coromandel, and always repelled the attacks of the Portuguese. They obtained yet more important advantages in 1623, when the Persians requested their assistance to drive the Portuguese from Ormuz; for, independently of their share of the rich booty of merchandise which they gained, they formed a settlement at the entrance of the Persian gulf (Gambroon) and obtained possession of the commerce in silks, carpets, gold stuffs, and other Persian commodities. Thus, in the middle of the seventeenth century, the commercial power of the Dutch and British rose upon the ruins of the Portuguese. But the friendly reception which the natives had given to the Dutch, when they freed them from the hated power of the Portuguese, was soon followed by discontents. They saw that they had exchanged a hard yoke for one still harder; that avarice and a commercial spirit produced, under their new masters, the same effects, which, ever since the first arrival of the Europeans, had disturbed their peace and destroyed their freedom. The Dutch, as well as the Portuguese, were almost continually at war with the natives on the islands and on the continent, wherever they formed settlements. After the expulsion of the Portuguese from the Spice islands, the Dutch government became so oppressive as to compel the destruction of the spice trees upon all the islands except Amboyna. At Banda, the natives were massacred, because they would not submit to become slaves, and the whole island was divided among the whites, who used slaves from the neighbouring islands to cultivate their lands. The magnificent city of Batavia, upon the northern coast of Java, became, after 1619, the seat of the Dutch government in India, and the principal seat of the Asiatic trade of the East India company. From this place the governor-general, during the five years of his power, ruled with regal sway over the princes of the interior. Until modern times, when the whole European colonial system was shaken, and almost all the commercial establishments in Asia fell into the hands of the British, who ruled the sea, the Dutch, notwithstanding the struggles of the natives, remained in possession of their

settlements, among the most important of which were Surat, on the coast of Hindoostan; the government of Malabar, with Cochin, its fortress; that of Coromandel, with the fortified Negapatam; Chinsura, in Bengal; the government of Malacca, the farthest Dutch settlement at the southern point of the peninsula beyond the Ganges; Celebes, the only place where they formally ruled after disarming and subduing the native princes; Java, the Moluccas; and the southern coast of Borneo, their last settlement.

*Danish India.* Before we return to the English colonies in India, we must cast a glance at the other commercial establishments, those of the Danes and the French, likewise formed in the seventeenth century. A Dutch factor, Boschower, who had obtained from the king of Ceylon, as a mark of high favour, the title of prince, being coldly received when he returned home, from resentment offered his services to king Christian IV. for forming a colony in Ceylon. An East India company was immediately established in Copenhagen, and, in 1618, Boschower sailed for India with six ships, of which half belonged to the king, and the others to the company. He died on the way. The Danish mariner who commanded the ships was ill received at Ceylon, and immediately turned to the coasts of Coromandel, the nearest part of the Indian main. The native prince of Tanjore, granted him, for a yearly rent, a fertile strip of land, where were laid the foundations of the city of Tranquebar, and where, soon after, the fortress of Dansburg was built for the protection of the new settlements. The other Europeans, who had established themselves in India, at first placed no obstacles in the way of the Danes, who thus were enabled to carry on an extensive trade. But when the Dutch became more powerful and more arrogant, they excluded their new rivals from all the markets. The affairs of the Danish company declined; it ceded its possessions to the government, and, in 1634, was dissolved. After 1643, the Danes ceased to navigate the Indian seas. In 1670, Christian V. formed a new society, which he so generously supplied with ships, that nearly half of their capital came from his hand. This company had the right of making peace and war. It was soon involved in new quarrels with the Dutch and the princes of Tanjore, whom the latter had excited against it. It continued its feeble existence until 1729, when it was given up, as it could no longer maintain its small possessions. Two years after, it was again restored by Christian VI. It received a charter for forty years, with the right of carrying on an exclusive trade from the cape of Good Hope to China. It was so successful that, after the charter had expired, it was renewed for twenty years, but with a proviso taking the exclusive right to trade from the company, and allowing access to India to every Danish subject, on condition of the payment of a tax to the company. In the mean while, several settlements were made on the coasts of Malabar and Coromandel, in Bengal, in Behar, in Orissa, on the straits of Malacca, and they became so important to the navy and the commerce of Denmark, that the king, in 1770, bought them from the company, and took their officers into his service. The commerce to India and to China has, since then, been free to all Danish subjects.

*French India.* The East India companies of England and Holland were already rich, when the French had made only a few unsuccessful attempts, and had no immediate commerce with India. But the French minister of commerce, Colbert, was so loudly called upon to favour the enterprise of the nation, that he resolved, in 1665, to form a company, and to give to it, for sixty years, all the rights and

privileges which those of Holland and of England enjoyed. The company was to have a capital of 15,000,000 of livres. The island of Madagascar, at the entrance of the Indian sea and near the African coast, favourably situated for Trade with Africa, Persia, Arabia, and India, was chosen for the central point of their new establishments. But, in five years, the company was so reduced by bad management, and by the faithlessness of agents, that it ceded its possessions to the government. Things went on no better, and, in two years, all the French who had remained at Madagascar were massacred. In the mean while, instead of Surat in Guzerat, where the French had first deposited their goods, they chose the then unimportant village of Pondicherry, which soon after became a considerable city. During the seventeenth century, the commerce of the French did not flourish in India. The defects of the system of administration, military disasters, and the encroachments of the government, prevented the extension of the colonies, and some but just begun were immediately abandoned. The company finally gave up its privileges (which had been renewed in 1714), to the merchants of St. Malo. Under the administration of cardinal Fleury, order and activity were first introduced into these commercial enterprises, when the brothers Orri and Fulvy took the direction of them. Pondicherry soon recovered from its decline, and the Isle de France, which the French had possessed since 1720, admirably situated as a station for Indian commerce, soon became flourishing (1735) under the wise government of Bourdonnaye. The colony of Chandernagore, on the Ganges, prospered under the management of Dupleix. French ships navigated all the Eastern seas, where a lucrative commerce could be expected. In the naval war between the English and French (1745—47), the latter maintained their possessions in India with great valour, although they received but little support from Europe; but, after the peace of 1748, their power rose to its height by their influence on the wars of the Indian princes. They obtained large possessions on the coasts of Golconda, Orissa, and Coromandel, which were, however, too much separated to give each other mutual support. During the war with England (1753—63), the French gradually lost every thing in India. The peace restored to them only Pondicherry and Mahé, and gave them three small factories in Bengal, with weak garrisons. Since this time, they have lost and regained Pondicherry several times, and hold it by the peace of Paris, of May 30, 1814. The British are now the ruling commercial nation in India. Upon the foundation laid there, as we have related, in the seventeenth century, has arisen the proud edifice of their power; and, since 1702, the funds of all the smaller companies which before had been formed, were united with those of the East India company. See *East India Companies*.

*Indian Languages.* If the religious systems of the natives of India, and the high antiquity of their traditions, were not a sufficient proof that India is truly *Medgamma*, *Medhya-Deha* (the central land), and its inhabitants a primitive people, a survey of the languages of the country would render it evident. Although the missionary Henry Roth, in 1844, and the Jesuit Hanzelben, in 1699, engaged in this study, it is only since 1790 that it has been more thoroughly investigated by Paulino, Sir W. Jones, Wilkins, Forster, Carey, Marshman, Wilson, Colebrooke, Ward, Marsden, Bopp, and others. According to an Indian treatise on rhetoric, given by Colebrooke, there are four leading languages: Sanscrit, Pracrit, Paisachi or Apadhransa and Marathi or Misra. As those double appellations are founded on different passages of that treatise, Cole-

brooke considers the Apadhransa the same as the Magadhi, and the Paisachi and Misra as one; so that, in reality, the Sanscrit, the Pracrit, and the Magadhi are the only leading languages. But, as even English critics have remarked, the passage quoted does not seem to have justice done it, because Apadhransa, like Misra, must be, even according to his explanation, a kind of mixed language or jargon.

1. The Sanscrit, called also *Gronthon*, from *Grandha*, book, is the holy language of the Bramins and of books. It is a dead language, but was probably once spoken; it is wonderfully perfect in its construction, and extremely copious. Its alphabet is called *Devanagari*, divine alphabet, because it is said to have had its origin from the gods, whose language it is; it consists of fifty letters. It has three genders, a dual like the Greek, conjugations numbered according to the vowel or consonant endings, seven cases, instead of pronouns, after nouns, and abundance of particles. Its flourishing period was at the court of Vicramaditya, rajah of Benares, in the last century before the Christian era, where the celebrated poet Calydas lived, the author of *Sacontala*, or the Fatal Ring, and of the *Megha Duta*, or the Cloud of Message. In this language are also written the old sacred books, the Vedas. The father of Sanscrit grammar is Panini, whose name occurs in the Indian theogony, and to whom are attributed the *Sutras*, or short grammatical precepts; although he himself refers to predecessors, as Samkyn, Gargyn, Casyapa, Galava, Sacatayana, &c. But his system is very artificial. His work was improved by another ancient philosopher, Catugayana, in his *Varticas*, explained by Patanjali, a mythological personage in the form of a serpent, in a work entitled *Mahabhashia*, which again received additions from Caiyata, and from an unknown person in the work entitled *Casica Vritti*. This last work is highly esteemed, and gave rise to the commentary *Padamanjari*, by Haradatta Misra. A second grammar is Ramachandra's *Pracriyacaumudi*. Modern ones have been written by Wilkins and Colebrooke. The *Amara cosha*, or the Treasure of Amara Singa, who lived before the Christian era, is a dictionary of the Sanscrit. A supplement has been given by Medicinar, in his work *Medini*. *Vistrapracasa* by Maheswara, is a second dictionary: *Haravali*, by Purushottama, a third. There are many others, as by Ilagudhu, *Vachespatis* the *Dharanicosha*, Bhattaji's *Siddhanta caumudi*, *Praeriga caumudi*. A Sanscrit press was established at Calcutta in 1808. Sir William Jones, the learned president at Calcutta, to whom the cultivation of Oriental literature is so much indebted, was well acquainted with the Sanscrit. It may be called the fundamental language, as it contains the original and fundamental sounds of all the European languages, and not merely in a superficial resemblance; so that by means of it are manifested that great fellowship and affinity, by virtue of which all languages form one great growth of the mind.

11. The Pracrit, as the common language, comprehends the various dialects used in writing and social intercourse. Ten are named by Colebrooke, to which, however, should be added the Penjabi and Brijja Bhasha. They are spoken in the fertile provinces of Hindoostan and Deccan, by the—1. Sareswata, a people on the banks of the river of this name, which flows through Penjap. This dialect is especially used in dramas and poems. 2. The Kanyacubjas, whose capital was Canoge. It seems to be the present Hindi or Hindoostanee, except that the latter contains Persian and Arabic words. These two dialects are written with the Devanagari alphabet. 3. The Gauras of Bengal, whose capital was

Gaur. This is the Bengalee or Bengal dialect, which is spoken chiefly in the eastern parts of Hindoostan. Many Sanscrit poems have been translated into this dialect; the learned Hindoos speak it almost exclusively. Its characters are the Devanagari, somewhat altered, for convenience. 4. The Mitilaw, or Tirhoot, is the prevalent dialect in Mitilaw, or the Circar (Circle) of Tirhoot and some neighbouring districts, bounded by the rivers Cusi and Gandhac and the Nepal mountains. It is not adapted to poetry. 5. The dialect of Utcala or Odradesa (Orissa) is called *Uriya*, and has Sanscrit words. The five above-named dialects are the languages of the five Gaurs, or of Northern Hindoostan. The five following are those of the five Dravids, and are called *Tamul*. They are—6. the Dravida, the southern extremity of the Deccan, where the *Tamul*, called also by the Europeans *Malabar* (though the former is rather the eastern dialect, the latter the western) is spoken; the former is spoken from cape Comorin under the Eastern Ghauts northwardly as far as Pullicate, the latter from cape Comorin, as far as Goa; they meet at the cape of Coimbatore. The gospel is preached by Christian missionaries at Madras, Tranquebar, and Tanjore, in the *Tamul*. Ziegenbalg translated the Bible into it. The name *Tamul*, as the natives pronounce it, is probably connected with the river *Tamraparni*. 7. The Maharashtra, or Maharrata, is spoken on the northern part of the plateau of the Deccan, eastward of the highlands of Omercuntuk. *Murn*, as this country, situated between the Nerbudda and the Krishna, was formerly called, was the centre of the Dravids, whose capital, Dwara Summadra, was destroyed in 1326. This dialect is written with the Devanagari, and has, likewise, many Sanscrit words. A grammar and dictionary were published by Carey, in 1809. 8. Carnata, or Carnara, by corruption Canara, in the middle of the plateau of Mysore, consequently in the middle of the Deccan. It is still spoken in the mountainous regions, but on the eastern coast has been supplanted by other dialects. 9. Tailanga, Telinga, or Tilanga, also the Andray, the language of a people in the north-east of the peninsula, between the Krishna river and Godavery, as far as the northern Circars, and reaching southward to Pullicate. It has much resemblance to the Sanscrit, and has a separate alphabet, called *Calanga*. 10. The dialect of Gurjara or Guserat, Gestira, a peninsula in the west, is the last dialect of the Pracrit. A dictionary of it has been compiled by Drummond.

III. The Paisachii, or Apadhransa, probably the language of the mountaineers, in dramatic poetry is the language of demons, a jargon mixed with Sanscrit, and therefore the language of ridicule.

IV. The Magadhi, or Misra, probably the Pali and Magadhi of the island of Ceylon, used by the priests of Buddha. It is called *Misra*, because it is intermingled with Sanscrit words. It also generally designates the foreign languages, introduced by the conquerors of the countries on the Indus and Ganges, especially those of the Indo-Chinese. Doctor Leyden thought to have discovered in it many original languages, which might, indeed, have had a common foundation (according to Vater, the Chinese). The foundation of this system of languages is monosyllabic, and, as in the Chinese, the different intonations determine the meaning. Those of the islanders are polysyllabic, those of the mainland monosyllabic. The monosyllabic disappears near Bengal. To the east, it is more common, and prevails exclusively in Cochin-China and Tonquin. They are given in the following order:—1. Polysyllabic; a. Malay; b. Javanese; c. Bugis; d. Bima; e. Batta; f. Gala, or Tagala. 2. The monosyllabic; g. Rukheng; A.

Barma; i. Mon; k. Thay; l. Khohmen; m. Law; n. Aman. Sir W. Jones first perceived the Sanscrit in the language of the Malays, though it is not the only basis, but is joined with a foreign element. In it are written the tales of the Pandus, taken from the old Sanscrit epic Mahabharat. A grammar and dictionary of it were published by W. Marsden. There is another dictionary by James Howson. The Javanese resembles the Malay very much. Doctor Leyden considered the Pali or Bali a dialect of it, which may be, perhaps, a language common to all the countries between the eastern and western boundaries, the language of their holy books, of their priests, scholars, and poets. The Rukheng in Arracan, to the west, is said to bear much resemblance to the Devanagari in its characters, and to the Sanscrit in its structure and mythology. The Barma is softer but less articulate than the Rukheng, but it is very perfect, and has a rich literature. The Mon is still prevalent among the inhabitants of Pegu, who style themselves *Mon*, but are called by the Barmas, *Taleing*, and by the Siamese, *Ming-Mon*. Their alphabet is the Barma-Bali alphabet a little altered. Thay is the language of the Siamese. The Barmas call the country *Syan*, whence, probably, the Portuguese Siam. The Khohmen is the language of a nation on the Mecon or the Cambodia, which is regarded as very learned, and was formerly subjected by the Siamese tribe. The Law is the language of the people called by the Portuguese *Laos*. According to Leyden, it stands in the same relation to the Thay, that the Barma does to the Rukheng, though it bears a closer affinity to the common Bali. In this central country of Laos are the most remarkable monuments of Buddaism; and probably it will hereafter afford, on this point, much information. As the Sanscrit is the common centre of the Hindoo languages, so is the Bali of the Indo-Chinese. In the country between India and China, it is the language of religion, of the law, of science and literature, and appears in all the languages of the people. It is also called *Lankabasa*, i. e. the language (in Greek *Βαλ*) of Lanka, or Ceylon and Megata, or Mungata, perhaps analogous to the Sanscrit Magadhi. The Bali alphabet had its rise in the Devanagari, but differs essentially from it. The form of the Bali character among the Barmas, is quadrangular, very much as in Lanka, but different from the Siamese, which is called *Nungun-Khom*. It has all the Sanscrit inflexions of verbs and nouns, though it more rarely uses them in connexion, and more frequently uses the past participle and impersonal verbs. Then the Pracrit, Bali, and Zend, as Sir W. Jones very acutely observed, again come into affinity, as three dialects of the Sanscrit. They have had very much the same fate. Pracrit is the language of most of the holy books of the Jaina sect; Bali is the sacred language of the Buddhists; Zend of the Parsees, or fire worshippers. A wide and deep survey of the whole variety of Indian language, primitive, mother, and mixed, would afford the most interesting information respecting the philosophy of language and religion.

*Indian Literature.* Europe still lay in the deepest slumber, when Hindoostan was already in possession of art and science. A thousand years before Christ, a tender and imaginative poetry existed there, and the immense rock on which her mythology is sculptured, is a work, in comparison with which the pyramids of Egypt seem young. The astronomical knowledge of India, existing before the period to which history extends, the antiquity ascribed to the alphabet, the language, the religious traditions, handed down by means of pictures and writings—all point to a development of the human intellect.

from its first germ. Mental culture begins before literature. The latter, in India, appears first in theology; afterwards, when the occupations of life became more distinct, it became also a profane art, a vehicle for historical or natural knowledge, down to the time when poetry was written, which naturally returned to mythology. This general division into sacred and profane literature we intend to observe.—We first remark, in respect to the arts of writing among the Hindoos, that they are acquainted with paper, though it is not made of cotton, but from the bark of a shrub whose fibres are carefully separated. The former discovery is of later date, being first made after the invasion of the country by the Mongols. When this coarse paper cannot be had, a white crayon is used, with black tablets. The usual material, however, is the leaf of the fan-palm, which, being about three fingers broad and two feet long, contains seven or eight lines; and, as it is thicker, stronger, and stiffer than double paper, it admits of writing on both sides. This is done with an iron style, six inches in length, and sharpened at the upper end to make the leaves very smooth. The leaf rests on the middle finger of the left hand, and is held between the thumb and forefinger. The right hand does not move over the leaf, but, after a writing a word or two, the writer presses the style deeper into the last letter, and moves the leaf from the right to the left. The Hindoos are so accustomed to this method, that they write while walking. As these marks are very fine, the leaf is rubbed with fresh cow-dung, in such a manner that only the finest particles of it adhere to the lines, and it is then done over with black. The Hindoos do not write on paper with a quill, but with a reed (*calamus*), which is split like our pen, but is stronger. To form a number of palm leaves into a book, a hole is made through both ends of the leaves, and they are fastened together by a small thread. Two thin pieces of wood, of the size of the leaves, are then placed above and below; a hole is made at each end, and pegs of wood or iron are passed through the whole, to fasten all the parts together. A long string is fastened to the peg, which is wound round the book a number of times. We now proceed to the literature of the Hindoos.

1. *Sacred Literature.* We possess this under the general names of *Shashtra*, *Shaster*, *Sistra*, *Shastu* (the different forms of this word are unquestionably merely differences of dialect); i. e., holy, ordinances given by God. They can be read only by the three first, or regenerated castes. The Hindoo has received the sacred writings as religious documents, as the word of God, from God, from Vishnu, the metamorphosed Vyasa, and the books themselves are called *Vedas*. Both these words, *vyasa* and *veda*, belong to the same family, the members of which signify *knowledge*, *wit*, *law*, *ordinance*, and are derived from a root whose original signification is *light* and *fire*. Vyasa, however, found the word of God already existing, and was, consequently, only a collector of the Vedas, which he reduced to four divisions, called *Rig*, *Ritch*, *Jayush*, *Saman*, and *Atharvana*. The first division is metrical, the second in prose, and the third consists of prayers, designed to be sung. The last are prayers to be used with purifications, expiatory sacrifices and maledictions, and differ materially from the others, on which account their genuineness has been doubted. These *Vedas* are properly the original text, which has given rise to several expositions: the latter, in turn, are esteemed holy, like the Talmud among the Jews. Each *Veda* consists of two parts—the *Mantras*, or prayers, and the *Brahmanas*, or commandments. The whole body of hymns, prayers, and invocations in one *Veda* is called *Samhita*. The commandments inculcate religious duties,

moral maxims, and theological doctrines. The proper Hindoo theology is contained in the part which unfolds Upnaishada's revelations (of the same family as the Low German *open*, the Greek *ων*, an opening), and consists of explanations of mysteries. Anquetil du Perron has published these, under the name of *Oupnekhat*, in a Latin translation of a Persian abstract, which was itself corrupted, and which he also misunderstood (Strasburg, 1801, 2 vols., 4to.) The *Vedas* are in Sanscrit, in the Devanagari. (See *Indian Languages*.) A British officer, who lived a long time in India, enriched the British museum with a complete copy of the *Vedas*, in eleven volumes. A second class of sacred books are the *Upavedas*, in four parts (*Ayush*, *Gandharva*, *Dhanush*, and *Shapatya*), treatises on surgery, medicine, music, dancing, war, architecture, and many mechanical arts. The third class are the *Angas*, or *Bedungas*, in six parts (*Sicsha*, *Calpa*, *Vyacarana*, *Ch'handes*, *Iyotish*, and *Nirukti*), treating of language and grammar, prosody, poetry, astronomy, the ritual, and difficult words in the *Vedas*. The fourth class are the *Upanishads*. They are divided into three classes—the *Puranas*, *Dharmashastras*, and *Dersanas*. The *Puranas*, to the number of eighteen, with as many *Upapuranas*, supplements and explanations, treat of mythical philosophical subjects, viz., cosmogony, theogony, &c., a more extensive series of legends, which sometimes, of course, represent the great relations of the world and time, under a contracted view, but cannot be rashly rejected. We will merely enumerate the *Puranas*:—1. *Kalika Purana*, a history of the goddess Kalika Parvadi, Bhavani, the wife of Siva; 2. *Abhiatma Ramayana*, a fragment of the *Brahmanda Purana*, a history of Ramatshandra; 3. *Brahma Vairartika Purana*, the origin of the gods, and the history of Ganesa, Crishna, Durga; 4. *Pedma Purana*, in praise of the lotus (*pedma*), and a history of Lakshmi, the wife of Vishnu, in 55,000 stanzas; 5. *Agru Purana*, a sketch of all Indian science, in 15,500 stanzas; 6. *Vishnu Purana*, in 23,000 stanzas; 7. *Siva Purana*, in 24,000 stanzas; 8. *Linga Purana*, in 11,000 stanzas; 9. *Scanda Purana*, of the god Scanda, the son of Siva and Bhavani; 10. *Haritalika and Savriti Bata* relate to religious customs; 11. *Ontkal Khanda* and *Kasi Khanda*, the former a description of Orissa and the old religious rites of the Vishnu worship at Juggernaut, here *Poursatim*; the latter a history of the city of Kasi or Varanasi, now *Benares*, the principal city of the Sivaites; 12. *Nuradeya Purana*, the history of Nareda, god of music, in 25,000 stanzas; 13. *Markandeya Purana*; 14. *Bhavisira Purana*; 15. *Vayu Purana*, the history of Vayu, god of the winds; 16. *Matsya Purana*, the history of Vishnu, as the fish in the first deluge, in 14,000 stanzas; 17. *Narasingha Purana*, Vishnu as a man-lion; 18. *Vhagavata Purana*, the work of Vyasa, the history of Crishna, or rather of Vishnu, in twelve books, containing 18,000 stanzas, which have been published in French and German. The two oldest and most important epic poems are—19. *Ramayana*, the history of Ramatshandra, king of Ayodyia, the seventh great incarnation of Vishnu—a work of Valmiki; 20. *Mahabharata*, the war of the Pandus and Kurus, two lines of descendants of the old Indian king Bharata, in eighteen books, and more than 100,000 stanzas. Wilkins, Parrand, Proben, Herder, Schlegel, and Majer have translated an episode from this work, called *Bhagavat Gita*. Another, entitled *Nalus* (published at Paris and Strasburg, in the original, with a Latin translation), has been translated into German by Bopp and Kosegarten (Jena, 1820). To the *Dharma Shastras*, as the second division of the *Upanishads*, belongs the *Munava Dharmastra*, or the ordinances of Menou (English, by

Sir William Jones)—a complete code of laws and customs, containing a poetical account of God and the spirits, of the creation of the world and of men (Schlegel's *History of Ancient and Modern Literature*, i. 171). The *Dersana*—the third class of the *Upangas*—are philosophical works, and are of three classes—*Nyaya* (connected with the Greek *Nous*, understanding, mind), which explains the sense of separate passages of the *Veda*, and is divided into two parts—the work of Gotama and Cadana; *Sankhya*, which is twofold, either with or without *Isvara*, and *Sankhya*; the first is also called *Patanjala*; lastly, *Mimansa*, which is again attributed to *Dvapajana*, surnamed *Vyasa*, or the Compiler. Dow has published parts of the *Dersanas*.

2. *Profane Literature*. We shall only touch upon some of the principal works. *Mughabodha*, or the Beauty of Knowledge, by Goswami, surnamed *Vopadeva*, is considered the best Sanscrit grammar. There is another, by Kalapa, called *Katantra Vriti*, with an etymological commentary, called *Katantra Vriti Tika*. Such commentaries are also *Dowrga Singha*, *Tritatthandrasa*. Another grammar, with the title *Sankhitya Sara*, by Radjah Djoumoura Randi, has been commented on by Gopi Tchandra. The best dictionary, *Amarasinha*, has been already mentioned; besides this, there are seventeen others, of great reputation. The Hindoo poetry has, throughout, an elegiac earnestness and sweetness, which owes its origin to their oldest poet, Valmiki, who sang in plaintive strains of the murder of a youth, who lived happily with his mistress in a beautiful wilderness, and was mourned by her in heart-rending lamentations. We have already spoken of Valmiki as the author of the epic *Ramayana*, with which Vyasa's *Mahabharat* alone can be compared. Another poet is Djana Radjah, who has described the meeting of Arjoun with Siva. Bhattu Bana, a third poet, is the author of *Kadambari*. Bharti Hera Pandita wrote a popular epic *Bhakti: Djaga Deva* wrote the *Gita Govinda*—a hymn to Govinda (translated by Jones). The dramas, called *Nataka* by the Indians, are numerous. Among the dramatic poets, Calicás, a poet at the court of Vicramaditya, about a century B. C., is mentioned as a star of the first magnitude. He has been called the *Indian Shakespeare*. His best drama is *Sacantala*, or the Fatal Ring, an English translation of which has been made by Jones, and a German by Forster, and of which Herder says—"All the scenes are connected by flowery bands; each grows out of the subject as naturally as a beautiful plant. A multitude of sublime as well as tender ideas are found in it, which we should look for in vain in a Grecian drama." *Koumava Samblava* (the Birth of Kumara, the Physician of the Gods) is one of the productions of this poet, as likewise *Ourcasi Vikrama* (the Heroism of Urvasi), in five acts, and *Megha Duta*, or the Cloud of Message, published by Wilkins. Among other Hindoo dramas are *Ketriabali* (the Pearl Necklace), by Hirsadeva; *Prabodha Tchandra Oudaya* (or the Rising Moon of Knowledge), in six acts, by Krishna Misra; *Hasiarnava* (or the Sea of Ridicule)—a satirical drama, in Sanscrit and Pracrit, by Djayadeswara Bhattacharia; *Maha Nataka*, the great drama, also in Sanscrit and Pracrit, by Madhusanada Misra Murari, in seven acts. *Mudra Rakhyasa*, and *Malati*, and *Malhera*, dramas in ten acts, are by unknown authors. (See Wilson's *Hindoo Drama*, Calcutta, 1827). The poetical treasures of the literature have been not a little increased of late by the establishment of a printing press at Calcutta, for the purpose of publishing Oriental works. The Hindoos have two kinds of feet (*padam* or *charanam*) in their verses—the simple *ganam* and the *upaganam*. Of the former, there are eight,

called, in general, *majabasanarayala*. They are the following: *maganam* (molossus), *baganam* (dactyle), *iaganam* (amphibrachys), *saganam* (anapest), *naganam* (tribrachys), *raganam* (creticus), *yaganam* (palingbaccius), and *laganam* (baccius). The *upaganams*, called *yarahaganagananala*, are *gaganam* (spoon-dee), *haganam* (trochee), *vaganam* (ambus), *nakan* (proceleusmaticus), *galam* (pyrrichius), *melagu* (epitritus quartus), *nagam* (preon quartus), *latam* (ioniacus minor). The Hindoos have also two kinds of rhyme: the one falls on the first letter or first syllable of the verse, and is called *yety*, or *vadi*; for example, *As in kirti* and *kirtana* makes a rhyme. The other falls on the second letter or the second syllable from the commencement, and is called *prasanam*; for example, *pa* in *Capaguy* and *Dipantram*. Of the verse, the *schlocken*, a stanza or strophe, has already been mentioned. But there are also other kinds of verse (*padayams*), as the *caudapadayan*. There are five writers on prosody, which is very difficult. The oldest philosophical sect is considered to be that of Capila. The philosophy called *nyaya* (see above) is a kind of logic containing the doctrine of syllogisms, which, according to a Persian account of Mohammi Fani, is the foundation of that of Aristotle. A third system is the *mimansa* (which reminds us of the monkey and serpent god), invented by Vyasa (see above), and improved by his scholar, Jaimini. Vyasa's doctrine is called *vedanta* (the aim of the *Vedas*). It teaches the dependence of matter on mind. The disciples of Buddha, on the contrary, are materialists. Thus we have three systems, the *Vedanta*, the *Nyaya*, and the *Mimansa* mythologically developed, as pantheism, in its noblest sense, with the corresponding views of idealism and realism. The Sankhyas, Jains, and other sects, are unquestionably later followers of one or the other of these systems. We will only name some of the philosophical works. Among them are *Gangheswara Fatwa Schirtamani*—a treatise on metaphysics; *Pratikhya Tippani*—a commentary on visible objects, by Gadadhara, who also wrote on moral cases and moral power; *Gouna Bharu*, or concerning qualities of things; *Anumaka Didhati*, or a treatise on memory, by Siromini Battatcharia; *Smriti Tattva*, or an Abstract from the Laws, collected by Ragunanaka Bhattacharia (translated into German by Raspe); *Hitopadesa*, Friendly Instructions—a Hindoo book of fables (published by Wilkins), called also the *Fables of Pilpay*. Hindoo literature first began to be extensively cultivated in Europe, at the commencement of the present century, and the study of it can as yet be considered only in its infancy. The first great work published in Europe, in the ancient Indian language, was *Hitopadesa* (1810). In 1808 appeared Wilkins's grammar, published with the types which have been used by Bopp. See the papers of Jones, Wilkins, Wilson, Ellis, Colebrooke, and others, in the *Asiatic Researches* (15 vols., Calcutta, 1788—1828), and in the *Trans. of the Royal Asiatic Society*, London.

*Indian Mythology*. Divine rest, immersion or absorption in the Godhead, is considered by the Hindoos the highest perfection; and the way which leads to it is the sacrifice of the individual self. The religious doctrines of the Hindoos are contained in the four *Vedas*, of which the six *Angas* are commentaries, by the Brahmins; the second commentary, called the *Angutorrah Bhade Schasta*, in eight books, containing fables and allegories, and a ritual, makes the number of holy books eighteen; there are four *Upavedas* and four *Upangas*, which include the eighteen *Puranas*, *Nyaya*, *Mimansa*, and *Dharma-shastra*. (See *Indian Literature*.) Thus the *Vedas* are the Bible, the *Puranas*, the Mythology, the historical poetry, *Dharma Shastra*, the ethics, and the

other two the orthodox philosophy. These parables introduced dissension, and new religious writings appeared, according to Gorres, probably the Bali writings, the books of Buddha, in Malabar and Comorandel. These books, rejected by the orthodox Brahmins on the Ganges, are the basis of six systems of philosophy, viz., Jogachara, Sandhata, Vaitaschica, Madyamica, Digambara, and Charva. Although a continual change may be thus perceived, and a world of fables, continually growing more and more variegated, was opened, yet the foundation always remained the same, and Bramaism and Buddhism remained essentially unchanged. The Hindoo religion is, therefore, Pantheism, understanding by that word a religion which inculcates the belief in One existing in all things, and all things existing in One—God in the universe, and the universe in God, and regards nature as a revelation of the divine intelligence. Every thing is thus the continual transformation (metamorphosis) of God. This fundamental doctrine is inculcated in various ways by all their writings on religious subjects; and upon this doctrine rests the idea of the reciprocal influence of worlds upon each other, and their central light, and the conception of the universe as a perpetual creation, as does, likewise, the belief in metempsychosis, or the transigrations of souls after death. The sins of the parents are considered to be visited on their children, because the son is the father regenerated. Beginning and end are mingled, and mind and matter are continually striving for predominance in the universe, which therefore exhibits a never-ending struggle between good and evil, light and darkness. The original Hindoo conception of God, the omnipresent Being, in all his purity, eternity, and spirituality, and beatitude, is pure and elevated; he is called *Brahm*, *Atma* (the breathing soul), *Bram-atma*. Before the creation, he reposed in silence, and absorbed in himself. This world, says Menou, was all darkness undiscernible, undistinguishable altogether, as in profound sleep, till the self-evident invisible God, making it manifest with five elements and other glorious forms, perfectly dispelled the gloom. He, desiring to raise up various creatures by an emanation from his own glory, first created the waters, and impressed them with the power of motion; by that power was produced a golden egg, blazing like a thousand suns, in which was born *Brahma*, self-existing, the great parent of all rational beings. The Hindoos, says Sir W. Jones, worship the Supreme Being under three forms—Vishnu, Siva, *Brahma*; for that is the order in which the three are expressed by the letters A, U, M, which coalesce and form the mystical word *Om*, which never escapes the lips of a pious Hindoo, but is meditated on in silence. The learned Indians, as they are instructed by their own books, in truth acknowledge but one Supreme Being, whom they call *Brahm* or the Great One, in the neuter gender; they suppose his essence to be infinitely removed from the comprehension of any mind but his own, and they suppose him to manifest his power by the operation of his Divine Spirit, whom they name *Vishnu*, the Pervader, and *Agayen*, or Moving on the Waters, both in the masculine gender, whence he is often denominated the first male; and by this power they believe that the whole order of nature is preserved and supported; but the Vedantis, unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of Supreme Goodness was left a moment to itself, imagine that the Deity is ever present to his work, and constantly supports a series of perceptions, which, in one sense, they call illusions, though they cannot but admire the reality of all created forms, as far as the happiness of creatures

can be affected by them. When they consider the divine power exerted in creating, they call him *Brahma*, in the masculine gender also; and when they view him as the destroyer, or rather changer of forms, they give him a thousand names—Siva, Iswara, Mahadeva, &c. The first operations of these three powers are described in the Puranas, by a number of allegories, and from them we may deduce the Ionian philosophy of primeval water, the doctrine of the mundane egg, and the veneration paid to the nymphæ or lotos, which was anciently revered in Egypt, as it is at present in Hindoostan, Thibet, and Nepaul. The fundamental idea of the Hindoo religion, that of metamorphoses, or transformations, is exemplified in the Avatars. The Avatars are transformations of Vishnu, and are interesting as an extremely rich cycle of mythology. These transformations fill up the Indian Yugs, which compose a certain series of periods intended to effect a junction with God, and comprising 4,320,000 years. The Yugs have been considered as an allegorical description of the year, divided by the solstices and equinoxes, and of the precession of the equinoxes. The Avatars are generally considered as ten, though others give more, which, however, are of inferior importance. The five first are these:—1. Mat-yavata, the transformation into a fish, the deceptive Maya-fish. *Brahma* one day fell asleep; the giant Hayagriva (the rebellious, faithless human mind) stole the four Vedas (the universal law, given by *Brahma*), swallowed them, and concealed himself in the sea; *Vishnu* recovered them in the shape of a fish, and thus annihilated the empire of the evil one; for that incarnation had for its object and consequence the salvation of the world from the power of evil. 2. Kurma-avatara is *Vishnu*'s transformation into a tortoise, sustaining the universe, which had been convulsed by the assaults of demons, while the gods churned the sea with the mountain Mandar, to force it to disgorge the sacred things and animals, together with the water of life, which it had swallowed. 3. Varaha-avatara, the transformation into a boar. The giant Hiranyakshana (the giant of the earth) had coiled up the earth like a cable, and concealed it in the Patalas, seven subterraneous worlds. *Vishnu*, as a boar, rooted up the earth with his tusks of fire. 4. Narasingha-avatara, the transformation into the man-lion. In a contest with the giant Hiranyaksha (also Eru-niakassiben), *Vishnu* appeared as a man-lion from Siva's pillars of fire, and saved the son of the giant, who, pursued by his father, had taken refuge behind the pillar. This is another version of the earth-forming conflict of water and fire, as the name of the metamorphosis (*Narasingha*), and of the festival of this incarnation (*Neriosengh*), denotes; for *nar* is, in Indian, water; *narasayana*, the movement in water; and the words *seng*, *zeng* (to scorch), imply the idea of fire. 5. Vamana-avatara, transformation into the Brama, or Lingam dwarf. In the shape of a dwarf, *Vishnu* visited the giant Bali, who had done the gods much harm, and requested of him as much land as he could cover with three paces, whereon to sacrifice. The giant having promised it, *Vishnu* immediately resumed his divine form, with one step covered the whole earth, and with another the whole space between heaven and earth, upon which the giant submitted, adored him, and was sent to govern in Padalon (the infernal regions). It is unnecessary to describe the remainder of this series of transformations.—Among a people of such exuberant fancy as the Hindoos, it is natural that every thing should receive form and life. But it is remarkable to what a degree their works of imagination are pervaded by the idea of sexuality. Sir William Jones remarks, that "it never seems to have entered into the heads of the

Hindoo legislators, or people, that any thing natural could be offensively obscene—a singularity which pervades all their writings and conversation, but is no proof of the depravity of their morals." Thence the worship of the Lingam by the Sivanites, of the Yoni by the Vishnuvites. Lingam is the symbol of the male nature. The worship is thus historically derived. Siva, by his voluptuousness, gave offence to seven penitents, and by their maledictions lost his virility; but, the punishment having been subsequently deemed out of proportion to the transgression, the penitents resolved to worship what they had previously cursed. It is worshipped in temples, roads, &c. Yoni is the feminine with the masculine, in a figure, which is also written with cow-dung on the forehead. Moreover, like the eye, plants were, in this mythology, symbols of perception and regeneration; and plants and the eye, forming a triangle, were united in the flower called *lotos*. In language, *lotos* is the flower of concealment, of night, of silence. In natural history, it is the *nymphaea nilufer* (Lin.), in India called by various names—*padma*, *panceruha*, *tamarasa*, *nalina*, *aravinda*, *maholpala*, *camala*, *cushaya*, *sahasrapatra*, *sarasa*, *sarasiruha*, *rajiva*, *visvaprasuna*, *pushcara ambhanika*, *satrapa*. Its seed is abundant, small, and round; it is either blue or red; the flowers of the former are a beautiful blue, but, if entirely unfolded, somewhat less fragrant than the red rose-coloured species, though of a very fine odour. The leaves spring directly from the roots, deeply indented; on one side dark purple, reticulated; on the other, green and soft; the petals very soft, long, and reed-shaped. There is also a variety with the leaves purple on both sides; dark crimson flowers; the chalice leaves richly coloured within, and broad anthers; less acute and broader than the blue, with little odour. The worship of the *lotos* is still practised, as devoutly as ever, in Hindoostan, Tibet, and Nepal. Temples are decked with it, as are also deities; for a god, immediately after his birth, always floats in the water on a *lotos*. The Hindoos adore it because it is a water plant, and water is the vehicle of creation. It is also sacred among the Egyptians. As every thing in India appears in the glow of life, and is endowed with form, the moon, and sun, and stars have also their gods. All the starry worlds are considered as freeborn spirits and gods, which have become alienated and separated from the original light, the central sun of spirit, the Persian light-water, *Arduisur*; and from this light-water the milky-way has poured forth in streams of stars (*stars*). The adoration of fire, stars, or the sun, is therefore an ancient worship, as is that of water, too, in the above-mentioned idea. For that reason, Ganga (the river Ganges) is sacred to the Indians. It had its origin, according to one fable, from the sweat of Siva's wife, Paroadi, or, according to another, in the water in which the universe swims. The earth also has its goddess, *Prithivi*; the air its god, *Indra*, *Dewandra*, one of the eight placed as guardians of the earth by Vishnu, on his incarnation as a boar, which eight are *Indra*, *Aghni* (fire), *Padurbati* (Judge of the infernal world), *Nirurdi* (king of the infernal world), *Varuna* (water), *Maril* (wind), *Cubera* (riches), and *Eswara*, who in the east is *Indra*, in the south *Aghni*. The number of the *Devetas* (gods) is immense, and by some is rated at 333 millions. Of the inferior gods, or demons, we shall only mention the *Ginarers*, the genii of musical instruments, and the *Gandwars*, or *Gandharvas*, musicians of the air, who sing on the northern mountain of *Haimakutha* (the cold, the dark), the spirits of singing stars. These are good demons. The bad are called *Asoras*, or *Asors*, at whose head stand *Molmaoor* and *Rhadoon*, and they generally appear in a terrible, gigantic form; they inhabit the *Patala*,

or *Padalon* (the infernal regions). The universe is divided into fifteen districts, or circles, seven above the earth, called *Suega-Surge*, and seven below, called *Patala*. The *Patala* are lighted by eight carbuncles, on the heads of eight serpents. In the midst, between the two divisions, is *Mirtlok*. The ceremonies of Hindoo worship consist of visits to the pagodas, ablutions and purifications, penance and mortifications, good works, sacrifices, &c. Some of their pagodas are of high antiquity and gigantic conception, majestic appearance and tasteful architecture. The entrance is always made in a huge pyramid, which gradually grows narrow as it approaches the top, where it runs out into a half moon. The pyramid faces the east. In large pagodas, there is always a spacious court, and, at its end a gate corresponding to the first, excepting that the pyramid is not so high. Opposite the door, in the middle of the second court, is placed on a pedestal, or in a cavity of the wall, between four pillars, a cow, lying down; sometimes a lingam, Hanuman, serpent, or some other object of adoration. *Sahatangam* is the name of the custom of falling on the face; *samashtaram*, of the folding and raising of the hands to the forehead. The edifice is divided into two or three parts, of which the one is large, the other, for the sacrifices, smaller; the whole is formed of tiles, or unhewn stone. On the Coromandel coast, there are more splendid temples than in Bengal; on the Malabar coast, the style of construction is different. The most celebrated pagodas are those of Elephanta and Salsette; those of Illura, or Elora (q. v.); the temples of Vishnu at Tirupadi, Schirangam, Kaangiwarum, and the temples of Siva at Tirunamalai, Tirvatar, and Shalembron, Kandschipuram, Ramonathampuram, Ramischwarum, and Caschi. The pagoda at Elephanta, or Kalpuri, is considered as the oldest, and derives the first name from an elephant hewn on black stone, at the foot of a mountain, on the side of Bombay. Several pagodas are there collected together. The cisterns now used for watering could were formerly appropriated to purifications. The temples at Elora are hewn out of a chain of hills, in the shape of a horse-shoe, and form a kind of Indian pantheon. All the deities have there a temple, great or small, and some of them a number. Two of the largest are consecrated to the Trimurti. It is a colossal hieroglyph, and, like the pyramids, bears witness to the absorbing influence of religion in ancient times. Jagrenat's or Krishna's three pagodas, at Jagrenat, whose towers are seen from the sea at twenty miles' distance, and to reach which it is necessary to go through a multitude of small pagodas, with consecrated groves and ponds, are surrounded by an immense, thick, square wall of black stone. The image of the god is placed on the summit. It derives great revenues from pilgrims. For the abbot's previous to every act of worship, any water is good, provided it be running, and especially that of the Ganges. There are, therefore, ponds at all the temples, unless these are situated on a river. Cow-dung may be substituted for water, in the performance of the ceremony. Passages from the Vedas, Vedangas, etc., are first read. The idols are also washed with water and with milk, and anointed with butter and costly oils. Penance is either of the *contemplative* kind, in which the penitent must mortify the appetites, in order to devote himself wholly to the contemplation of the divine nature, and be united with God, or of the *expiatory* kind. The penitent form, in some degree, monastic orders; and Fakirs, Jogueys, Atits, Vairagis and Tapis, up to Varnaprashnas and Sanyasis, are the living images of penance. Good works consist in donations of cattle, or other things, on festivals and solemn occasions. The principal

offerings are the following:—the Jaga, or Jagum, consecrated to the sun and the nine planets, is a burnt-offering, in order to obtain the holy fire, with which the funeral piles of departed Brahmans may be kindled, in order to exempt them from further penance after death, and translate them from the ashes to the courts of Brahma. It requires great preparations. A hundred learned Brahmans select a place, which must be consecrated by prayer and holy water; a large tent is then erected in the middle, and around it several small ones; in the large one is a square floor, from the centre of which rises a wooden pillar, with a cord fastened at the top, the two ends of the cord hanging down; around lie nine kinds of wood, particularly holy, of which also the priests hold each a piece in their hands. Pieces of arasa wood are then rubbed together till they take fire; after which a he-goat, or ram, without blemish, is brought into the circle, and various magic words whispered in his ear; after which he is strangled; his liver is taken out, washed with milk, besmeared with butter, and roasted by the sun and fire, but the animal itself is burned; the liver is divided among the Brahmans, and eaten; the high priest takes the sacred fire home with him. Homa, or Homan, is a sacrifice made to Agni, the god of fire; it is called, in distinction, *Drauyagna* (the divine sacrifice), and is offered on the occasion of all important undertakings. A purified Brahmin, clothed in white, takes a seat on a wooden stool, and repeats some *schloken* (stanzas); before him are placed a bell, a burning torch, and a vessel of liquid butter, or cocoa-nut oil; at his sides large banana leaves, on which the things to be sacrificed are deposited round the altar, e. g. eagle-wood, branches of the camphor tree, red sandal, *amree*, &c. This wood is set on fire, the bells rung over it, butter is poured into the fire, and then rice, plants, &c., are thrown in and burned, while prayers are repeated; several cocks are killed, and, reeking with blood, thrown into the air; an iron hook is then thrust through the back of some pious man, on which he is swung and borne about, amid acclamations, shouts, and benedictions. *Pidrajagna* is an expiatory offering for the deceased. *Bhudagagna* is an offering rendered to the spirits of evil. *Adithipugia* is the offering of united friends; in this rite, the image of the common deity is placed in the court of the house, strewed with flowers, amid the prayers of the two friends, and the feet of the stranger are washed. *Arika* is an offering of flowers for the happiness of souls. The *Mahabharata* (translated by Wilkins) is said to contain all the great mysteries of the religion of the Brahmans. (See the work of William von Humboldt, *Über die west. d. N. Bhagavad-Gita bekannte Epochen des Mahabharata* (Berlin, 1826) Poliers' *Mythologie des Indous* (1800) has too little credibility to be used as an authority. We refer the reader to the *Mœurs, Institutions et Cérémonies des Peuples de l'Inde*, by the abbé Dubois, who lived upwards of thirty years among the Indian castes (Paris, 1825, 2 vols.). There is a sect among the Hindoos, which styles itself *Saouder* (worshippers of God), rejects the worship of idols, and offers nothing but religious hymns to the Divine Being. These Indian Quakers are required to abstain from luxury, from dancing, wine, tobacco, and are forbidden to offer violence to man or beast; they are enjoined to practise industry, and giving in secret, and prayer; they are regular and obedient citizens, and mostly merchants.

INDIAN CHRONOLOGY. See *Epoch*.

INDIAN CORN. See *Maize*.

INDIAN OCEAN; that great body of water, which has Asia on the north, the Sunda isles and New Holland on the east, Africa on the west, and the Antarctic ocean on the south. The cape of Good

Hope, in 21° 27' E. lon., and the southern extremity of Van Diemen's Land, 147° 26' E. lon., may be considered its extreme limits from east to west. Its length, from north to south, is about 2400 leagues; its breadth varies from 2200 to 1200 leagues. Its principal gulfs are the Red sea, the Arabian sea, and the bay of Bengal. Its islands are Ceylon, Madagascar, the Laccadives, Maldives, Socotra, Andaman, Nicobar, the Isles of France and of Bourbon, Kerguelen's Land, &c. Numerous rocks, and coral reefs, render the navigation dangerous. The Ganges, Burrampooter, Irawaddy, Indus, Euphrates, empty the accumulated waters of Southern Asia into the Indian ocean. The trade-winds prevail here between the tropic of Capricorn and the 10th degree of south latitude; to the north of this region the monsoons are felt.

INDIAN RUBBER. See *Caoutchouc*.

INDIANS; a name common to the aborigines of the American continent. We can give no opinion respecting their origin. The only hypothesis on this subject, founded on any better evidence than conjecture, is that America was peopled by the way of Beering's strait. It is certain that an easy communication has existed between the two continents at this point for several centuries. However, arguing merely from this fact, it is as easy to prove that the old world received its inhabitants from the new, as the contrary. With the exception, perhaps, of the Esquimaux, all the Indians have the same physical characteristics. The bronze or copper colour, the straight, coarse, black hair, the hazel eyes, the high cheek bones and erect form, are common to them all. There is, indeed, some difference in the stature of different tribes. The Osages are very tall, and the Shoshonees are below the middle stature. Each race, and, indeed, each tribe, has its peculiar physiognomy. To a European or Anglo-American, all Indians look alike; but one accustomed to them can distinguish the tribes with almost unerring certainty. Thus a Dahcotah is as readily distinguished from a Chipeway or a Winnebago by his features as his dress. Yet the difference is not so great as to induce a belief that all the tribes are not descended from the same stock. The Esquimaux of Greenland and the eastern part of the continent differ from the red Indians in complexion, stature, and in the position of the eyes, which are set obliquely in their orbits. As we go eastward, along the northern shore of America, we find the Esquimaux as tall as other races of men. After passing the mouth of Mackenzie's river, they are found to blend with the Indians in every particular, so that it is hard to say where the Esquimaux become Indians, or where the Indians become Esquimaux. As low on the coast of the Pacific as Nootka sound, the natives have some characteristics of the Esquimaux race. Whether these people be of the same stock as the Indians or not, it is almost certain they have a common origin with the savages of the northern shores of the old continent. Perhaps the diminutive stature of the eastern Esquimaux is owing to their mode of living, which continually exposes them to every hardship and privation. There is yet another point of difference between this people and other Indians: from cape Farewell to Beering's strait, the Esquimaux speak one language, and derive almost their whole subsistence from the sea; whereas the red Indians never resort to fishing where they can do otherwise, and speak a great variety of dialects, even when the language of the several tribes is radically the same. Considering the Esquimaux as Indians, a brief description of them will not be amiss. The average height of those in Greenland and the eastern part of America is beneath five feet. They are deficient in physical strength, and the muscle of

even the young and strong men is not prominent or well developed. The necks of the men are small and shrivelled; those of the women are well proportioned. Distended abdomen is universal among them, but corpulence is not common. Both sexes dress alike. Their dress consists of a jacket, with a hood, a pair of breeches which reach below the knee, and an enormous pair of boots, all of seal skin. The jacket has one flap before and another behind, both of which hang nearly to the ground. These habiliments, doubled, or even trebled, are their protection in winter and summer. Sometimes these garments are made of other materials. The clothing of the children does not differ from that of adults. Their principal articles of food are train oil and the flesh of seals and walrus. These animals are watched for hours on the ice, and finally despatched with spears. In summer, the Esquimaux kill a few reindeer, and, in districts where they are found, musk oxen. They also attack and destroy the polar bear. Their only arms are spears, and bows and arrows, all or most of which weapons are rudely constructed of pieces of bone and fragments of wood, fastened together and tipped with ivory. As their country produces no wood, they are compelled to resort to such means. In winter, they reside in huts made of snow, which are lighted and warmed by lamps. Their summer habitations are tents of skins, which are supported by the bones of marine animals and reindeer's horns. When they travel in winter, they transport their effects on sledges made of bone, and drawn by dogs. Procuring food is the sole duty of the men, but all other labours devolve on the women. Both sexes are equally expert in the management of canoes, which are made of seal skins, stretched on a frame of wood or bones. One tribe of Esquimaux, discovered by captain Ross in the north-eastern part of Baffin's bay, have no canoes, or any means of floating excepting on pieces of ice. The Esquimaux have the same rambling propensity which distinguishes other Indians, with this difference; they prefer the most desolate and inhospitable regions. They have no settlements or fixed places of habitation, but there are several mustering points, at which they assemble at certain stated times: Igloolik, the mouth of the Coppermine, and the mouth of the Mackenzie, are some of them. There is no marriage ceremony among the Esquimaux. Children are betrothed in infancy. Bigamy is common, but a man seldom has more than one wife at a time. Sometimes they select wives for themselves. Divorces depend on the pleasure of the parties, and are very common. Children are also adopted, and the connexion binds the parties as firmly as the ties of blood. Like other Indians, they are very fond of their children, whom they never chastise or correct. This kindness is not reciprocated by the children, who abandon their parents whenever they become burdensome. The Esquimaux are superstitious, and have priests who pretend to hold intercourse with the invisible world. The gods of their worship are many. Where they have had little or no intercourse with the whites, the Esquimaux are scrupulously honest. They never touch each other's property without permission. Yet they are envious to a degree scarcely credible. The possession of any article draws on a man the ill will of all his neighbours. Gratitude is absolutely unknown to them. In sickness or danger, the husband cares not for the wife, nor the wife for the husband. Parents receive no attention in their old age, and parents deny their children the rites of sepulture. Selfishness is the ruling principle of the Esquimaux. Their hospitality, like that of other savages, is universal. Strangers are received in the kindest manner; every want is removed, every accommodation

supplied. This good quality is balanced by a proneness to falsehood. Their lies are chiefly confined to calumnies against each other, and false accusations. This mostly prevails among the women. They are not quarrelsome nor ferocious, nor are they cowardly. In pain, cold, starvation, disappointment, or when ill treated, their equanimity is admirable. They seldom dispute or quarrel, and revenge is scarcely known among them. Yet they venture to sea on loose cakes of ice, and attack the polar bear without the least hesitation.

The Indians in the northern parts of North America are divided into several great families. The Algonquin or Chippeway race is one of the two most numerous now in existence. All the tribes of New England were Algonquins, if we may take identity of language, manners, and customs, as a proof of the fact. The vocabulary of the Narraganset tongue, recorded by Roger Williams, proves them to have been a branch of the Algonquin stock. The Mohicans, considered the progenitors of the other tribes in New England, spoke the same tongue. The tribes in Maine claimed the same origin. The Delaware, or Lenni Lenape, were of the same family, and their language has been pronounced, by competent judges, the most perfect existing. The Iroquois, or Six Nations, once dreaded from the Atlantic to the Mississippi, are Algonquins. This tribe did not still does extend from the mouth of the St Lawrence to the Mississippi, and thence northward to Great Slave lake; for so far do the Nayheewawk or Katteneaux extend their rambles. On the western side of the Mississippi is another great Indian family, viz., the Sioux or Dahcotah. The Dahcotah proper inhabit the country on the west side of the Mississippi, north of the Wisconsin, to the sources of the Mississippi. Their territory extends westward to the Missouri. This tribe speak a language radically distinct from that of the Algonquin race. Their origin is unknown, and their own traditions are at variance on this point one with another. One account, and the most probable, represents them as having been driven from the confines of Mexico by the Spaniards. The branches of this tribe are the Winnebagoes, the Otoes, the Ioways, the Missourians, the Assiniboinis, the Omahaws, the Kanzas and the Osages. All these tribes speak dialects of the Dahcotah tongue. The Assiniboinis are known also by the names of Ossinneboins, Ossinnepoilles, Stone Indians, and Hohays. This last is the name they give themselves. Their secession from the Dahcotah stock is recent, and its cause is as follows: One Dahcotah had eloped with the wife of another, and taken refuge in the tents of his kindred. The husband, going to reclaim his spouse, was slain by the adulterer. His father and uncles, demanding blood for blood, according to the laws of the tribe, were slain also. The quarrel of the dead was taken up by their relatives, and the kindred of the guilty persons were defeated with loss. A series of bloody encounters ensued, till at last the party of the original aggressors were worsted and separated from the tribe. They were called Hohays, and have been at war with the Dahcotahs till within a few years. They now roam over the plains, from the Saskashawin to the Missouri, where they live by hunting the buffalo. The principal resort is about Devil lake. As well as the Indians farther north-west, they have few guns, and other articles, the manufacture of the whites. The number cannot be ascertained, but it is certain they exceed a thousand fighting men. A tradition of the Winnebagoes says they were driven from the front of Mexico by the Spaniards, towards whom they entertain a hereditary hatred to this day. Within centuries, they were united with the Otoes, Ioways,

and Missouries. They are a fierce, warlike people, and have more national spirit than any other Indians on the frontier. The Otoes and Missouries, now united, are renowned among the tribes of the Missouries for their bravery. They can muster about 300 men. The Ioways still dwell on the Mississippi. They have from 100 to 200 men. The Osages are divided into three tribes, and can boast over 1000 warriors. The Kansas inhabit the plains about the heads of the Arkansas and Red rivers. Their number is unknown. The Omahaws live high up the Missouri. Besides these tribes, there dwell on the Mississippi, between the river Des Moines, the Wisconsin, and the Missouri, the Sacs and Foxes, a branch of the Chippeway tribe. They speak the Chippeway tongue, and number above 1000 men. On the Missouri are the Pawnees, divided into three tribes, of which the Arikarees are a branch. They live by hunting the buffalo, and are said to have a language of their own. The Mintarees or Bigbellies, the Mandans, the Crows, and the Blackfeet, also live on the Missouri, and each is said to have a language of its own. Their numbers are unknown. The Shoshonees live between the head waters of the Missouri and Columbia rivers. They are almost constantly on horseback, and are at war with the lower tribes of the Missouri. On the Columbia river are the Chobmanish, the Skilloots, Echeloots, Multnomahs, Clatsops, and other tribes. Their haunts and numbers are unknown. They live by fishing as well as hunting, and differ in manners and customs from the tribes east of the Rocky mountains. They are neither so well fed or clad. Most of these tribes have the practice of flattening the heads of infants between boards, whence the general name of Flatheads. They have some commerce with ships on the north-west coast. Nothing is known of the languages of any of these people. In the south of the United States, there are four tribes, viz., the Chickasaws, Choctaws, Cherokees, and Creeks. All these have made some progress in civilisation. The Cherokees have a written and printed language, said to be radically different from all others. They number about 15,000 souls. (See *Tuttlakes*.) The Choctaws and Chickasaws are more numerous. North of Great Slave lake is another family of Indians, among which are the Chippewyans, the Copper Indians, the Dog Ribs, and the Hare Indians. (The subjoined cut represents the usual costume of these tribes.) The three first speak the same language. They all wage war with the Esquimaux. The Dog Ribs are also oppressed and persecuted by the Copper Indians, who rob them, and take from them their women, whenever an opportunity occurs. These tribes live by hunting the reindeer, chiefly, and by fishing in the winter. Their morals and manners are below the standard of their southern neighbours, and their number is very small. There are also the remnants of some tribes residing within the limits of

the United States, viz., the Mohegans, the Delawares, the Shawanoes, the Senecas, the Oneidas, the Pankashaws, and some others. Most of these live by agriculture, as well as the chase. Intercourse with the whites has not been advantageous to them. They have learned all the vices of the civilized state without its virtues. Besides all these, there is a tribe in the interior of Newfound-

land, who have shunned all intercourse with the whites. The Indians have uniformly resisted all attempts to civilize them where they could support themselves by the chase. Some few tribes, such as the Southern Indians and the remnants of the Six Nations, having been hemmed in by the whites, and circumscribed in their limits, so as to be unable to live by hunting, have turned to agriculture for subsistence. But such a departure from the habits of savage life is not to be found where there has been a possibility of supporting life by other means. The hospitality of Indians is among their most striking qualities. In any of the tribes, a stranger is received with the utmost respect and attention. On his arrival, he is served with the best in the wigwam, seated on the best seat, and treated with the utmost respect and attention. His person and property are considered sacred. He may remain as long as he pleases in a wigwam, without any questions being asked, and retire unopposed. Feasts are made for him, and, though his appetite may be satisfied, to refuse any thing set before him gives great offence. With all, or almost all, the Indian tribes, the sole care of the men is to provide food. The labour is the exclusive lot of the women. The use of the axe or hoe is considered beneath the dignity of the male sex. It belongs to the females to plant corn, to make and mend garments and mocassins, to build, to pitch tents, cut wood, bring water, to tend horses and dogs, and, on a march, to carry the baggage. The women do not murmur at this, but consider it a natural and equitable distribution of family cares. But they are regarded as an inferior race, and often transferred as property. Polygamy is general. Every man has as many wives as he can support, and, in marriages, the will of the bride is seldom or never consulted. A man addresses himself, indirectly to the parents of his intended wife, and her fate depends on their will. The custom of dowry is reversed among Indians. The man makes certain presents to the parents of his wife, instead of receiving a portion with her. The marriage ceremony is always very simple, and, in most tribes there is none at all. Adultery is punished by cutting off the nose, or otherwise mutilating the offending female; sometimes, though rarely, with death. In some tribes, this crime is regarded as a venial fault, and, in very many, the husband lends his wife to a friend without opposition on her part. Divorces are frequent, and at the pleasure of the contracting parties. In such cases, the wife is usually left to provide for the children as she may. It is no uncommon thing to see an Indian woman who has been five or six times repudiated before she finally settles in life. In some tribes, especially those of Dahcotah origin, it is held the duty of each man to marry all the sisters of a family, and to have as many wives as he can support. In most tribes, and we believe in all, incest is held in abhorrence. Instances of devoted attachment are not uncommon. All Indians of whom we have any knowledge, believe in one Supreme God and the immortality of the soul. They attribute all good and all power to the Supreme Being. Many tribes also believe in the existence of an intelligent evil principle, whose ill offices they endeavour to avert by prayer and sacrifice. They never ask the Supreme for any thing, but merely return thanks for benefits received, saying that he is the best judge of what is for their advantage. They believe in many subordinate deities, two of whom reside in the sun and moon. They attribute supernatural powers to all serpents, especially rattlesnakes, and will kill no animal of the genus. Even the eel escapes on account of his resemblance. They pay religious honours to rocks and venerable objects. They believe that brutes have immortal souls as well

as men, and, in short, that all animated nature teems with spirits. In their belief, sorcery is blended with the healing art, and their priests are also physicians and jugglers. These priests practise feats of sleight of hand with all their religious ceremonies; but, with a few exceptions, they have no power or influence over the multitude. The future state of the Indians is a material paradise, where they will follow the same occupations, and enjoy the same delights, they have experienced in this world. They have also a vague idea of future punishment for sins committed in the body. Among the superstitions of the Algonquin and Dahcotah tribes, is a very singular one: A man is sometimes devoted, by his parents or himself, to a life of ignominy. In this case, he dresses like a woman, and performs all female avocations. He associates with women only, and sometimes takes a husband. He is held in utter contempt by all, though his condition be not of his own choice. This condition is frequently owing to a dream of his parents, while he is yet unborn. In many tribes, men have what they call their *medicine bags*. These are filled with bones, feathers, and other rubbish. To the preservation of their medicine bags they attach much importance. Besides this, each holds some particular animal in reverence, which he calls his *medicine*, and can by no means be induced to kill, or eat when killed, for fear of some terrible misfortune. Moreover, the Indians leave tobacco, worn out clothing, and other articles, on rocks, as sacrifices to invisible spirits. The above is nearly the sum of their religion. It is, we believe, impossible to estimate the number of the North American Indians with any degree of accuracy. It is, however, very small throughout, in proportion to the extent of territory; for a hunting people cannot be very numerous. Their wars, of which we have heard so much, do not materially affect them. They are carried on in detail, by small parties, and, consequently, are not very destructive. They very seldom give quarter, but when a prisoner is spared, he is sure of being adopted by the conquering tribe. The tribes who inhabit the prairies go to war on horseback, and their weapons are spears and bows and arrows. Those who inhabit the forests are generally armed with guns. Their courage is moral and passive rather than active. They think it cowardice to be affected by calamity, or to give way to passion or feeling. To be always ready and willing to die, and to suffer whatever may befall with constancy, is their idea of the perfection of courage. As to government among them, there is none. They have no laws; but there are customs, which every individual scrupulously observes. In cases of murder, for instance, the rule is, blood for blood, and the homicide rarely shuns the penalty of his deed. They have chiefs, but the power of these is limited to persuasion, and they can command no one. Sometimes a chief becomes such in virtue of his achievements in war, or his wisdom. In some tribes, there is something like hereditary rank; but even then, authority does not descend in a direct line. The son of a chief is often set aside, to make room for one more worthy. But in war, implicit obedience is given to the commands of the leader. The tribes that inhabit the prairies all live by hunting the buffalo, mostly on horseback. Those who dwell in wooded countries hunt deer and smaller animals. The more primitive savages are the poorest, but at the same time the least dependent, for they have few wants, and can supply those few without assistance. Those who live nearer the whites have more of the comforts of life, but are no whit more civilized or happier, for their enjoyments are not multiplied. We may say that, if the Indian trade of the Mississippi were interrupted for five years, all the aborigines of that

quarter would be in danger of perishing, as they depend on the whites for clothing and weapons. The Indians can never be dangerous, as there is no union among them. They have no letters, unless we count a few rude hieroglyphics as such. On the whole, we may speak of them as a brave, reckless, generous, and unfortunate people. The Indians in the southern part of North America have been subject to the Spaniards, and are now dependent on the republics of Mexico and Guatemala, if we except some tribes, such as the Apaches, the Nabajons, and the Mosquitos. The independent tribes of the north of Mexico resemble those of the United States in manners and customs. Living by the chase and plunder, and provided with fleet horses, they harass the frontiers and hunters. On the coasts of Yucatan, the Indians live by hunting, fishing, and the trade in dye-wood. The extensive ruins of cities in Mexico prove the former extent of its population. The natives possess great muscular force, are well formed, and live to a great age. It is difficult to form an opinion of the character of a people which has been so long subjected to the most cruel oppression. At the time of the conquest, the rich inhabitants of Mexico fell a prey to the rapacity of the Spaniards, and the Aztec priests, who were the depositaries of all the historical knowledge of the country, became the victims of fanaticism. The Mexican Indians are grave, melancholy, and silent; their music and dances display the same character. The Indians of South America do not differ materially, in their physical characteristics, from those of the northern half of the continent, and, except those of Peru and Chile, are without civilisation. In the extensive regions formerly belonging to Spain, they may be divided into two classes,—the independent Indians, or *Indios bravos*, and those who have been reduced to subjection. The former are entirely strangers to agriculture; support themselves by the chase, and fishing; some of them eat ants, lizards, and even a kind of mud. The natives of Peru, descendants of the ancient inhabitants of the empire of the Incas, have, as well as those of Colombia, been emancipated, since those countries have delivered themselves from the Spanish yoke. Their services were important during the war of the colonies against the mother country. They are, in general, well made and healthy. They are superstitious, wearing amulets on different parts of their bodies. They make bitter, intoxicating drink from a certain plant, and use poisoned arrows. Their villages are fortified, and, in case of necessity, they retire into the mountains. The Indians of Chile are mostly independent. Their features are regular, and their complexion is not very dark. Their principal wealth consists in herds of oxen, horses, and guanacos. They pay little attention to agriculture, being nomadic in their habits. They worship the stars, and recognize a Great First Cause. Astronomy is not unknown to them. (See *Americanism*.) In Buenos Ayres, the missions of the Jesuits succeeded in some degree, in civilizing the natives. The tribes of Brazil are numerous; many of them are entirely savage, and both sexes go naked. Their manners and habits are very similar to those of the North American tribes. They live by the chase, which, with war, is the only occupation of the men; the women are the labourers, beasts of burden, servants, &c., of these warlike tribes. Their mutual wars are very sanguinary, and many of them are constantly at war with the Portuguese, while others have entered into friendly connexions with them. Some of them have adopted fixed habitations, and practice a rude kind of agriculture; some of them make vases of clay, gather cotton, and make cloth. At the southern extremity of South America are the Pat-

gians (q. v.), who have large, nervous frames, a dark complexion, a flat nose, high cheek bones, and a large mouth. The stories of their gigantic size have not been confirmed by the later voyagers. (See *Patagonians*.) The principal tribes of South America are the Galibis, Maynas, Omaguas, Maypans, Yaruros, Guajiros, Guajaribes, Carabais, Macas, Otomacs, Quixos, Tamanacs, Chunchos, Piros, Chirenes, Moxos, Chiquitos, Abiponians, Guaranis, Puelches, Guicouros, Araucanians, Toupis, Toupitambas, Marjats, Puris, Patagonians, &c.

LANGUAGES OF AMERICAN INDIANS.\* The aboriginal languages of the continent of America exhibit various phenomena, a knowledge of which will be found indispensable to a just theory of speech. It is true, that we have long had our systems of universal grammar, or, in other words, our theories of language, as deduced from the small number of European and Asiatic tongues, which have been hitherto studied by the learned; but from the rapid advances made, during our own age, in comparative philology, particularly by means of the unwritten dialects of barbarous nations, there is reason to believe that some important modifications are yet to be made in our theories. Of the various unwritten languages, those of the American continent present us with many new and striking facts. We are informed by Mr Du Ponceau, from whose writings we derive nearly all that is known of the general characteristics of these dialects, that there appears to be "a wonderful organization, which distinguishes the languages of the aborigines of this country from all the other idioms of the known world."<sup>†</sup> That eminent philologist was the first to discover, and make known to the world, the remarkable character, which pervades, as far as yet known, the aboriginal languages of America, from Greenland to Cape Horn. In the period which has elapsed since the publication of his Report, by the American Philosophical Society at Philadelphia, in 1819, all the observations which have been made on Indian languages, at that time unknown, have confirmed his theory; or, as he expresses it, his general result of a multitude of facts collected with care. This result has shown, that the astonishing variety of forms of human speech, which exists in the Eastern hemisphere, is not to be found in the Western. There we find no monosyllabic language, like the Chinese and its cognate idioms; no analytical language, like those of the North of Europe, with their numerous expletive and auxiliary monosyllables; no such contrast is exhibited as that which is so striking to the most superficial observer, between the complication of the forms of the Basque language and the comparative simplicity of its neighbours, the French and Spanish; but a uniform system, with such differences only as constitute varieties in natural objects, seems to pervade them all; and this genus of human languages has been called (by Mr Du Ponceau) *polysynthetic*, from the numerous combinations of ideas which it presents in the form of words. It is also a fact, says the same learned writer, that the American languages are rich in words, and regular in their forms, and that they do not yield, in those respects, to any other idiom. These facts have attracted the attention of the learned in Europe as well as in that country; but they have not been able entirely to remove the prejudices that have been so long enter-

tained against the languages of savage nations. The pride of civilization is reluctant to admit facts like these, because they show how little philosophy and science have to do with the formation of language. A vague idea still prevails, that the idioms of barbarous tribes must be greatly inferior to those of civilized nations, and reasons are industriously sought for, not only to prove that inferiority in point of cultivation, which would readily be admitted, but also to show that their organization is comparatively imperfect. Thus a learned member of the Berlin academy of sciences—baron William von Humboldt—in an ingenious and profound Dissertation on the Forms of Languages (*Ueber das Entstehen der grammatischen Formen und ihren Einfluss auf die Ideen-Entwicklung*, Berlin, 1822), while he admits that those of the American Indians are rich, methodical, and artificial in their structure, yet would not allow them to possess what he there called genuine grammatical forms (*ächte formen*), because, says he, their words are not inflected, like those of the Greek, Latin, and Sanscrit, but are formed by a different process, which he calls *agglutination*; and, on that supposition, he assigned to them an inferior rank in the scale of languages, considered in the point of view of their capacity to aid the development of ideas. We have understood, however, that this very learned writer has, upon further examination, yielded, in a great degree, if not entirely, to the opinions of Mr Du Ponceau. He certainly must have found, in the Delaware Grammar of Mr Zeisberger, since translated and published by the Philosophical Society, under the editorial care of Mr Du Ponceau, those inflected forms which he justly admires, and that the process, which he is pleased to call *agglutination*, is not the only one which our Indians employ in the combination of their ideas and the formation of their words. This peculiar process of compounding words, as Mr Du Ponceau observes, in his preface to Zeisberger's Delaware Grammar, is undoubtedly the most curious thing to be found in the Indian languages. It was first observed by Egedé, in his account of Greenland; and Mr Heckewelder explains it at large, in the eighteenth letter of his Correspondence with Mr Du Ponceau (*Transactions of the Historical and Literary Committee of the American Philosophical Society*). By this means, says governor Colden, speaking of the Iroquois, these nations can increase the number of their words to any extent. None of the languages of the old world, that we know of, appear to possess this prerogative; a multitude of ideas are combined together by a process, which may be termed *agglutination*, if the term be found agreeable, but which, whatever name it may receive, is not the less a subject of real wonder to the inquiring philologist. One example, from the Delaware language, will convey a clear idea of this process of compounding: "and I have chosen," says Mr Du Ponceau, "this word for the sake of its euphony, to which even the most delicate Italian ear will not object. When a Delaware woman is playing with a little dog or cat, or some other young animal, she will often say to it, *Kuligatchis*, which I would translate into English—*Give me your pretty little paw*, or, *What a pretty little paw you have!* This word is compounded thus: *k* is the inseparable pronoun of the second person, and may be rendered *thou* or *thy*, according to the context; *uli* (pronounced *oollee*) is part of the word *wulit*, which signifies *handsome* or *pretty*; it has also other meanings, which need not be here specified; *gat* is part of the word *wichgat*, which signifies a *leg*, or *paw*; *schis* (pronounced *sheese*) is a diminutive termination, and conveys the idea of *littleness*: thus, in one word, the Indian woman says, *thy pretty little paw!* and, according to the gesture

\* The subject of this article is so interesting, in regard to general and comparative philology, and so little is generally known respecting it, that it has been thought proper to allow it a space more than proportionate to the usual length of philological articles in this work.

† Report of the historical and literary committee to the American Philosophical Society at Philadelphia, drawn up by Mr Du Ponceau, 1819.

which she makes, either calls upon it to present its foot, or simply expresses her fondling admiration. In the same manner, *pildpe* (a youth) is formed from *pilsit* (chaste, innocent,) and *lendpe* (a man). It is difficult to find a more elegant combination of ideas, in a single word, of any existing idiom. I do not know of any language, out of this part of the world, in which words are compounded in this manner. The process consists in putting together portions of different words, so as to awaken, at the same time, in the mind of the hearer, the various ideas which they separately express. But this is not the only manner in which the American Indians combine their ideas into words. They have also many of the forms of the languages which we so much admire—the Latin, Greek, Sanscrit, Slavonic, &c.—mixed with others peculiarly their own. Indeed, the multitude of ideas, which in their languages are combined with their verbs, has justly attracted the attention of the learned in all parts of the world. It is not their transitive conjugations, expressing, at the same time, the idea of the person acting and that acted upon, that have excited so much astonishment. These are found also, though not with the same rich variety of forms, in the Hebrew and other Oriental languages. But, when two verbs, with intermediate ideas, are combined together into one, as in the Delaware *n'achingiwipoma* (I do not like to eat with him), which the abbé Molina also declares to exist in the idiom of Chile—*iduancloclavin* (I do not wish to eat with him)—there is sufficient cause to wonder, particularly when we compare the complication of these languages with the simplicity of the Chinese and its kindred dialects in the ancient world. Whence can have arisen such a marked diversity in the forms of human speech? Nor is it only with the verbs that accessory ideas are so curiously combined in the Indian languages; it is so likewise with the other parts of speech. Take the adverb, for instance. The abstract idea of time is frequently annexed to it. Thus, if the Delawares mean to say—if you do not return—they will express it by *matlatsch gluppiquee*, which may be thus constructed: *matla* is the negative adverb *no*; *tach* (or *tah*) is the sign of the future, with which the adverb is inflected; *gluppiquee* is the second person plural, present tense, subjunctive mood, of the verb *gluppicchten*, to turn about, or return. In this manner, every idea meant to be conveyed by this sentence, is clearly understood. The subjunctive mood shows the uncertainty of the action; and the sign of the future tense, coupled with the adverb, points to a time not yet come, when it may or may not take place. The Latin phrase *nisi veneris* expresses all these meanings; but the English *if you do not come*, and the French *si vous ne venez pas*, have by no means the same elegant precision. The idea which, in Delaware and Latin, the subjunctive form directly conveys, is left to be gathered in the English and French, from the words *if* and *si*, and there is nothing else to point out the futurity of the action. And, where the two former languages express every thing with two words, each of the latter requires five, which yet represent a smaller number of ideas." Mr Du Ponceau, then, justly asks, to which of all these grammatical forms is the epithet *barbarous* to be applied? This very cursory view of the general structure of the Indian languages, exemplified by the Delaware, will at least convince us, that a considerable degree of art and method has presided over their formation.

Mr Du Ponceau has summed up the general results of his laborious and extensive investigations of the American languages, including the whole continent, from Greenland to cape Horn, in three propositions—

"1. that the American languages in general are rich in words and in grammatical forms, and that, in their

complicated construction, the greatest order, method, and regularity prevail; 2. that these complicated forms, which I call *polysynthetic*, appear to exist in all those languages, from Greenland to cape Horn; 3. that these forms appear to differ essentially from those of the ancient and modern languages of the old hemisphere." In North America, he selected for investigation the three principal mother tongues, namely, the Karalit (or language of Greenland and the Esquimaux), the Delaware, and the Iroquois; in Middle America, the Poconchi (spoken in Guatemala), the Mexican proper, and the Tarascan dialect; in South America, the Caribbee and Araucanian languages. For the purpose of obtaining general results like those above stated, it was not necessary or useful, in the first instance, to go into minute details, nor to confound the reader by an extensive display of numerous idioms; but to take the widest possible range, so as to adduce examples from quarters the most remote from each other. In this manner, we can take a commanding position, assume our general rule, and call for exceptions. These and other results, when first announced, appeared so extraordinary in the languages of "savages," that superficial theorists, who relied upon their own visionary speculations, and mere practical men, who trusted implicitly to the loose information of illiterate Indian interpreters, boldly and arrogantly called in question the correctness of them. The learned author and his venerable friend, the reverend Mr Heckewelder, who first drew the public attention to this subject, were most unceremoniously treated, the former as an enthusiast, whose feelings had outrun his judgment, and the latter, as at best an innocent ignoramus, and very near, if not quite, a downright impostor, in regard to a language which he had studied forty years. Mr Du Ponceau repelled the unworthy insinuations by an appeal to facts, with a forbearance and dignity, and, we may add, a knowledge of his subject, which must have been felt by his adversaries as the severest of reproofs. The learned author, denying that he was an enthusiastic or exclusive admirer of the Indian languages, founded his arguments, in reply, upon incontrovertible facts, stated by missionaries and other writers of our own time; but, if he had thought it worth the pains, he was well aware, that proofs of the same kind might have been found in very ancient writers, whom even his adversaries would not have suspected of enthusiasm in philology; and these proofs ought to have been well known to these adversaries, and ought, in candid minds, to have repressed the unhesitated insinuations to which we allude. We shall give an example or two from the earlier writers.

The extraordinary capacity of compounding words, which is so remarkable in the Indian languages, was remarked upon so long ago as the time of the celebrated New England missionary, called *apostle Eliot*: who, in his *Grammar of the Massachusetts Indian Language* (first published at Cambridge, New England, in 1666, and republished at Boston, in 1822), thus speaks of it: "This language doth greatly delight in compounding of words for abbreviation, to speak much in few words, though they be sometimes long, which is chiefly caused by the many syllables which the grammar rule requires, and suppletive syllables, which are of no signification, and curious care of euphonic." Again; speaking of that very remarkable feature of these languages, the want of the verb *to be*, Eliot says: "We have no complete distinct word for the verb substantive, as the learned languages and our English tongue have, but it is made a regular composition, whereby many words are made verb substantive;" of which he gives an example corresponding to the modes of formation existing in

these languages at the present day: "The first sort of verb substantives is made by adding any of these terminations to the word—*yeuoo, aoo, ooo* (i. e., *yeuoo, a oo, o oo*)—with due euphonia; and this is so, be the word a noun, as *wosketomp-o oo* (he is a man), or adverb, as *wompigeeu-oo* (it is white), or be the word an adverb, or the like."

As to the copiousness of these languages, Mr Du Ponceau observes, that it has been said, and will be said again, "that savages, having but few ideas, can want but few words, and therefore that their languages must necessarily be poor;" to which opinion he replies by this appeal: "Whether savages have or have not many ideas, it is not my province to determine: all I can say is, that, if it is true, that their ideas are few, it is not less certain that they have many words to express them. I might even say, that they have an innumerable quantity of words; for, as Colden justly observes, they have the power of compounding them without end." As a further proof, he adds the fact, that Mr Zeisberger's dictionary of one of the Iroquois languages—the *(Onondago* (in German and Indian)—consists of seven quarto manuscript volumes, equal to 1775 full pages of writing, consisting of German words and phrases, with their translation into Indian; upon which he justly remarks, "that there are not many dictionaries of this size; and, if this is filled, as there is no reason to doubt, with genuine Iroquois, it is in vain to speak of the poverty of that language."

We add one more testimony of an ancient date, respecting the North American dialects. It is that of the celebrated Roger Williams, who was distinguished for his knowledge of the Indian languages. So long ago as 1648, he published his valuable little work (reprinted by the Rhode Island Historical Society, 1827), called "A Key into the Language of America;" that is, of New England; and, in describing his work, he says, "The English for every Indian word or phrase stands in a straight line directly against the Indian; yet sometimes there are two words for the same thing, for their language is exceeding copious, and they have five or six words sometimes for one thing." The same copiousness is found to exist in the languages of Middle America, as was made known to the European world, long ago, by Clavigero, in his History of Mexico; and also in the languages of the southern part of our continent, as will be found in the valuable History of Chile, by the abbé Molina. We must content ourselves with barely referring to these works on the present occasion, as our principal object is the languages of North America; but in regard to those of Middle and South America, the reader will find, in the works here cited, and in some others, a thorough refutation of the strange opinions of speculative writers, who have presumptuously passed judgment upon a subject, before they had the means of becoming acquainted with it, and decried what they could not comprehend.

We are not yet possessed of sufficient data for determining how many principal stocks, or families of languages, there are in North America. Mr Jefferson, in his Notes on Virginia, upon information which is admitted to be very imperfect, has hazarded an opinion, that they are very numerous; and then he proceeds, from this assumed state of facts, to draw an inference in contradiction of the received opinion of the Christian world as to the age of the earth. His reasoning, which has been too hastily adopted into some popular works in general use, is as follows: "But, imperfect as is our knowledge of the tongues spoken in America, it suffices to discover the following remarkable fact. Arranging them under the radical ones to which they may be palpably traced,

and doing the same by those of the red men of Asia, there will be found, probably, twenty in America for one in Asia of those radical languages, so called; because, if they were ever the same, they have lost all resemblance to one another. A separation into dialects may be the work of a few ages only; but for two dialects to recede from one another till they have lost all vestiges of their common origin, must require an immense course of time, perhaps not less than many people give to the age of the earth. A greater number of those radical changes of language having taken place among the red men of America, proves them of greater antiquity than those of Asia." This celebrated writer, however, was in a great error as to what he assumes to be a "remarkable fact." The "radical" languages of this continent, instead of being so numerous as he supposes, will be found, so far as we may judge from the actual, not assumed, facts of which we are now possessed, to be very few in number. The various dialects of North America, for example, eastward of the course of the river Mississippi, appear to be all reducible to three, or, at most, four principal stocks, namely—1. the Karalit, or language of Greenland and the Esquimaux; 2. the Iroquois; 3. the Lenape, or Delaware; and 4. the Floridian stock. With the Esquimaux begin those comprehensive grammatical forms, which characterize the American languages, and form a striking contrast with those of the opposite European shores, in Iceland, Denmark, Sweden, and other countries, indicating strongly, that the population of America did not originally proceed from that part of the old continent. The Iroquois dialects are spoken by the Six Nations, the Wyandots or Hurons, and other tribes towards the north. The Lenape, or Delaware stock, is the most widely extended of any of the languages spoken eastward of the Mississippi. It is found in different dialects, through the extensive regions of Canada, from the coast of Labrador to the mouth of Albany river, which falls into Hudson's bay, and from thence to the Lake of the Woods; and it appears to be the language of all the people of that country, except the Iroquois, who are by far the least numerous. Out of Canada, few of the Iroquois are found. All the rest of the Indians, who now inhabit this country, to the Mississippi, speak dialects of the Lenape stock. When the Europeans arrived here, these Indians were in possession of all the sea coast from Nova Scotia to Virginia. Hence, as we are told, they were called *Wapanachki*, or *Abenakis* (men of the East), and, by La Hontan, and some other writers, *Algonkins*. In the interior of this range of the sea coast, also, we find dialects of the Lenape. The Floridian stock, as its name indicates, comprehends the languages spoken on the southern frontier of the United States.

Of all these languages, the Delaware, in the north and the Cherokee, in the south (the latter being at present classed under the Floridian stock), are the best known to us—the former, by means of Mr Du Ponceau's correspondence with Mr Heckewelder, and by his edition of Mr Zeisberger's Delaware Grammar; and the latter, by means of the missionary establishment in the Cherokee country, as well as from the newspaper printed by the natives themselves, who have made greater advances in civilization than any other Indian nation of the north. We shall accordingly illustrate the general subject of this article by examples from these languages, which, being of two entirely different stocks, will give as much information on this subject as the general reader will desire, and as will be consistent with the plan of our work. We shall follow the order of our own grammars.

1. The *Article*. In Eliot's ancient Grammar of the Massachusetts' dialect, and in Zeisberger's Gram-

mar of the Delaware, before cited, no mention is made of the article as a part of speech; but Mr Du Ponceau's investigations led him to the conclusion that they possessed one, as he particularly stated, in his notes on the new edition of Eliot's Grammar; and this was confirmed by Mr Heckewelder, whose letter on the subject is there published. The article, which is *mo*, or *m'*, is used for the English *a* and *the*; but it is not frequently employed, because the words are sufficiently understood without it. In the Cherokee, we do not find that any distinct word is used for our *a* and *the*; but, where required, they use a word equivalent to the numeral *one*, and the demonstrative pronouns *this*, *that*, agreeably to the original use and nature of the words which we now call *articles*.

2. *Nouns*.—(a) *Cases*. The Indians have no declensions, generally speaking; that is, the nouns are not declined by inflections, as in Latin and Greek. In the Delaware, however, according to Mr Zeisberger, in two cases, the vocative and ablative (which last Mr Du Ponceau calls the *local case*), there is an inflection. The nominative case is simply the name of the thing, as in English; *lenno* (man), *sipu* (river).<sup>\*</sup> The genitive is expressed by placing the noun so employed immediately before that which is used in the nominative, and sometimes by prefixing the inseparable pronoun of the third person, *w*; as we say in English, *John his book* (to be explained under the head of *Pronouns*), for *John's book*; *Getannitowit quisall* (God's son); *Nihillalquonk wtanglowagan* (the Lord's death), in which last example, *anglowagan* signifies *death*, *w* is the inseparable pronoun *his*, and the *t* is inserted for the sake of euphony. The dative case is expressed by inflections in the verbs, and by prefixes and suffixes, as will be explained hereafter; as, *nemilan* (I give [to] him); *milup* (he gave [to] him); *ndellup* (I said [to] him). The accusative is likewise expressed in a similar manner; *n'dahoala* (I love him); *Getannitowit n'quitayala* (I fear God; literally, God I fear him). The vocative is expressed (in the Delaware) by the termination *an*, and by *enk*, when coupled with the pronoun *our*; as *Nihillalan* (O Lord); *wetochemelenk* (O, our father);—the ablative or local case, by the suffixes *ink* and *unk*, and expresses *in*, *in the*, *on*, *out of*; as *utenink n'da* (I am going to, or into, town); *utenink noom* (I am coming from, or out of, town); *wuchtschunk noom* (I come from the hill); *ochunk* (at his father's).—(b) *Numbers*. The singular, in general, has no particular inflections to distinguish it from the plural, except in the third person, where it ends in *l*, but most commonly in *wall* (in the Delaware). The plural is variously inflected; there is a singular number combined with the plural, as in *our father*, *my fathers*, and also a double plural, as in *our fathers*. Substantives are generally combined with the inseparable possessive pronoun, which, in the singular, is *n* for the first person, *k* for the second, and *w* or *o* for the third. Example: singular, *nooch* (my father); singular with plural, *noochena* (our father); double plural, *noochenana* (our fathers). The duplication of a syllable, as *nana* in the first person, *waawa* in the second, and *wawawall* in the third, indicates the double plural. So in the second person, *kooch* (thy father); *koochuwa* (your father); *koochuwawa* (your fathers), &c. In speaking of deceased persons, the plural form *naninga* is used, as *nochena* (our father); *nochenanina* (our deceased fathers). But the subject of the numbers of nouns requires a further remark to explain a striking feature in these languages. Some of them, as the Guaranes, in South America,

have only a singular number, and are destitute of a distinct form for the plural, to express which they use either the word *heta* (many), or the numerals themselves. On the other hand, some, as, for example, the Cherokee, have not only the singular and plural, but a dual also, like the Greek and other languages of the Eastern continent; while a third class, as the one last mentioned, have not only the singular, dual, and common unlimited, or indefinite plural of the European languages, but also an additional plural, which some writers have denominated the *exclusive plural*, some the *particular*, and some the *limited plural*. We shall illustrate this by some examples. In the Delaware language, our plural *we* is expressed by *niluna* and *kiluna*; and, in verbs, the initial letters *n* or *k* prefixed denotes them respectively; as, *k'pendameneen* means, generally, *we have heard*, or *we all have heard*, without intending to allude to a particular number of persons; but *n'pendameneen* (the *n* from *n-iluna*) means *we*, in particular (we who constitute our family, nation, select company, &c.); but when no discrimination is intended, the form *kiluna*, or its abbreviation *k'*, is used; as *k'iluna e-lenape-wa* (we the Indians), meaning *all Indians*. We shall have occasion to recur to this subject in our remarks on the verbs.—(c) *Gender*. There are no inflections to denote the masculine, feminine, or neuter genders: but by a very curious and abstract classification, nouns are ranked under two very general classes, *animate* and *inanimate*. To the former belong animals, trees, and all plants of a large growth, while annual plants and grasses belong to the latter class. The masculine and feminine, when it becomes necessary, are distinguished, generally, by words equivalent to *male* and *female*, or *he* and *she*, in English.—(d) *Diminutives*. In the Delaware, these are formed by the suffix *tit* in the class of animate nouns, but by *es* in the inanimate: *lenno* (a man), *lennotit* (a small man); *wikwam* (a house), *wikwames* (a small house); and, in speaking of a pretty little animal, the termination *is* or *this* is used; *mamalis* (a fawn, or little deer); *kuligatahis* (thy pretty little paw), which last example we have before employed to illustrate the mode of compounding words.

3. *Adjectives*. There are not many of these; for those words which, in English, are adjectives, are, in these languages, verbs; and, although not inflected through all the persons, yet they have tenses; and *c* is, doubtless, in this qualified sense that doctor Edwards is to be understood, when he says, of one of the Delaware dialects, "The Mobegans have no adjectives in all their language, unless we reckon numerals, and such words as *all*, *many*, &c., adjectives." We have noticed this remark of Edwards, because it has often been quoted in European publications, and erroneous inferences have been drawn from it respecting the philosophy of language. The same remarks may be applied to the Cherokee language. Degrees of comparison are generally, but not universally, expressed by some word equivalent to *more* or *most*. Numerals may also be classed among adjectives. Few Indians are accustomed to calculate to any great extent; but their languages afford the means of so doing, as well as ours, and since the intercourse of Europeans with them, they have got more into the habit.

4. *Pronouns*.—(a) *Personal Pronouns* are *Separable* or *Inseparable*, but are more frequently used as the latter form, examples of which are above given, under the head of the *Nouns*. When two pronouns are employed in verbs, the last, or the pronoun governed, is expressed (in Delaware) by an inflection, as will be seen under the head of *Conjugation of the Verbs*. The personal pronoun, moreover,

<sup>\*</sup> The reader will, in all these examples, give the vowels the foreign sounds; thus *lenno* is to be pronounced *lenner*; *sipu*, *serpoo*, &c. The *ch* is guttural as in German.

combines itself with other parts of speech, as, with the conjunction *also*; *nepe* (I also); *kepe* (thou also), &c. One further peculiarity in the separable pronouns deserves notice. In conformity, as it should seem, with the general classification of Indian words into *animate* and *inanimate*, the personal pronoun has only two *modes*, as they may be called, the one applicable to the animate, and the other to the inanimate class; thus the separable pronoun of the third person, *nekama*, answers both to *he* and *she* in English. If we wish to distinguish between the sexes, we must add to it the word *man* or *woman*; thus, in Delaware, *nekama lenno* means *he, or this man*, and *nekama ochques* means *she, or this woman*.—(b) *Demonstrative and Relative Pronouns*. The modes of expressing these by various forms and combinations are numerous. Doctor Edwards, it is true, says the Mohegan dialect has no relative corresponding to our *who* and *which*; but Eliot, in the Massachusetts language, and Zeisberger, in the Delaware, give this relative as a distinct, independent part of speech.

3. *Verbs*. The Indian languages exhibit almost an endless variety in their verbs. Every part of speech may be compounded with the verb in various ways. Its fundamental idea, as Mr Du Ponceau observes, in his notes to Eliot's Grammar, is that of existence, *I am, sum*. This abstract sentiment receives shape and body from its combination with the various modifications of being, by action, passion, and situation, or manner of existing; *I am loving, loved, sleeping, awake, sorry, sick*, which the Latin tongue more synthetically expresses by one word, *amo, amor, dormio, vigilo, contristor, aegroto*. Next come the accessory circumstances of person, number, time, and the relations of its periods to each other; *I am, we are, I was, I shall be, I had been, I shall have been*. Here the Latin again combines these various ideas in one word with the former ones; *sum, es, sumus, eram, ero, fueram, fuero*. Sometimes it goes further, and combines the negative idea in the same locution, as in *nolo*. This, however, happens but rarely; and here seem to end the verbal powers of this idiom. Not so with those of the Indian nations. While the Latin combines but few adjectives under its verbal forms, the Indians subject this whole class of words to the same process, and every possible mode of existence becomes the subject of a verb. The gender or genus—not, as with us, a mere division of the human species by their sex, but of the whole creation, by the obvious distinction of animate and inanimate—enters also into the composition of this part of speech, and the object of the active or transitive verb is combined with it by means of those forms which the Spanish-Mexican grammarians call *transitions*, by which one single word designates the person who acts, and that which is acted upon. The substantive is incorporated with the verb in a similar manner; thus, in the Delaware, *n'matshi* (I am going to the house); *nihilla pevi* (I am my own master, I am free); *tpisquihilleu* (the time approaches [proprietat hora]). The adverb likewise: *nachpiki* (I am so naturally); *nipahwi* (to travel by night [nocturnus]); *pachsunnumen* (to divide [something] equally), &c. What shall we say, then, of the reflected, compulsive, meditative, communicative, reverential, frequentative, and other circumstantial verbs, which are to be found in the idioms of New Spain and other American Indian languages? The mood is lost in the contemplation of the multitude of ideas thus expressed at once, by means of a single word, varied through moods, tenses, persons, affirmations, negation, transitions, &c., by regular forms and cadences, in which the strictest analogy is preserved.—(c) *Substantive Verbs*. It has been already ob-

served, that the Indian languages are generally destitute of the verb *to be*. In the Delaware, according to Zeisberger's Grammar, the verbs *to have* and *to be* do not exist, either as auxiliaries, or in the abstract substantive sense, which they present to an European mind. The verb *to have* always conveys the idea of *possession*, and *to be*, that of a *particular situation* of the body or mind; and they may each be combined, like other verbs, with other accessory ideas. Thus the verb *to have*, or *possess*, is combined with the substantive or thing possessed, as follows: *n'damochol* \* (I have a canoe); *nowikina* (I have a house). The idea conveyed by the substantive verb *to be*, is expressed by various combinations with other parts of speech; as, *ni n'damochol* (it is my canoe). It is also combined with the relative pronoun *awwen* (who); thus, *evenikia* (who I am), *evenikil* (who he is), &c.—(b) *Animate and Inanimate Verbs*. We have already alluded to this distinction of the verbs; but this requires illustration by examples. The two verbal forms, *nolhatton* and *nolhalla*, in the Delaware, both mean *I possess*; but the former can only be used in speaking of the possession of things inanimate, and the latter of living creatures; as, *nolhatton achquicvannissal* (I have or possess blankets); *cheeli kawcu n'nolhattowi* (many things I am possessed of; or, I possess many things); *wak neche-naunges nolhallau* (and I possess a horse). The letter *u*, at the end of the verb *nolhallau*, conveys the idea of the pronoun *him*; so that it is the same as if we said, *and a horse I possess him*. Again, in the verb *to see*, the same distinction is made; as, *lenno newau* (I see a man); *taholens newau* (I see a bird); but, in the case of an inanimate object, they say, for example, *wikwam nemen* (I see a house); *amochol nemen* (I see a canoe), &c. It is the same with other verbs, such, for example, as we call *neuters*: thus they say, *icka-shingieshin n'dallemous* (there lies my beast); but, on the other hand, *icka shingiesh-en n'tamahican* (yonder lies my hatchet or tomahawk). The *i* or *e*, in the last syllable of the verb, as here used in the third person, constitutes the difference which indicates, that the thing spoken of has or has not life.—(c) *Adjective Verbs*. This name is given by Mr Zeisberger to a description of words, respecting whose proper classification, he had much doubt. On the one hand, he found that there were in the Delaware language, pure adjectives, which receive different forms when employed in the verbal sense; such as *wulit*, *wulik*, *wulisso* (good, handsome, pretty); *wulitissu* (he, she, or it, is good, pretty, or handsome), and several others. But these are not very numerous. A great number of them are impersonal verbs, in the third person singular of the present tense; while others are conjugated through various persons, moods, and tenses. He decided, at last, to include them all in a list, which Mr Du Ponceau has called *adjective verbs*, in analogy with the name of another class, denominated *adverbial verbs*, which are formed by, or derived from adverbs. Examples: *guneeu*, long (it is); *guneeep*, it was long; *machkeu*, red (it is); *machkeep*, it was red, &c.—(d) *Adverbial verbs*. These are formed from adverbs; as, from *shingi* (unwillingly), they form the verb *shingilendam* (to dislike, to be against the will or inclination); from *shacki* (so far, so long) is formed *shackoochen* (to go so far off and no further).—(e) *Irregular Verbs*. These are chiefly of the class which we call *impersonal*; but they do not all belong to it. Of those which are called *irregular*, in the ancient and modern languages of Europe, that is,

\* The apostrophe in the word *n'damochol* indicates a *sheva* or mute vowel. Eliot, in his Massachusetts Grammar, denotes it by the English short *u*: *nuttappin* for *n'dappin*. (Du Ponceau.)

verbs whose different tenses and moods appear to have sprung from different roots—as in Latin, *sum, eram, fui*; in French, *aller, je vais, j'irai*; and in English, *I go, I went*—there are no examples in Zeisberger's Grammar of the Delaware, and probably there are none in that language. Mr Heckewelder, after giving an example of a Delaware verb, adds this remark: "In this manner, verbs are conjugated through all their moods and tenses, and through all their negative, causative, and various other forms, with fewer irregularities than any other language that I know of." The same regularity exists in the languages of South America. Molina says of that of Chile, "What is truly surprising in this language, is, that it contains no irregular noun or verb. Every thing in it may be said to be regulated with a geometrical precision, and displays much art with great simplicity, and a connexion of well ordered and unvarying grammatical rules, which always make the subsequent so much depend upon the antecedent, that the theory of the language is easy, and may be learned in a few days." This fact, as Mr Du Ponteau justly observes, is worthy of attention. Mr Zeisberger, in his list of irregular verbs, gives one example, *aski* (must), which has neither persons nor tenses, used thus: *aski n'witshema* (I must help him); *aski nayunap* (I was forced to carry him), &c. —(f) *Specific or concrete Character of the Indian Verbs.* It is a remark of Mr Heckewelder, that the Indians are more in the habit of using particular or specific, than generic terms. Their verbs, accordingly, partake of this character, and have numerous forms to express the particular or specific thing, which is the object of the action denoted by the verb. Thus, in the Delaware, *n'mitzi* (I eat), in a general sense; *n'mamitzi* (I am in the act of eating at this moment); the one is used in the indefinite, and the other in the definite sense; and a good speaker will never employ the one for the other. Again; *n'mitzihump* (I have eaten), *metshi n'gishimitzi* (I am come from eating), *n'dappi mitzi* (I am returned from eating). These three expressions are all past tenses of the verb *I eat*, and mean *I have eaten*; but a person just risen from table will not say, *n'dappi mitzi*; this can only be used after leaving the place where he has been eating, in answer to a person who asks him where he comes from. The word *n'dappi* is connected with the verb *apatshin* (to return). And here, in passing, another distinction is to be noticed; if the place from which the person comes is near, he says, *n'dappi*; but if distant, *n'dappa*. A more full illustration of this peculiarity of Indian words, was given some years ago by an example from the Cherokee language, published in the Massachusetts Historical Collections, vol. x., p. 121, of the second series, which we here extract. In that language, says one of the missionaries (the reverend Mr Buttrick), thirteen different verbs are used to express the action of washing: thus (pronouncing the words as in English)—

<i>Kuturo,</i>	I am washing myself, as in a river.
<i>Kulstala,</i>	— my head.
<i>Tastala,</i>	— another person's head.
<i>Kukusqud,</i>	— my face.
<i>Terkusqud,</i>	— another's face.
<i>Takatala,</i>	— my hands.
<i>Tatseyisula,</i>	— another's hands.
<i>Takatala,</i>	— my feet.
<i>Tatseyisula,</i>	— another's feet.
<i>Takungkulu,</i>	— my clothes.
<i>Tatseyungkulu,</i>	— another's clothes.
<i>Takutaga,</i>	— dishes, etc.
<i>Tasyura,</i>	— a child.
<i>Kuweli,</i>	— went.

This difference of words prevents the necessity of mentioning the object washed. So it is with the verbs *love, take, have, leave, die, weigh*, &c. The same thing is found in the languages of South and Middle America. Gilij informs us, that "to express *I wash my face*, requires a different word from that which would express washing *my feet, my hands*, &c.; and the old age of a man, woman, and of a garment, the heat of the body, of a fire, of the sun, and of the climate, have each a particular word. Agnis; in our language, and in many others (European), there is but one word, *mangiare*, for to eat; but in the Tamanacan, there are several, according to the thing eaten; *jacurá* is, to eat bread, or the cassava; *jemerá* (to eat fruit, honey); *janerá* (to eat meat), &c. We add an example from the Delaware, which is suggested by the above remark of Gilij, on the word *old*. This word, as Mr Heckewelder observes, is used by us in the most general sense; we say, an *old man, old horse, old house, old basket*, &c. The Indians, on the contrary, vary their expressions, when speaking of a thing that has life, and of one that has not; for the latter, instead of the word *old*, they use terms which convey the idea, that the thing has lasted long, that it has been used, worn out, &c. Examples; *kikey* (old, advanced in years), applied to things animate; *chovier* or *chovier* (old by use, wearing), &c.; *kikéyleno* (an old man, advanced in years); *kikéchum* (an old one, of the brute kind); *choviguan* (an old house), from *wikwan* or *wigwan*; *chowaren* (old shoes), from *maren* (moccasins or shoes); they say also, *pigihilleu* (torn by long use or wearing); *lógihilleu* (fallen to pieces), &c. The same remarks may be made on the word *young*; for instance, their general term for the *young*, the immediate offspring, is *mitshan*; *w'nitchanall* (his or her young or offspring, that have been born alive and suckled), and this applies to man, and beasts of the genus *mammalia*; but when they speak of the feathered kind, or when the young is produced from the egg by hatching, they say *aninshihilleu*, plural *aninshihileisak*, barely implying that the animals are *young feathered creatures*. We return to the verbs. (g) *The positive, negative, reciprocal, and other Forms of the Verbs.* All the verbs in these languages may be conjugated throughout, in the positive or affirmative, and the negative forms; as, in the Delaware, *n'dappi* (I am there); *matta n'dappi* (I am not there); and, in an example given by Mr Zeisberger, we have a curious instance of the care taken to preserve precision in some cases: on the verb *nul-lapevi* (I am free), he observes, that as this verb has the syllable *vi*, which, in general, indicates a negative form, its negative has *wiwi*. In the Massachusetts language, the negative form was made by interposing *oo* or *u* in the affirmative: as, *noowadchanumun* (I keep it), a (tool, garment, &c.); negative, *noowadchanum-oo-un* (I keep it not); *noowacntem* (I am wise); *noowacntam-ook* (I am not wise). The reciprocal form, in the Delaware, may be thus exemplified: Infinitive mood, *ahoalan* (to love); *n'dalois* (I love him); reciprocal, infinitive, *ahoaltin* (to love one another); *n'dahoaltineen* (we love one another); and, negatively, *matta n'dahoaltinurwneen* (we do not love one another), &c. *Reflected form*, *n'dabowale* (I love myself); *k'dahowala k'hakry* (thou lovest thyself), &c. *Relative form*, *cloweyu* (as what I say), from *n'dellowe* (I say). *Social form*, *wileen* or *wideen* (to go with), from *n'da*, or *n'da* (I go). *Causative form*, *pommauchoshreen* (to make to live), from *pommauchin* (to live); *nihitlapuchreen* (to make free), from *nihitlapewin* (to be free). *Continuous or habitual form*, *n'wawulamallan* (I am always well or happy), from *nulmaltan* (I am well or happy). *Adverbial form*, *epia* (where I am), from

*a'dippin* (I am there); infinitive, *achpin* (to be there). To these we add one other form, which, in the Massachusetts language, Eliot called the *instead form*, or *form advocate*; as, *koovadchanumwanshun* (I keep it for thee, I act in thy stead), from *koovadchanuk* (I keep thee). He adds, that this form is of great use in theology, to express what Christ hath done for us; as, *a'nuppoovonuk* (he died for me); *k'arppoonuk* (he died for thee), &c.—(i) *Personal Forms or Transitions* are, in fact, the manner of conjugating and declining all the verbs of each of the preceding classes. The remarkable method of effecting this has been already alluded to; but it requires a further development, in order to make it plain and intelligible to those who are accustomed merely to the structure of the European languages. Mr Heckewelder, in his correspondence with Mr Du Ponceau, explains it, in the Delaware language, in the following manner; which, we may add, is conformable with the views given of it, a century and a half ago, by Eliot, in his Grammar of the Massachusetts dialect: "I do not mean," says Mr H. to speak here of the positive, negative, causative, and a variety of other forms, but of those which Mr Zeisberger calls *personal*, in which the two pronouns, governing and governed, are, by means of affixes, suffixes, terminations, and inflexions, included in the same word. Of this I shall give you an instance from the Delaware language. I take the verb *shoalan* (to love), belonging to the fifth of the eight conjugations, into which Mr Zeisberger has very properly divided this part of speech:

## INDICATIVE, PRESENT, POSITIVE.

<i>W'ahala, I love</i>	<i>N'dahoalneen, we love.</i>
<i>k'ahala, thou lovest</i>	<i>K'dahoalohhimo, we love</i>
<i>W'ahala, or } he loves</i>	<i>Asholewak, they love.</i>

Now for the personal forms, in the same tense:

## First Personal Form.

<i>I. Singular.</i>	<i>Plural.</i>
<i>k'ahameli, I love thee</i>	<i>K'dahoalohhimo, I love you</i>
<i>k'ahala, I love him or her</i>	<i>N'dahoalawak, I love them.</i>

## Second Personal Form.

<i>THOU. Singular.</i>	<i>Plural.</i>
<i>k'ahali, thou lovest me</i>	<i>K'dahoalneen, thou lovest us</i>
<i>k'ahala, thou lovest him or her</i>	<i>K'dahoalawak, thou lovest them.</i>

## Third Personal Form.

<i>HE or SHE. Singular.</i>	<i>Plural.</i>
<i>k'ahali, he loves me</i>	<i>W'dahoaluna, he loves us</i>
<i>k'ahala, he loves thee</i>	<i>W'dahoaluna, he loves you</i>
<i>W'ahashali, he loves him</i>	<i>W'dahoalawak, he loves them.</i>

## Fourth Personal Form.

<i>WE. Singular.</i>	<i>Plural.</i>
<i>k'ahashalun, we love thee</i>	<i>K'dahoalohhimo, we love you</i>
<i>W'ahashalun, we love him</i>	<i>N'dahoalawak, we love them.</i>

## Fifth Personal Form.

<i>YE. Singular.</i>	<i>Plural.</i>
<i>k'ahashalimo, ye love me</i>	<i>K'dahoalohhimo, ye love us</i>
<i>k'ahashalimo, ye love him</i>	<i>K'dahoalawak, ye love them.</i>

## Sixth Personal Form.

<i>THEY. Singular.</i>	<i>Plural.</i>
<i>k'ahashalimo, they love me</i>	<i>N'dahoalohhimo, they love us</i>
<i>k'ahashalimo, they love thee</i>	<i>K'dahoalohhimo, they love you</i>
<i>W'ahashalimo, they love him</i>	<i>W'dahoalawak, they love them.</i>

In this manner, verbs are conjugated through all the moods and tenses, and through all their negative, causative, and various other forms, with fewer irregularities than any other language that I know of. We add an example from the Massachusetts language, as given by Eliot, who has used the English verb to *pay*, with the Indian inflexions, in order, as he expresses it, that "any may distinguish betwixt what is grammar, and what belongs to the word. And

remember (says he), ever to pronounce *pay*, because else you will be ready to read it *pau*. Also remember that *paum* is the radical word, and all the rest is grammar." The Indians, we believe, adopted the word *pay* into their language, as we adopt French and other foreign words into English.

## AFFIRMATIVE FORM.

## INDICATIVE MOOD.

## PRESENT TENSE.

<i>I. First Singular.</i>	
<i>Kup-paum-ush, I pay thee</i>	<i>Kup-paum-unumwo, I pay you</i>
<i>Nup-paum, I pay him</i>	<i>Nup-paum-og, I pay them.</i>
<i>THOU. Second Singular.</i>	
<i>Kup-paum-eh, thou payest me</i>	<i>Kup-paum-imun, thou payest us</i>
<i>Kup-paum, thou payest him</i>	<i>Kup-paum-og, thou payest them.</i>
<i>HE. Third Singular.</i>	
<i>Nup-paum-uk, he payeth me</i>	<i>Kup-paum-ukum, he payeth us</i>
<i>Kup-paum uk, he payeth thee</i>	<i>Kup-paum-ukou, he payeth you</i>
<i>Up-paum-uh, he payeth him</i>	<i>Up-paum-uh nah, he payeth them.</i>
<i>WE. First Plural.</i>	
<i>Kup-paum unumun, we pay thee</i>	<i>Kup-paum-unumun, we pay you</i>
<i>Nup-paum-unun, we pay him</i>	<i>Nup-paum-ounoog, we pay them.</i>
<i>YE. Second Plural.</i>	
<i>Kup-paum-imwo, ye pay me</i>	<i>Kup-paum-imun, ye pay us</i>
<i>Kup-paum-au, ye pay him</i>	<i>Kup-paum-og, ye pay them.</i>
<i>THEY. Third Plural.</i>	
<i>Nup-paum-ukgoos, they pay me</i>	<i>Nup-paum-ukmunooog, they pay us</i>
<i>Kup-paum-ukgoos, they pay thee</i>	<i>Kup-paum-ukoo-oog, they pay you</i>
<i>Up-paum-oub, they pay him</i>	<i>Up-paum-oub nah, they pay them.</i>

In consequence of this curious mechanism of the Indian verbs, as Dr Edwards has remarked, in his Observations on the Language of the Muhhekanew (Mohegan) Indians, they cannot say, *John loves Peter*, but must say, *John he-loves-him Peter*. Hence, when the Indians begin to talk English, they universally express themselves according to this idiom. It is further observable (he adds, in speaking of the Mohegan dialect, that the pronoun, in the accusative case, is sometimes, in the same instance, expressed by both a prefix and a suffix; as, *kthuwahunin* (I love thee); the *k* prefixed, and the syllable *in* suffixed, both unite to express, and are both necessary to express, the accusative case *thee*.<sup>178</sup> Mr Heckewelder informs us, in explaining this curious structure of the Indian verbs, that the form expressive of the pronoun governed, is sometimes placed at the beginning; as in *k'dahoatell* (I love thee), which is the same as *thee I love*, for *k*, from *ki*, is the sign of the second person: sometimes, however, the governing pronoun is placed first, as in *n'dahoala* (I love him), *n* being the sign of the first person: one of the pronouns, governing or governed, is generally expressed by its proper sign, *n'* for the first person *I*, *k'* for *thou* or *thee*, and *w* for *he* or *him*; the other pronoun is expressed by an inflexion; as in *k'dahoalohhimo* (I love you); *k'dahoalineen* (thou lovest us); *k'dahoalawak* (thou lovest them). It will be here perceived, that the governing pronoun is not always in the same relative place with the governed.—(*k*) *Voices, active and passive*. The Indian verbs have an active and passive form; as, in Delaware, *n'dahoala* (I love), *n'dahoalgussi* (I am loved); in the Massachusetts dialect, *noovadchan* (I keep you), *noovadchanit* (I am kept). From this passive form, says Eliot, verbals are often derived; as, *wadchannitwunk* (salvation), &c.—(*f*) *Conjugations*. The verbs may also be classed under different conjugations, the number of which varies in the different dialects. In the Delaware, Mr Zeisberger and Mr Heckewelder

<sup>178</sup> The reader should be apprized, that, in these and other examples from Delaware, the double consonants are used only to indicate that the prefix vowel is short, as in the German *immer*; and that the consonant is to be pronounced twice.

<sup>179</sup> Mr Du Ponceau, following the Spanish-American grammarians, calls these personal forms *transitions*. Eliot called them the *prefix forms*, in contradistinction to the simple forms, in which the act related to inanimate objects.

<sup>180</sup> The word *kthuwahunin*, in Mohegan, does not, at first view, appear to have an etymological affinity with the Delaware example above given, *k'dahoatell* (I love thee); but when we recollect, that the change of *i* into *n*, is a common distinction between these two dialects, and that *f* and *d* are constantly interchanged in languages, the affinity between these two words becomes more manifest.

made eight conjugations: the first ends in *in*, as *achpin* (to be there, in a particular place): the second, in *a*, as *n'da* (I go): the third, in *elendam*, and indicates a disposition of mind, as *wuleldam* (to be glad): the fourth, in *men*, as *n'pendamen* (I hear): the fifth, in *an*, as *ahoalan* (to love): the sixth, in *e* or *we*, as *n'dellowe* (I say): the seventh, in *in*, as *milin* (to give); it has no simple, active, or passive voice, and is only conjugated through the personal forms or transitions: the eighth, in *ton*, as *peton* (to bring); it has the simple active, but not the passive form, and has the personal indicative and subjunctive transitions. Their conjugations are as regular as those of any language that we know.—(m) *Tenses*. The writers on Indian grammar have usually made three tenses—present, past, and future; but, as Mr Heckewelder observes to Mr Du Ponceau, "You will be much mistaken, if you believe that there are no other modes of expressing actions and passions in the verbal form, as connected with the idea of time." This will be presently exemplified in some Indian verbs. The present and preterite require no particular illustration; but the future admits of a modification, which, to those who are conversant with the European languages only, is very remarkable. We take Mr Heckewelder's exemplification, abridged:

## INDICATIVE PRESENT.

## Positive Form.

N'dahoaltineen, we love one another  
K'dahoaltihimo, you love one another  
Ahoaltiwak, they love one another.

## Negative Form.

Matta n'dahoaltiwunee, we do not love one another  
Matta k'dahoaltiwihimo, ye do not love one another  
Matta ahoaltiwak, they do not love one another.

It is to be observed, that, in this negative form, *matta* (or *atta*) is an adverb, which signifies *no* or *not*, and is always prefixed; but it is not that alone which indicates the negative sense of the verb. It is also pointed out by *uw* or *wi*, which is interwoven throughout the whole conjugation; the vowel which immediately precedes being sometimes changed for the sake of sound, as from *aholtawak* (they love each other) is formed *ahoaltiwak* (they do not love each other). The reader will now readily understand the remarkable modification of the future tense above spoken of, which is a concordance in tense of the adverb with the verb. The future tense of the above negative example is—

Mattatah n'dahoaltiwunee, we shall or will not love each other  
Mattatah k'dahoaltiwihimo, you shall or will not love each other  
Mattatah ahoaltiwak, they shall or will not love each other.

Now, the termination *atah* or *tah*, in the verbs, indicates the future tense; but, by a peculiarity in these languages, it is sometimes attached to the verb, as in *ktahoaltiwitah* (thou shalt or wilt not love me), and sometimes to the adverb, as in the examples last above given, and to other parts of speech accompanying the verb. So they say, *mattatah n'dawi*, or *matta n'dawitah* (I shall not go). Mr Heckewelder observes, that, in deciding which form to use, the ear is the best guide. The same thing is noticed by doctor Edwards, in the Mohegan dialect. In the Massachusetts language, the future was expressed by a word signifying futurity, added to the indicative mood; as *mos*, *pish* (shall or will). In addition to these three tenses, we find by Mr Zeisberger's Grammar, that in the Delaware, the subjunctive mood has only a pluperfect in the active and passive voices, but not otherwise.—(n) *Moods*. These have generally been made conformable to the corresponding divisions in our own language—indicative, imperative, subjunctive, infinitive, with the participial form. In the Delaware, Mr Zeisberger has also given what he (or his translator) calls the *local-rela-*

*tive* mood; as, indicative, *n'da* (I go); *local relative*, *eyaya* (where or whither I go). Eliot, in the Massachusetts language, makes five moods—indicative, imperative, optative, subjunctive, or suppositive, and indefinite, or infinitive. We conclude the subject of the Indian verb with an example of a conjugation, from the Delaware, by which the preceding observations will be more fully illustrated; adding only the just remark made by Eliot more than a century and a half ago—that "the manner of formation of the nouns and verbs have such a latitude of use, that there needeth little other syntax in the language." After this example from the Delaware, we shall give some parts of a conjugation from the Cherokee language, which belongs to an entirely different stock, and has some peculiarities still more extraordinary than those already given from other languages. (The limits will not allow us to insert a whole conjugation of the verb, in its various modifications of the masculine, animate, affirmative, negative, and other forms. We shall therefore only give so much as will exhibit the personal forms or transitions, which have been above spoken of.

## AHOALAN, to love.

## PERSONAL FORMS (OR TRANSITIONS)—POSITIVE

Ahoalilneenutsh, if or when they shall or will love thee	Ahoalilneenutsh, if or when they shall or will love you
Ahoalilneenutsh, if or when they shall or will love him	Ahoalilneenutsh, if or when they shall or will love them.

We have remarked above, that the Indian verb has various modifications in different dialects. Those of the Delaware language have been sufficiently explained for the purposes of a general view; and we shall now further develop this curious subject, by exhibiting some of the peculiarities of the verb, in the Cherokee, or, more properly, *Tsalalakee* language, which belongs to an entirely different stock, and appears not to have the least etymological affinity with the Delaware, though its grammatical forms, generally speaking, are similar. In the course of our remarks, we shall occasionally advert to some of these points of resemblance and, as well as to the difference between the two.—(a) *Numbers*. One of the peculiarities which first strikes us, is, that, besides the singular and two plurals, which are found in the Delaware, the Cherokee has also a proper *dual* number, both in its verbs and its nouns and pronouns. This dual is again subdivided, in its first person, into two distinct forms; the first of which is used when one of two persons speaks to the other, and says, for example, *We two* (i. e. thou and I), *will do such a thing*; the second form is used when one of two persons speaks of the other to a third person, and says, *We two* (i. e. he, and I) *will do such a thing*;\* for example, *inaluiha* (we two [i. e. thou and I] are tying it); *awataluiha* (we two [i. e. he and I] are tying it). So in the dual of the nouns and pronouns—*kinitawti*, our father (i. e. of thee and me); *awkinitawti*, our father (i. e. of him and me).—(b) *Pluralized or Multiplicative Form*. We mean by this denomination a form which indicates, that the action expressed by the verb is predicated of more than one object, or that the object of the verb is understood in the plural number. This modification is effected through all the tenses and numbers of the verb, by means of the common plural prefixes, *t*, *te*, *ti*; for example, *katitaw'ti* (I use a spoon); *tekatitaw'ti* (I use spoons); *tsigawewati* (I see [a thing]); *teatsigawewati* (I see [things]); *tsitigiti* (I eat [thing]); *teatsitigiti* (I eat [things]), &c.—(c) *Habitual or Periodical Form*. This is a form or conjugation, which expresses the being in the habit or custom of doing an act, or the doing of it regularly, periodically, &c.; for example, the common form of the verb *tsikeyu* means *I love him*; but, in the *habitual* form or mode, it is *tsikeyusaw* (I love him habitually, or, am in the habit of loving him); again, *galuiha*, in the common form, means *I tie*, or *am tying* (it); but *galungihaw-i* means *I tie habitually*, &c. This form appears to correspond to what Mr Zeisberger, in the Delaware, calls the *continuous* form.—(d) *Conjugations*. These have not yet been sufficiently investigated to furnish us with a satisfactory classification. Some have

\* In writing the Cherokee words, in these examples, we are obliged to express the sounds by the best approximations that our English alphabet affords. The true sounds cannot, in every instance, be perfectly expressed by any other than the national *syllabic alphabet*, if we may so call it, which was invented by a native Cherokee, Guest, who was unacquainted with any other language than his own, but has analyzed that like a philosopher, and has devised an ingenious set of characters to denote all its elementary sounds, which he has reduced to eighty-five, and has denoted by that number of syllabic characters. We cannot employ this native alphabet here, as it would be wholly unintelligible without a good deal of study. To express the *nasal*, which is so common in the language, we have used the *u* in the description above, and *u* in the table of the verb; but the reader should be apprized, that the true sound is more like the French nasal *un*; like *un* in the first syllable of our words *uncle*, *hunger*, as heard the instant before the tongue touches the roof of the mouth. The short *u* is to be sounded, as in *but*, *nut*, &c. The *u* is to be sounded as in English. The other vowels are to have the foreign or Italian sound, as in *far*, *there*, *machine*, *note*, *rule*; and the consonants as in English and its kindred languages. In writing this language with our alphabet, the *g* and *k* are often used promiscuously; as are also the *d* and *t*. The double consonant *kt* is also used for the sound of *tt*.

made them six in number.—(e) *Moods*. These have been described as five in number, corresponding to our indicative, imperative, subjunctive, potential (relating simply to power or ability) and infinitive; to which, in the opinion of the same writers, may be added a sixth, denoting *liberty to do an act*; but this classification is not yet sufficiently established.—(f) *Tenses*. An exact arrangement of the tenses, as well as the moods, is still wanting. Besides the three general divisions of present, past, and future, the Cherokee has several subdivisions of time; but these subdivisions have not yet been settled with much exactness, so as to enable us to compare them with the European verb. The perfect or past tense, however, has a very remarkable subdivision into two forms, which may, properly enough, be called *two perfects*. They are used not to mark a difference in time, but one of them indicates, that the person speaking was present, or an eye-witness, or conscious of the fact which he relates to have taken place; and the other, that he was absent, or not conscious, but has learned it since by information, discovery, &c. They might be denominated the *absential* and *presential* perfect, or, to avoid the double signification of the word *present*, we might call them simply the *perfect* and the *absent perfect*. The former ends in the nasal *u*, and the latter in *é* or *éi*. Examples: perfect, *u-hlu* (he killed him)—speaking of a killing when the speaker was present, or conscious of the fact; absent perfect, *u-hléi* (he killed him)—speaking of a killing when the speaker was absent. In the following conjugation of the present tense of a Cherokee verb, we are obliged to confine ourselves, as in the case of the Delaware example, to the *animate* form:

#### Conjugation of the Present Indicative of a Cherokee Verb.

##### INDICATIVE MOOD.

###### Present Tense.

NEUTER GENDER; THE OBJECT OF THE VERB BEING IN THE SINGULAR NUMBER.

Singular.		Plural.	
1 person.	Galuiha, I am tying it	1 & 2.	Inaluiha, ye and I are tying it
2 do.	Haluiha, thou art tying it	1 & 3.	Awataluiha, they and I are tying it
3 (pres.)	Kaluiha, he is tying it	1 & 2.	Inaluiha, ye and I are tying it
3 (abs.)	Gahluha, he is tying it.	3; (pr.)	Tawaluiha, they and I are tying it
1 & 2.	Inaluiha, thou and I are tying it	3 (abs.)	Awataluiha, they and I are tying it.
1 & 3.	Awataluiha, he and I are tying it		
2.	Istaluiha, ye two are tying it.		

NEUTER, DUAL AND PLURAL; THE OBJECT PLURAL.

Singular.		Plural.	
1.	Tegaluiha, I am tying these things	1 & 2.	Tetaluiha, ye and I are tying them (these things)
2.	Tahaluiha, thou art tying these things	1 & 3.	Tawaluiha, they and I are tying these things
3.	Tekahluha, he is tying these things.	2.	Tawaluiha, ye are tying them
Dual.		3 (pr.)	Tewaluiha, they are tying them
1 & 2.	Tenaluiha, thou and I are tying these things	3 (abs.)	Dawaluiha, they are tying them.
1 & 3.	Tawaluiha, he and I are tying these things		
2.	Tetaluiha, ye are tying these things.		

THE FIRST PERSON SINGULAR, OBJECTIVE.

Singular.		Plural.	
2.	Skwaluiha, thou art tying me	2.	Skwaluiha, ye are tying me
3 (pr.)	Takwaluiha, he is tying me	3 (pr.)	Kakwaluiha, they are tying me
3 (abs.)	Akwaluiha, he is tying me.	3 (abs.)	Gakwaluiha, they are tying me.
Dual.			
2.	Skinaluiha, ye two are tying me.		

\* We use the term *present* to denote the expectation and intention, as the part of the speaker, that the present person should hear. The term *absential* is used when the speaker has no such intention, or is indifferent respecting it.

† 1 and 2 persons; 1 and 3 persons. This is, perhaps, a proper distinction between these two forms in the dual and plural, either of which would be expressed by the first person in English.

‡ The dual and plural of the third person are always the same. Where the dual and plural numbers are given separately, in the other persons, we have omitted the dual of the third person, because it always agrees with the plural.

§ Where a person is wanting, it will soon plainly be revealed from the nature of the case, as the first person is in the instance.

## FIRST AND SECOND PERSONS DUAL, OBJECTIVE.

Collective.*	Distributive.*	
No. 1 (p.) Taktalulsha,	Teaktalulsha,	He is tying thee and me
3 (du.) Oinalulsha,	Teginalulsha,	He is tying thee and me.
No. 2 (p.) Tekhmalulsha,	Tekhmalulsha,	They are tying thee and me
3 (du.) Tegmalulsha,	Tegmalulsha,	They are tying thee and me.

## FIRST AND THIRD PERSONS DUAL, OBJECTIVE.

Collective.	Distributive.	
No. 1	Shamalulsha, Teaktalulsha,	Thou art tying him and me
3 (p.)	Takhalulsha, Tetawhalulsha,	He is tying him and me
3 (du.)	Awgalulsha, Teawgalulsha,	
No. 2	Shamalulsha, Teaktalulsha,	Ye two are tying him and me.
No. 3	Shamalulsha, Teaktalulsha,	Ye are tying him and me
3 (p.)	Kakhalulsha, Tekahhalulsha,	They are tying him and me.
3 (du.)	Oaghalulsha, Tegawgalulsha,	

In the same analogy, there are distinct forms for the English expressions, "he is tying you and me," "they are tying you and me," "thou art tying them and me," "he is tying them and me," "ye are tying them and me," "they are," &c.; "I am tying thee," "he is," &c., "he and I, they and I, they are," &c.; "I am tying you two," "he is," &c., "they are," &c.; "I am tying you (all in the plural), he is, we are, they are," &c.

*Adverbs, Prepositions, Conjunctions, Interjections.* These parts of speech require no particular remarks. According to some writers, all of them are to be found, as distinct parts of speech, in the Indian languages. But others, on the contrary, affirm that some of them are wanting in particular dialects; as, for example, it is said that the Cherokee has no *prepositions*; though they are to be found in the Delaware. —We conclude this article, which the novelty of the subject has led us to extend beyond our original plan, with a few miscellaneous remarks on the Cherokee language. The name of this nation, we would observe, is *Tsalaki* (pronounced nearly like *Tsullakee*), the last syllable of which is often written *gi*; the sound of this final syllable being neither exactly our *k* nor *g*, but an intermediate sound between those two. The English name *Cherokee*, it is supposed, was originally taken from one of the dialects in which the sound of *r* occurs, *Tsaraki* or *Tsurakee*. This name is believed not to be significant; but, if originally so, the signification of it is now lost. Some names of places among them have been much more changed than this national name, by our English orthography; as *Chetahochie* from *Tsatuhutsi* (which may have been a Creek name), *Coosacaytee* from *Kuawetiyi*; *Tellico* from *Taliqua*; *Hightower* from *Ilawa*, pronounced *Etawra*, &c. Among the words of relationship, *brother*, *sister*, &c., we find some terms that have a different signification, according as they are used by a man or woman. Example: the word *ungkilaw*, used by women, signifies *my brother*; but used by men, it means *my sister*; and the women exclusively use *ungkilaw* for *my sister*. It is said that this language has no relative pronoun. Like the Indian languages in general, it is highly compounded, or, as Mr Du Ponceau first very happily denominated this class, *polysynthetic*. There are, as we should naturally expect, therefore, but few monosyllables; some say, only fifteen in the whole, which are all interjections and adverbs, with the exception of one, the monosyllable *ae*, which is sometimes a pronoun and sometimes an adverb. Of its polysynthetic character we are able to give one very remarkable example, in a *single word*, which, for perspicuity's sake we have separated into its syllables; viz. *Wi-ni-taw-ti-gi-na-li-akaw-lung-ta-aw-ne-li-ti-se-ti*; which may be thus rendered — "They-will-by-that-time-have-nearly-done-printing- [favours] from-a-distance-to-thee-and-to-

me." It is said that the expression "*I ought to tie thee or him*," cannot be translated into Cherokee; and that the nearest approach they can make to it is, by a circumlocution, which means, "it would be right for me to tie, or it would be wrong for me not to tie," &c. It is also a feature of this language, that all its words end with a *vowel* sound; and this has enabled the 'philosopher' Guest to reduce its elementary syllables to so small a number as eighty-five, and to adopt a *syllabic* alphabet. Their neighbours, the Choctaws (more properly *Chaktaws*), having a language which is wholly different in this particular, have not been able to adopt a similar alphabet.—But we are admonished that our limits forbid any further details; and we only add, that this very general survey of these curiously constructed languages "will convince every reader," as is justly remarked by the American philologist, Mr Du Ponceau, "that a considerable degree of art and method has presided over their formation. Whether this astonishing fact (he adds) is to be considered as a proof—as many are inclined to believe—that this continent was formerly inhabited by a civilized race of men, or whether it is not more natural to suppose, that the Almighty Creator has endowed mankind with a natural logic, which leads them, as it were, by instinct, to such methods in the formation of their idioms as are best calculated to facilitate their use, I shall not at present inquire. I do not, however, hesitate to say, that the bias of my mind is in favour of the latter supposition, because no language has yet been discovered, either among savage or polished nations, which was not governed by rules and principles which nature alone could dictate, and human science never could have imagined."—For further information on this novel and curious subject, we refer our readers to the following as the most important works: *Historical and Literary Transactions of the American Philosophical Society* (vol. i. 8vo, Philadelphia, 1819); in which the reader will find the correspondence of Mr Du Ponceau and Mr Heckerwelder, and also a copious list of manuscript grammars, dictionaries, and other works on the Indian languages; Eliot's *Grammar of the Massachusetts Indian Language*, first printed in 1666, Cambridge, New England, and reprinted in 1822, by the Massachusetts Historical Society, in their Collections; Edwards's *Observations on the Language of the Muh-hekannew* [Mohican] *Indians*, first published in 1788, and reprinted by the same society in their Collections for 1823; Zeisberger's *Grammar of the Delaware or Lenape Language*, translated by Mr Du Ponceau, and published by the American Philosophical Society, in their Transactions, vol. iii.—the most important of all the recent publications, to the student; and the *Cherokee Phoenix*, a newspaper printed by natives of that nation, in their own and the English languages. The circumstance of the alphabet being syllabic, and the number of syllables so small, is the greatest reason why the task of learning to read the Cherokee language is so vastly easier than that of learning to read English. An active Cherokee boy may learn to read his own language in a day; and not more than two or three days are ordinarily requisite. To read is only to repeat successively the names of the several letters; when a boy has learned his alphabet, he can read his language.

INDIANA; one of the United States of America, bounded N. by lake Michigan and the Michigan Territory, E. by Ohio, S. by Kentucky, from which it is separated by the Ohio river, and W. by Illinois; lat. 37° 50' to 41° 45' N.; lon. 84° 45' to 88° W.; length from north to south 270 miles, breadth 220; square miles 36,000; population in 1800, 4651; in 1810, 24,520; in 1820, 147,178; and, in 1830,

\* Collective; Distributive. Collective, *shamalulsha* (he ties us two together). Distributive, *teaktalulsha* (he ties us two separately). This distinction refers to the object of the actions, and runs throughout the dual and plural numbers of all the persons. The two forms, however, are not both in common use with every verb; but the one or the other, according as the nature of the action relates to objects, collectively or separately considered.

341,582, of whom, at the last period, 3562 were free blacks. There are, besides, about 4000 Indians of the Miami, Eel river, Pottawatamie, and Chippeway tribes. These Indians receive annuities from the United States, by virtue of treaties for the cession of lands, amounting to about £9000. The state is divided into fifty-nine counties. The seat of government is at Indianapolis, a town situated near the centre of the state, the settlement of which was begun in 1821. The largest town is Vincennes, which is situated on the river Wabash, and was originally settled by French emigrants from Canada. The other chief towns are Madison, Corydon, Jeffersonville, and Vevay. The principal rivers are the Ohio, which forms the southern boundary; the Wabash, which, after passing through the whole width of the state, forms part of its western boundary; the White river, the Whitewater, the Maumee, and the Petohra. A canal for uniting the navigable parts of the Wabash river with lake Erie, is proposed, and a grant of land for effecting the object has been made by congress, but the work is not begun. There are no mountains in Indiana; the country, however, is more hilly than Illinois, particularly towards the Ohio river. A range of hills, called the *Knoxs*, extends from the falls of the Ohio to the Wabash, in a south-west direction, which, in many places, produces a broken and uneven surface. North of these hills lie the *flat woods*, seventy miles wide. Bordering on all the principal streams, except the Ohio, there are strips of bottom and prairie land; both together from three to six miles in width. Between the Wabash and lake Michigan, the country is mostly champaign, abounding alternately with woodlands, prairies, lakes, and swamps. A range of hills runs parallel with the Ohio, from the mouth of the Great Miami to Blue river, alternately approaching to within a few rods, and receding to the distance of two miles. Immediately below Blue river, the hills disappear, and there is presented to view an immense tract of level land, covered with a heavy growth of timber. North of the Wabash, between Tippecanoe and Ouitanan, the banks of the streams are high, abrupt, and broken, and the land, except the prairies, is well timbered. Between the Plein and Theakiki, the country is flat, wet, and swampy, interspersed with prairies of an inferior soil. The sources of rivers are generally in swamps or lakes, and the country around them is low, and too wet for cultivation. There are two kinds of prairies,—the river and the upland prairies. The former are bottoms, destitute of timber, and are said to exhibit vestiges of former cultivation; the latter are from 30 to 100 feet more elevated, and are far more numerous and extensive. Some of them are not larger than a common field, while others extend further than the eye can reach. They are usually bounded by heavy-timbered forests, and not unfrequently adorned with copses of small trees. In spring and summer, they are covered with a luxuriant growth of grass and fragrant flowers, from six to eight feet high. The soil of these plains is often as deep and fertile as the best bottoms. The prairies bordering on the Wabash are particularly rich. Wells have been dug in them, where the vegetable soil was twenty-two feet deep, under which was a stratum of fine white sand. The ordinary depth is from two to five feet. The principal productions of this state are wheat, Indian corn, rye, oats, barley, buck-wheat, potatoes, pulse, beef, pork, butter, whiskey, and peach brandy. Not far from Big Blue river, there is a large cave, the entrance of which is on the side of a hill, that is about 400 feet high. Here are found great quantities of sulphate of magnesia or Epsom salt, and of nitre, &c. The climate is generally healthy and pleasant, resembling that of Ohio. The Wabash is frozen over in the winter.

With the exception of the French settlement at Vincennes, which formed a solitary village for near a century, there were no civilized inhabitants within the present limits of the state, until near the commencement of the present century. From that period, the population has increased rapidly, chiefly by emigration from the other states. A territorial government was formed in 1800, and, in 1816, the state was admitted into the Union, and the present state constitution was formed. Under this constitution, a governor and lieutenant-governor are chosen by the people once in three years. There is a general assembly, consisting of a senate, the members of which are chosen for periods of three years, a third part being elected annually; and of a house of representatives, the members of which are elected annually. The present number of senators is twenty-three, and of representatives sixty-two. The number of representatives may be increased to 100, and of senators to half the number of representatives. The judges of the supreme court are appointed by the governor, with the consent of the senate; the presidents of the circuit courts by the legislature; and the associate judges are elected by the people. Justices of the peace are elected by the people. A thirty-sixth part of the land, in each township, is reserved, by a compact between the state and the United States, for the support of education, and reservations of land have been made for the support of a college, which is established at Bloomington, but which is not yet in operation. The national road, which commences at Cumberland in Maryland, and passes through Pennsylvania, Virginia, and Ohio, will run through the centre of this state, from east to west. The construction of the road in this state is yet but little advanced.

INDIANAPOLIS; a town in Indiana, and the seat of government of the state. It is situated in Marion county, on the west fork of White river. It was laid out in 1821, and in the following year had forty houses. It has increased rapidly from that period, and became the seat of government in 1825.

INDICATIVE; that mode of the verb in which something is said positively; hence it has also been called *modus positivus*, as distinguished from the subjunctive.

INDICATOR (*cuculus indicator*, Linn.). This bird, which is a native of Africa, in its external appearance does not differ much from the common sparrow, except that it is somewhat larger. It is peculiar for its faculty of discovering and indicating to man the nests of wild bees. Being itself extremely fond both of honey and the larvae, knowing that when a nest is plundered, some will fall to its share, it is always willing to act as a guide in the search for them. The morning and evening are its usual times of taking food, at least it then appears most solicitous to engage the aid of man in satisfying its appetite. A grating cry of *cherr, cherr*, may then be heard, which generally brings somebody to the spot where it is perched, when the bird, incessantly repeating its cry, flies slowly towards the quarter where the swarms of bees is to be found. When the nest is at some distance, the bird makes long flights, waiting for its coadjutor between them, and calling him to advance; but in proportion as it approaches, its flights are shorter and its cry more earnest. When it arrives at the nest, it hovers over the spot for the space of a few seconds, after which it retires to some adjoining bush, and patiently awaits its reward in silence. Its followers, having plundered the nest, leave it a considerable portion of that part of the comb containing the young bees, this being its most favourite morsel. This account, which is condensed from Sparmann, was severely animadverted upon by Bruce and other

writers; but Barrow, who visited the southern extremity of Africa at a subsequent period, fully confirms its truth. He says, that every one there is too well acquainted with this bird to entertain any doubts of the fidelity of Sparmann's narrative. It is also confirmed by Le Vaillant, who states that, on account of the important services which it renders to the Hottentots, they were very unwilling that he should destroy one of them.

**INDICTION**, in chronology; a period of fifteen years, reckoned in succession, and used by the Romans for appointing the time for the payment of certain taxes. Three sorts of indiction are mentioned; 1. the *Cæsarean*, which fell on the 8th of the calends of October, or the 24th of September; 2. the indiction of Constantinople, which was instituted by Constantine, A. D. 312, and began on the 1st of September; and 3. the pontifical or Roman, which begins on the calends of January. It has no connexion with the motions of the heavenly bodies. We find ancient charters in England also dated by indictions.

**INDICTMENT**. An indictment, according to the English law, is a written accusation of one or more persons for a crime or misdemeanour, preferred to, and presented upon oath by a grand jury, to a court. In determining whether there is a reasonable cause to put the accused upon his trial, the grand jury hear evidence in support only of the charge; and if twelve of them are satisfied of the truth of the charge, the indictment is then said to be found, and is publicly delivered into court. If the grand jury think the accusation groundless, the accused is discharged; but a new bill of indictment may be preferred to a subsequent grand jury.

**INDIES**, *WEST*. See *West Indies*.

**INDIGESTION**. See *Dyspepsia*.

**INDIGO**. The knowledge of this most valuable vegetable substance, which forms an important part of East and West Indian commerce, and is beginning to receive considerable attention as an American production, is alike interesting to the chemist and to the dyer. The ancients were acquainted with it under the name of *indicum*. Pliny knew that it was a preparation of a vegetable substance, though he was ignorant of the plant which furnished it, and of the process by which it was prepared. From its colour, and the country from which it was imported, some authors call it *atramentum indicum*, and *indicum agrum*. The American name is *nil*, or *anil*, from which the Portuguese have adopted their *anileira*, the other European nations generally call it *indigo*. The Arabian name is *nile*, and the Chinese, *tien laam*, or *sky blue*.

In treating of indigo, it will be the most convenient to explain, in the first place, its physical and chemical properties, and afterwards to allude to the sources from whence it is derived, and the method by which it is manufactured. As it is found in commerce, it presents the form of little square or oblong cakes, of an intense blue colour, approaching to black; is brittle and friable; rather light, and without taste or odour. It is volatile, with a disagreeable odour, subliming at 550° F.,—a degree of heat near that at which it is decomposed. Its vapour is of a rich violet-red colour, and condenses by cold into delicate acicular crystals, which consist of perfectly pure indigo. Water, by being boiled on indigo, dissolves only about a ninth or twelfth its weight; the solution is of a reddish-brown colour, and contains what may be called the *extractive* part of the substance; but the colouring matter remains unaltered, except in having assumed a brighter hue. Alcohol and ether, when digested upon it, also are attended with similar effects. Sulphuric acid is the only single agent that

dissolves indigo without destroying its colour. When it is put into this acid, a yellow solution is at first formed, which, after a few hours, acquires a deep blue colour. From the solution, diluted with water, potash and its sulphate throw down a deep dark-blue precipitate, capable of imparting to water, containing only  $\frac{1}{1000}$  of its weight, a distinctly blue tinge. It is no longer subject to vaporization, however; from which circumstance, and its property of solubility in water, it is inferred to be a different substance from indigo, and has received the name of *cerulin*. Its composition is believed to be one equivalent of indigo and four of water. When properly diluted with water, it forms the *liquid blue*, or *Saxon blue*, of the dyers. Another compound of indigo and water, under the name of *phenecin* (from *φαινε*, purple), is obtained when water is added to a solution of indigo in sulphuric acid, which has been suffered to stand for several hours, till it has lost its yellow colour, and become blue. It appears to consist of one equivalent of indigo, and two of water. In the formation of these substances, indigo is conceived to combine with water; but whether the water is afforded by the sulphuric acid, or whether the sulphuric acid operates merely to prepare the indigo for combining with water afterwards, is not yet fully determined. When indigo, suspended in water, is brought into contact with certain deoxidizing agents, it is deprived of a part of its oxygen, becomes green, and is rendered soluble in water, and still more so in the alkalies. It recovers its former colour, however, on exposure to the air, by again absorbing oxygen of  $\frac{1}{2}$  or  $\frac{1}{3}$  of the whole weight of the resulting indigo. Its deoxidizement is effected either by allowing it to ferment along with bran, or other vegetable matter, or by decomposing in contact with it the protosulphate of iron, by the addition of lime. Substances dyed by deoxidized indigo receive a green tint at first, which becomes blue by exposure to the air. This is the usual method of colouring cloths by means of indigo, which, when fully oxidized, affords a permanent dye, not removable by soap or by acids. Chlorine, whose power in extinguishing vegetable colours is universal, destroys the colour of indigo; and, from the known fact that the same quantity of free chlorine discolours always the same quantity of pure indigo, a solution of indigo in sulphuric acid has been employed for measuring the strength of solutions of chlorine and of chloride of lime, in order to regulate their application to the art of bleaching; and, reciprocally, a solution containing a known quantity of chloride of lime may be employed as a test of the strength or value of indigo. Indigo, purified by sublimation, is composed of 73.26 carbon, 13.81 nitrogen, 10.43 oxygen, and 2.50 hydrogen.

Indigo may be said to be a rare production of the vegetable kingdom, it hitherto having been found only in a small number of species belonging to the genera *indigofera*, *isatis*, and *nerium*; but it is almost exclusively from the first of these that the indigo of commerce is extracted. The species of *indigofera* are leguminous plants, herbaceous or shrubby, with alternate and generally pinnate leaves, and small blue, purple, or white flowers, ordinarily disposed in axillary racemes. They are very numerous in the equatorial regions of the globe. The species most commonly cultivated are the *I. anil*, a native of tropical America, according to the latest authority, but now cultivated even in the East Indies; the *I. tinctoria*, also cultivated in both Indies; and the *I. argentea*, which is the species employed in Barbary and Egypt. The *I. tinctoria* is the species most abundantly cultivated.

In describing the culture of the indigo plant, and the mode of manufacturing the indigo, we shall draw

our particulars mainly from the methods pursued in the East Indies, where, through the well directed efforts of the English, this article is prepared in its greatest perfection. The plant requires a rich, light soil, and a warm exposure. It succeeds best on newly cleared lands, on account of their moisture; it requires protection against high winds, and needs irrigation in times of drought. The ground, after being properly prepared for the reception of the seed by ploughing, is sown pretty thickly, the time of sowing being so chosen that rain may fall upon the plant as soon as it shows itself above the ground, by which it is not only greatly invigorated, but cleansed from those innumerable insects which otherwise are liable to destroy it. From this time, comparatively little rain is needed; for the dews are so copious as to supply nearly all the moisture required; and, besides, its spindle-shaped root, which descends into the ground perpendicularly, to the depth of nearly three feet, enables it to endure temporary droughts. The prevalence of cloudy weather and much moisture, however, cause the indigo plant to thrive more luxuriantly, but occasion a great deficiency in the colouring matter, which, as it contains an extraordinary quantity of carbon, requires the plant to decompose carbonic acid gas very abundantly,—an operation which it is unable to perform when deprived of the direct influence of the sun's rays. As the young shoots furnish larger and more numerous leaves, it is usual to plant every year; but the Egyptians, who seem to cultivate it most successfully, plant only every third or fourth year. As the plant approaches to maturity, the leaves undergo a sudden change in colour, from a light to a dark green. As soon as this change is observed, the branches are severed from the parent stem early in the morning, and spread out in the sun till the afternoon, by which time they become sufficiently dry to be beaten from the branches by a stick. The leaves, so separated, are housed in warehouses, closely packed, and well trodden down by natives. The plants, from which the leaves have been severed, send forth a new crop, which is gathered, when mature, like the first. Rain, however, is necessary after the cutting, to enable the plant to shoot again in a thrifty manner. The cuttings, in a favourable season, are repeated three or four times, after which the ground is ploughed up for another sowing; but each successive growth of the branches produces an increased deterioration of the qualities of the leaves, so that one part of the leaves of the first cutting yields as much indigo as two parts of the third crop. The dried leaves are not immediately used, but are kept packed for one month, during which time they suffer a material change, which is indicated by their having passed to a light lead colour. By additional keeping, the lead colour gradually darkens, until it becomes black. The maximum quantity of indigo is to be obtained when the lead colour is effected; and any delay in extracting it, after it has reached this point, is attended with a loss in the quantity of the indigo. The lead colour, however, does not appear in a month after the leaves are gathered, unless, from fear of rain, or any other cause, they were cut before being ripe; and, on the other hand, if the cutting was deferred till after the plant was fully ripe, the leaves will not require to be kept so long. The dried leaves, after having suffered the change of colour alluded to, are transferred to the steeping vat (an uncovered reservoir, thirty feet square, and twenty-six inches deep, constructed of brick, and lined with stucco), where they are mingled with water, in the proportion of about one volume of leaves to six of water, and allowed to remain two hours. The great affinity of indigo for oxygen is

here very manifest, in the quick change of the colour of the leaves which float on the surface, and are exposed to the action of the atmosphere, to a blackish blue, when contrasted with those below, which remain unchanged. On this account, the vat is frequently stirred, so that the floating leaves may be immersed. After two hours' infusion, the water, which, from the solution of imperfectly oxygenated indigo, has acquired a fine green colour, is allowed to run off from the leaves, through strainers, into the beating-vat, where it is agitated by the paddles of ten or twelve natives for about two hours, during which time the fine green liquor gradually darkens to a blackish blue. This part of the process requires a longer or a shorter time, depending on the former preparation of the leaf, and the immediate influence of the sun. The criteria for judging when it is completed are derived from the incipient separation of the particles of indigo, which become visible by pouring a small quantity of the fluid into a white earthen dish. At this time, lime-water is thrown into the vat, and thoroughly agitated with the whole mass of fluid. The mass is then left to subside for the space of three hours, when the supernatant liquid, which is of a fine bright Madeira colour, is withdrawn, by orifices in the vat, at different heights. The indigo is then removed to the covered part of the manufactory, where it is put on a straining cloth, and allowed to drain throughout the night. On the following morning, it is transferred to a copper boiler, where it is mingled with a quantity of water, and raised to ebullition. As the mass is gradually heating, a quantity of scum rises, which is immediately removed, and as soon as the whole is brought to the boiling point, the fire is withdrawn. The contents of the copper are retaken to the strainers, and the drained indigo is then divided into small portions, and each portion well worked by the hands of the natives, in order to free it from air bubbles. It is then carried to the pressing-boxes, which are usually square, and of sufficient depth to leave the cake about two inches and a quarter in thickness. By means of a powerful screw, the water is separated from the indigo; the cakes are gradually dried in the shade, and thus rendered fit for exportation.

In the West Indies and America, the old process formerly employed in India, of fermenting the leaves as soon as cut, instead of drying them, and obtaining the indigo by simple infusion, is still in use. The plant is allowed to stand until it is fully in blossom, when it is cut down with rape-hooks, tied in loads, and carried to the works, where it is deposited in strata in the steeping vat. As soon as the vat is filled with the green plant, water is admitted sufficient to cover it, and the whole is left to digest and ferment, until the greatest part of the pulp is extracted, without letting the tender tops run to putrefaction; and it is the management of this point which occasions the planter the greatest difficulty; for, if he draws off the water but two hours too soon, he inevitably loses the greatest part of the pulp, and if the fermentation runs but two hours too long, the whole is spoiled. Nine-tenths of the indigo of the United States, it is asserted, are more or less injured by an excessive fermentation. To ascertain the due degree of fermentation, the workman draws out, from time to time, a handful of the plant, and, when he finds the tops grow very tender and pale, and observes the stronger leaves change their colour to a less lively pale, he draws the liquor off without delay. An experienced manufacturer will also form a tolerable estimate of the degree of fermentation by the grass of the infusion, of which he frequently beats a hit in a silver cup. When the pulp is believed to be extracted, the infusion is drawn off into the beating-

ent, after which it is treated in a manner similar to that above described. It is computed that British India supplies three-fourths of all the indigo brought into European markets. For an account of the indigo obtained from the *Isatis tinctoria*, see *Wood*.

**INDIRECT TAXES**; those which fall in reality on other persons than the immediate subjects of them. They are therefore taxes upon those who finally pay them, and not upon those upon whom they are directly laid. Thus the state exacts custom and excise duties from merchants, upon merchandise, but the consumer, in the price he pays for his articles, refunds this tax to the merchant, so that the last buyer is the one who really pays the tax. There are taxes which appear to be direct, but yet fall indirectly upon others; for instance, the poll tax upon the serfs in Russia. As they are obliged to give every thing, except what they need for their subsistence, to their masters, the latter, of course, obtain so much the less as the poll tax is greater, and thus the tax upon the peasants appears to be an indirect tax upon their masters. Thus almost all direct taxes upon servants are paid by their masters, and therefore a direct tax upon the former is an indirect tax upon the latter. Respecting the opinion that every tax affects those only who derive their income from the soil, see *Physiocratic System*.

**INDORSEMENT OF NEGOTIABLE PAPER.** See *Bills of Exchange*.

**INDOSTAN.** See *Hindoostan*.

**INDRE**; a river in France, which rises about four miles N.N.W. Boussac, in the department of the Creuse; passes by St Sever, La Chatre, Chateauxroux, Chatillon (where it becomes navigable), Loches, Cormery, Amy le Rideau, &c., and joins the Loire at Rigny, between Saumur and Tours.

**INDRE**; a department of France, named from the river Indre. (q. v.) See *Department*.

**INDRE-AND-LOIRE**; a department of France, so called from the rivers Indre (q. v.) and Loire (q. v.) See *Department*.

**INDUCTION**, in logic; a conclusion from the particular to the general. Strict conclusions are made from the general to the particular. The general premise being true, the application to the particular case which is included in it follows with logical certainty. Induction gives only probability. If, for instance, we conclude, from the earth being habitable, that the other planets are so, the conclusion is only probable. Induction rests upon the belief that general laws and rules are expressed in the particular case; but a possibility always remains, that these general laws and rules are not perfectly known. An induction may be perfect or imperfect. To make it perfect, the premises must include all the grounds that can affect the result. If this is not the case, it is imperfect. For instance, every terrestrial animal lives, every aerial animal lives, every aquatic animal lives, every reptile lives; therefore, every animal lives. If we now allow that there exists no animal not included in the four enumerated classes, the induction is perfect.

**INDULGENCE**, in the Roman Catholic system; the remission of sin, which the church has power to grant. (We shall first give the Protestant, and then the Catholic views on this subject.) The visible head of the church, the pope, distributes indulgences in various ways. They are divided into temporary and plenary. The principle of indulgences rests on that of good works; for the Catholic theologians prove the authority of the church to issue indulgences in this way:—many saints and pious men have done more good works, and suffered more than was required for the remission of their sins, and the sum of this surplus constitutes a treasure for the

church, of which the pope has the keys, and is authorized to distribute as much or little as he pleases, in exchange for pious gifts. The historical origin of indulgences is traced to the public penances and the canonical punishments, which the old Christian church imposed on the community, especially on those who did not remain firm unto martyrdom. When ecclesiastic discipline became milder, and the clergy more covetous, it was allowed to commute these punishments into fines, for the benefit of the church. At first, the only source of indulgences was in Rome, and they could be obtained only by going there. At Rome, this treasure of the church was divided among many churches, of which seven principal ones were gifted the most largely by the popes. These churches were termed *stationes indulgentiarum*. One of the richest was the church in the Lateran, on which were bestowed, at its renewed consecration, as many days of indulgence as the drops which fall in a rain continuing three days and three nights. The whole treasure of indulgences of the churches in Rome was accordingly inexhaustible. When the popes were in want of money, and the number of pilgrims who resorted to Rome to obtain the remission of their sins began to decrease, indulgences were put into the hands of the foreign archbishops and bishops; and, finally, agents were sent about, who made them an object of the meanest traffic. During the period of jubilee (see *Jubilee*), the people were taught to believe that the efficacy of indulgences was doubled, and the richest harvests were always reaped at this time. Leo X., famous for his love of splendour, commenced his reign in 1513; and, as the building of St Peter's church had exhausted his finances, he began the sale of indulgences in Germany, without waiting for the jubilee of 1525, in conjunction with the elector of Mentz, who was to receive half the profit; and the latter found an excellent agent for the sale in Tetzel. This flagrant abuse inflamed the zeal of Luther, and the Protestant theologians have always found indulgences one of the most vulnerable points of the Roman Catholic system; and even the Catholic states of Germany represented to the emperor, in 1530, that he ought to prevail upon the pope, to omit sending any more letters of indulgence to Germany, lest the whole Catholic religion should become an object of scorn and mockery. Nevertheless, the right to remit sins was received, in the council of Trent, among the articles of faith.

We shall now proceed to give the Catholic views, as taken from the article *Indulgence*, written by a Catholic, in the German *Conversations-Lexicon*. The penances of the ancient church (see *Penance*) were never so strictly binding as to preclude the presbyters from relaxing them in some degree, in particular instances, where their object seemed more easily attained in some other way. But this never was done, except in single cases, and after the circumstances of the petitioners had been closely examined; nor was the whole punishment ever remitted, but merely a part of it, according as the case of the individual required, and his repentance justified it. The council of Nice, in their 12th canon, require, for such a dispensation, proof of true repentance. In the eleventh century, another kind of indulgences was introduced,—absolution. This was granted to those who undertook some difficult enterprise for the benefit of the church. This was usually bearing arms in her cause, of which the crusades are the most famous example. In the council of Clermont (1095—1096), it was decreed (canon 12), that every one, who, actuated solely by devout zeal, and not by love of glory or by avarice, went on the expedition to Jerusalem for the

deliverance of the holy sepulchre, should receive a full remission of his sins. In later times, this indulgence was extended to those who were not able to go themselves, and sent a champion in their stead. By degrees, the exemption was extended still farther, and soon plenary and partial indulgences were granted to those who gave alms for effecting some good work (e.g. the restoration of a church, &c.), or performed some prescribed labour of piety (the visiting of a church, for instance) at the time of jubilee, which was established by Boniface VIII., in 1300. This gave the death-blow to the public penance of the church. Considerable abuses, however, stole into the system of indulgences, and the scandal became very great. Under pretext of alms for the benefit of good works, indulgences were made the means of indirectly taxing the whole of Christendom. It was proposed several times in the diets of the German empire (e.g. at Nuremberg, in 1466), to make use of them for supplying the expenses of the war against the Turks. The popes, bishops, and civil rulers usually divided the proceeds, though the latter sometimes appropriated them entirely; as, for instance, in 1500, when the government of the empire took possession of the money collected for the pope on the occasion of the jubilee, and allowed only a third part to the legate of the pope, for his subsistence. Under such circumstances, when holy institutions were abused for vile gain, it was natural that wrong notions respecting indulgences and their power, should spring up among the people, and be spread by the preachers employed to distribute them. (See *Tetzl.*) It is a well known fact, that the indulgences proclaimed by Leo X., gave the first spring to the reformation. It was the object of the fathers assembled at Trent, to make a public disavowal of the erroneous doctrines which had been preached by individuals respecting indulgences, that they might not appear to be sanctioned by the church. The council first required (in sess. 24, cap. 8, *De Reformatione*), the restoration of public penance, in the following words: "The holy apostle (Paul to Timothy) ordains, that those who sin publicly, should be publicly rebuked. If, therefore, a crime has been committed publicly, and in the sight of many, so as not to leave any doubt of its giving a bad example to others, a public penance is to be imposed on the guilty person, suited to the crime, that the sight of his repentance may recall those to the right way, whom his example has led astray. The bishop may, however, substitute a private for the public penance, if he thinks it more suitable." Respecting absolution itself, the church has established no dogma, because such dogmas are expressed only in the *canones*, of which there exist none on this subject. She has given only a decree, and this in her last session, which literally says: Since the power of conferring indulgences has been given to the church by Christ, and she has exercised it from the earliest times, the holy council teaches and ordains, that this usage, so beneficial to Christians, and confirmed by the authority of many holy councils, is to be retained in the church; and she inflicts the anathema upon such as either declare indulgences unnecessary, or dispute the power of the church to grant them. It is her wish, however, that in the grant of indulgences, according to the custom long existing in the church, proper limits should be observed, lest the discipline of the church become injuriously relaxed. But as the church desires that the abuses which have crept in, and have given occasion to heretical preachers to heap reproach upon this venerable usage, should be corrected, she ordains by the present decree, that the shameful bartering of indulgences for money, which has been so fruitful a source of abuse, shall be entirely abolished. As the corruptions which have sprung from supersti-

tion, ignorance, irreverence, or from any other cause, cannot here be enumerated and individually censured, on account of the variety of the kinds prevailing in different places and provinces, the synod commands every bishop to search out with diligence the abuses of his own church, and to lay them before the first provincial synod, that they may be branded as errors by the judgment of the other bishops, and be submitted to the authority of the supreme bishop at Rome, whose wisdom will provide for the universal good of the church, that the sacred indulgences may in future be distributed with purity and holiness. The selling of indulgences has accordingly ceased. In regard to the absolution still practised in the church (continues the Catholic writer), the spirit of the church is the same as in ancient times. The old discipline of penance never has been formally abolished. On the contrary, the principle has rather been confirmed by the council of Trent, as has just been shown. The church still commissions her servants to impose penances upon sinners, in proportion to their guilt,—even heavier penances than the ordinary ones. Why, then (he asks), should she not be authorized to remit part of the sentence, if the penitent is found worthy of favour? Whether such remission be deserved by the penitent, is to be judged by those ministers of the church who are in immediate intercourse with them. To make absolution effectual, Bellarmine requires that the end attained should be more agreeable to God than the performance of the penance remitted. The labour itself should be in proportion to its aim. We have seen that there exists no dogma on absolution; it is therefore by no means a doctrine of the church, but it is left to the private views of the individuals, whether and how far the absolution and the idea of purgatory (see *Purgatory*), are connected with each other. It is falsely believed by many Protestants, that absolution is esteemed by the Catholic church equivalent to conversion, and as effectual to remit the punishment of sins. Every popular catechism proves the contrary.

INDUS, or SINDH<sup>\*</sup>; a large river in the western part of Hindoostan, rising on the north of the Himalaya mountains; it flows first north-west, then west, penetrates the chain of mountains in the thirty-sixth parallel, then takes a winding course to the south, and empties by several mouths into the sea of Arabia, between lat. 23° 20' and 24° 40' N. Its chief tributaries are from the east; they were known to the Greeks. One of them is the Behat or Jehum (*Hydaspes*), from Cashmere; it joins the Chenab (*Acetines*), which also receives the Ravy (*Hydrotrus*); below the confluence of the Chenab is that of the Kirah (*Hyphasis*), formed by the junction of the Setledje or Satadrou (*Hesidrus*) and the Beyah. The country traversed by the Indus and its tributaries is called the *Penjab* or *Punjab*. The water of the Indus is wholesome, and resembles that of the Ganges. Its course, including its windings, is estimated at 1700 miles, and is generally W. of S. The Delta of the Indus is about 150 miles in length along the coast, and 115 in depth. The river is navigable, for vessels of 200 tons, to the province of Lahore, a distance of 760 geographical miles. From Attock to the Delta, a distance of about 800 miles, its breadth is generally about a mile, and its depth from two to five fathoms. The tide sets in with great violence. Owing to the barbarous manners of the tribes which inhabit its banks, little commerce takes place on this river. The bed of the Indus is sand, with a small quantity of mud.

\* The name is very ancient. *Indus* is from the Greek, which borrowed it from the Persian. The Persians seem to have derived it from the Indian *Sindhu*, ocean.

**INES DE CASTRO.** Pedro, son of Alphonso IV., king of Portugal, after the death of his wife Constantia (1344), secretly married his mistress, Ines de Castro, who was descended from the royal line of Castile, from which Pedro was also descended on his mother's side. As he steadily rejected all propositions for a new marriage, his secret was suspected, and the envious rivals of the beautiful Ines, were fearful that her brothers and family would gain a complete ascendancy over the future king. The old king was easily blinded by the intrigues of his artful counsellors, Diego Lopes Pacheco, Pedro Coelho, and Alvares Gonsalves. They persuaded him that this marriage would be prejudicial to the interests of his young grandson Ferdinand (the son of Pedro by his deceased wife.) Alphonso asked his son if he was married to Ines. Pedro dared not confess the truth to his father, much less would he comply with the command of the king, to renounce his mistress and unite himself to another. Alphonso again consulted his favourites, and it was resolved to put the unhappy Ines to death. The queen Beatrice, mother of the infant, obtained intelligence of this cruel design, and gave her son notice of it. But Pedro neglected not only this information, but even the warning of the archbishop of Braga, as a rumour intended merely to terrify him. The first time that Pedro left Ines, to be absent several days, on a hunting expedition, the king hastened to Coimbra, where she was living in the convent of St Clara with her children. The arrival of Alphonso filled the unhappy lady with terror; but, suppressing her feelings, she appeared before the king, threw herself with her children at his feet, and begged for mercy with tears. Alphonso, softened by this sight, had not the heart to perpetrate the intended crime. But after he had retired, his evil counsellors succeeded in obliterating the impression which had been made on him, and obtained from him permission to commit the murder which had been resolved on. It was executed that very hour; Ines expired under the daggers of her enemies. She was buried in the convent where she was murdered (1355). Pedro, frantic with grief and rage, took arms against his father, but the queen and the archbishop of Braga succeeded in reconciling the father and son. Pedro obtained many privileges; in return for which, he promised, on oath, not to take vengeance on the murderers. Two years after, king Alphonso died; the three assassins had already left the kingdom, by his advice, and taken refuge in Castile, where Peter the Cruel then reigned, whose tyranny had driven some noble Castilians into Portugal. Pedro agreed to exchange these fugitives for the murderers of Ines. Having delivered them to their master, he received, in return, the persons of Pedro Coelho and Alvares Gonsalves; the third, Pacheco, escaped to Arragon. The two were then tortured in the presence of the king, in order to make them disclose their accomplices; their hearts were torn out, their bodies burnt, and their ashes scattered to the winds (1360). Two years after, he assembled the chief men of the kingdom, at Cataneda, and solemnly declared on oath, that, after the death of his wife Constantia, he had obtained the consent of the pope to his union with Ines de Castro, and that he had been married to her in the presence of the archbishop of Guarda and of an officer of his court, Stephen Lobato. He then went to Coimbra. The archbishop and Lobato confirmed the assertions of the king; and the papal document, to which the king referred, was publicly exhibited. The king caused the body of his beloved Ines to be disinterred, and placed on a throne, adorned with the diadem and royal robes, and required all the nobility of the kingdom to approach and kiss the hem of her gar-

ment, rendering her when dead that homage which she had not received in her life. The body was then carried in a funeral car to Alcobaga. The king, the bishops, the nobles, and knights of the kingdom, followed the carriage on foot; and the whole distance, from Coimbra to Alcobaga, was lined on both sides by many thousands of people, bearing burning torches. In Alcobaga, a splendid monument of white marble was erected, on which was placed her statue, with a royal crown on her head. The history of the unhappy Ines has furnished many poets, of different nations, with materials for tragedies,—Lamothe, count von Soden, &c.; but the Portuguese muse has immortalized her through the lips of Camoens, in whose celebrated *Lusiade*, the history of her love is one of the finest episodes.

**INFALLIBILITY;** exemption from the possibility of error. God, of course, is infallible, because the idea of divinity excludes that of error; Christ was infallible, and, according to the belief of the Greek and Catholic church, and of most Protestant sects, the apostles were also infallible, after the descent of the Holy Ghost. Here, however, the Protestants and Catholics divide. The latter, founding their creed on *tradition* (q.v.) as well as on the *Bible*, maintain that the tradition, that is, the general doctrine and belief, handed down from age to age, and taught by the great body of the pastors, is above the possibility of error; consequently, also, the councils are infallible, because the councils, according to a Catholic writer, "do not make truths or dogmas, as some Protestants maintain, but merely express the belief of the church on certain points in question;" the truth pronounced, therefore, always existed, but had not been previously declared by the church. From several passages in the Bible, the Catholic infers that the above-mentioned tradition and the councils are under the continual guidance and influence of the Holy Ghost: hence the formula so often repeated by the council of Trent, the last general council of the Catholic church—"the holy council lawfully assembled under the guidance of the Holy Ghost." It is clear, that, if the councils are infallible, it is of the utmost importance for the Catholic to know what are lawful councils. This is a point which, as may be easily conceived, has created great discussions in the Catholic church, because the popes claimed the sole right to convocate councils. (See *Council*.) So far all Roman Catholics agree respecting infallibility, namely, that Christ, the apostles, the body of the pastors, the traditions of the church, and the councils, are infallible; but they disagree respecting the infallibility of the pope. The ultramontane theologians maintain that the pope is infallible, whenever he pronounces dogmatically on a point of doctrine, to settle the faith of the whole Catholic church. These theologians are therefore called *infallibilists*. The theologians of the Gallican church do not admit this infallibility. The assembly of the French clergy, in 1682, laid down the maxim, "that in questions of faith, the sovereign pontiff has the chief part, and that his decrees concern the whole church; but that his judgment is not irreformable, until it be confirmed by the acquiescence of the church." Bossuet, in his *Defensio Declarat. Cleri Gallic.*, 2d part, 4. 12 seq. has treated this point at length. He maintains, that the pope is by no means infallible, and that a papal decision is not to be considered infallible until the church acquiesces in it, which, he admits, may be done, in general, silently.

In politics, the word *infallible* is used in a different sense. The position that any political person, or body, is infallible, only means, that there is no appeal from such person or body. When the English public law declares that the king can do no

wrong, every one knows that this is merely a political fiction. But the genuine supporters of divine right believe in a somewhat more real political infallibility of kings.

INFANT, in law. By the English, and generally by the American, and so by the French law, persons come to majority at the age of twenty-one years, until which time they are called in law *infants*, and are under guardianship or tutelage. Infants cannot, in general, bind themselves by contracts, as they are supposed not to have sufficient discretion for this purpose. But this is their privilege, and their contracts are accordingly held in general not to be void, but only voidable at their election; and they may elect to avoid their contracts during their minority, but they cannot confirm them so as to be bound by them, until their majority. Infants may possess property, but it must be under the management and control of a guardian. They have not the right of citizens as to voting, and discharging other political functions. But in regard to crimes and punishments, and trespasses and private wrongs, their conduct is regulated by the same laws as that of the other members of the community, in case of their being of sufficient age and discretion to understand their duties and obligations. And for this purpose no general limit can be assigned, as some children are much more intelligent than others of the same age; and it will again depend, in some degree, upon the nature of the offence committed, or the wrong done, whether a child of any given age can be considered legally guilty of it, since some offences and wrongs can be more easily understood to be such than others. The law, in general, has a tender regard to youth, and does not permit them to be convicted and punished for offences and trespasses, unless it appears clearly that they have sufficient knowledge and discretion to distinguish them to be such.

There are exceptions to the incapacities of minors as to contracting, and these exceptions are made for their benefit. Thus an infant not sufficiently furnished with necessary clothes, food, or instruction, by his parent or guardian, and not being under the immediate superintendence of the parent or guardian, may make a valid contract, in respect to those subjects, and such contract may be enforced against him. Another exception to the general incapacity of infants to contract, relates to the contract of marriage, which, by the law of England and the United States of America, may be made by a male at the age of fourteen, and by a female at that of twelve. The French code fixes the age for making a valid marriage contract, in the case of the male, at eighteen, and in that of the female at fifteen. And as the law gives validity to the principal contract, the prevalent doctrine, though subject to some doubt as to the extent of its application, is, that all contracts collateral and incidental to that of marriage, such as making marriage settlements by the husband, and accepting them instead of dower by the wife, are equally binding on both of the parties, being of age to contract marriage, and, accordingly, not subject to be revoked either before or after coming to the age of majority. If, however, one party be under the age at which a contract of marriage may be made, he or she may, on arriving at such an age, either ratify or annul any such contract previously made. The jurisdiction in respect to infants is generally vested in either probate or orphans' courts. These courts appoint guardians to take charge of the property of infants, and, in case of the decease of the father, to take charge of their persons; but, during the life of the father, he has the guardianship and control of the persons of his sons until they are twenty-one years of age, and of his daughters until they are either

eighteen or twenty-one. At a certain age, however, that is, twelve or fourteen, the child, in case of the decease of the father, may choose his own guardian, who, being approved by the proper judge, is appointed accordingly. See *Infants*.

INFANT SCHOOLS. See *Schools*.

INFANTE, or INFANT (a word derived from the Latin, signifying *child*); the title given, particularly in Spain and Portugal, to the princes of the royal house, the eldest being also called *el principe*. The princesses at these courts are called *infantas*, the eldest also *la princesa*.

INFANTRY.\* If cavalry (q. v.) are to be called *l'arme du moment*, the great work of the battle is to be performed by the infantry, which composes the greatest part of an army, and is, in point of character, the most important part, because it can be used every where—in mountains, on plains, in woods, on rivers, and at sea, in the redoubt, in the breach, in cities, and fields, and, depending only on itself, has a great advantage over the two other classes of troops, who, depending, in a great measure, for their efficiency on the strength and the will of brutes, are far less fitted to endure deprivation, and a noxious climate, to contend with the snows of Russia, or the deserts of Egypt. The infantry are pre-eminently the moral power of armies; and on no class of troops has a general, who knows how to act on his soldiers, such influence. Foot soldiers were armed, in old times, with a spear, sometimes with a sword, arrow, lance, and sling; at present, with a gun and bayonet, which is generally accompanied with a sword. Sometimes, but rarely, they are armed with pikes. Some foot soldiers, in most armies, have rifles, generally so constructed that the rifleman may put his short sword on the rifle, to be used as a bayonet, though this has proved of no great service. The sword given to foot soldiers, in almost all armies, is of but little advantage, and is generally intended principally for ornament, to complete the soldierlike look, rather than to be used in fighting. It serves, however, for cutting branches, to be used in cooking and building huts; but swords might be given to foot soldiers, similar to the sailors' cutlasses, which would answer all these purposes, and also the chief end—to fight. (See *Cutlass*.) They ought always to have a sufficient guard for the hand. The foot soldier has no defensive covering, or very little. The greatest is his mantle, rolled up, and worn on one shoulder by the Prussian and Russian troops. The helmet or cap protects the head, and epaulettes (q. v.) are sometimes used to protect the shoulders. The thick cue, with wire in it, has sometimes been considered a defence to the neck. Infantry is divided into light infantry and that of the line. The latter forms the great mass, which is intended to fight in line, to decide attacks by the bayonet, to make assaults, and is itself again divided into grenadiers (q. v.) and musketeers. The light infantry is particularly intended to serve in the outposts, to act as sharpshooters, to make bold expeditions, and harass and disquiet the enemy. It includes the riflemen. The light infantry form from the thirtieth to the sixtieth part of an army. The character of military operations, however, has changed of late so much, that,

\* Though the word is immediately derived from the Italian *infanteria* and *fanteria*, it is primarily of German origin. We find still, in the dialect of Lower Saxony, *Fent* and *Fent*, signifying a young, unmarried man, and, in a more extended meaning, a servant, a soldier on foot. The Icelandic *fent*, Italian *fente*, Danish *fent*, Swedish *fente*, have the same meaning with the Low-Saxon *Fent*, and are, no doubt, connected with the Latin *infans*. With the prefixed sibilant, this root became, in Anglo-Saxon, *swin*, in English *swine*, in Danish *svin* (a youth employed in country service, a young lover).

in a good army, it is necessary that the infantry of the line should take part readily in the light service, and the light infantry be ready to fight in the line, from which the riflemen only are excepted. These are only used as sharpshooters. In some armies, there are, besides the riflemen, whole regiments of light infantry; in others, as in the Prussian army, each regiment has two battalions of infantry of the line, and one battalion of light infantry; in others, as in the French, each battalion has its grenadiers and *tirailleurs* (sharpshooters). Infantry is divided into battalions (q. v.), these into companies, these into platoons. Several battalions, two or three, sometimes four or five, form a regiment. The tactics of infantry admit three different modes of arranging this species of troops in battle—1. in line, when they are drawn up in line two or three men deep, an order very rarely, if ever, used at present; 2. in column, when several lines, three or two men deep, are drawn up one behind the other (See *Column*, in *Tactics*, and *Square*); 3. in dispersed order. (See *Sharpshooters*.) The excellence of infantry depends on their good order in advancing and retreating, perfect acquaintance with their exercises and duties, in a just application of their fire, and great calmness both in assaulting and when assaulted in the square, which is acquired by experience. As long as the infantry remain calm, the general need not lose hope; but all is to be feared when they are disordered, whether through ardour or fear.

In countries affording horses, men always prefer, in the early periods of society, to fight on horseback, and civilization only gives more importance to infantry. Where foot soldiers exist, at this early period, together with cavalry, they are considered of inferior consequence. The Hebrew army, however, consisted, for a long time, of infantry only. (See *Cavalry*.) The Egyptians, likewise, seem to have used cavalry little. With the Asiatics, besides the use of infantry and cavalry, princes and noblemen fought on chariots. The infantry was the part least esteemed, and, with the Persians, consisted of the heavy-armed, the slingers, and archers. Probably this was one reason of the victories of the Greeks over the Persians, as they had cultivated infantry more, and had given up the chariots, described by Homer as common in the Trojan war. Even their kings and generals fought on foot. They had both heavy and light infantry. The Greeks were conquered, in their turn, by an improved form of infantry, the columns, of Philip of Macedon, which also enabled his son Alexander to conquer the Persians. With the Romans, infantry was the strength of the armies. Their legions, consisting mostly of infantry, conquered the world. With the ancient Germans and Gauls, also, infantry was considered very important; but when, in the great migration of nations, the Huns, and other Mongolic tribes, arrived in Europe, on small and fleet horses, and carried victory with them, spreading the terror of their arms far and wide, and when the Franks in Northern Spain became acquainted with the Moors, who came from Arabia, and the plateau of Asia, on beautiful horses, cavalry was considered as more important. When the feudal system was developed, the horse, of course, was more agreeable to the adventurous knight, than the foot service. The crusades, where the Europeans were obliged to fight with the fine cavalry of the Seljooks, favoured this tendency still more. Infantry fell into total disrepute, and consisted of the poorer people, who cared little in whose service they fought, in those times of violence and oppression, when a change of rulers made no change in their sufferings; and no reliance could be placed upon them. Among those people who were not in feudal bondage, and

fought for the defence of their own liberty, infantry maintained its old importance, as with the Swiss, on several occasions in the fourteenth and fifteenth century; and the penetrating Machiavelli, who burned to free his country from its numberless foreign and native tyrants, saw the great value of infantry, and urged its establishment upon a respectable footing. The invention of gunpowder changed the whole art of war, and brought infantry again into repute. (See *Army*.) The Swedish infantry, in the thirty years' war, was excellent. The arrangement became, in the course of time, more judicious, and all unnecessary manœuvring was avoided. The Austrians, at this time, employed soldiers from their Turkish frontiers—the Croats and Pandours, semi-savages—as a sort of irregular light infantry; and other armies had troops of a similar character; but they were so rude and disorganised, because their warfare was little better than legalised robbery, that Gustavus Adolphus would not admit them into his forces; but Frederic the Great again established free corps (q. v.) during the seven years' war. Infantry remained without much change in the eighteenth century. Prince Leopold of Dessau, during this time, first introduced, in the Prussian army, the iron ramrod, the lock-step, and several other improvements. The bayonet having been invented already in the middle of the seventeenth century, came more and more into use, and enabled the squares to resist the cavalry; but a great change in the use of infantry took place towards the end of the eighteenth century, when, in the American war of independence, the people, being obliged to contend, without discipline, against well trained troops, adopted the irregular mode of fighting, protected by trees or other objects, being, at the same time, mostly skilful marksmen. The efficiency of this method of fighting was evident; and when, in 1791, the French revolutionary war began, the French sent swarms of *tirailleurs* against the allies, and injured the latter exceedingly. In the wars from 1791 to 1802, the French greatly improved this way of fighting, which, in the interval of peace that followed, was reduced to a system, the consequences of which were seen in 1805, 1806, and 1807, against the Austrians, Prussians, and Russians. These nations, after the disasters which they suffered, adopted the same system, as well as the greater use of columns, particularly as the ordinary mode of arranging the troops before they came into the fire. Under equal circumstances, well trained infantry is almost uniformly successful against any other kind of troops.

INFERIE, in Roman antiquities; sacrifices offered to the infernal deities for the souls of the departed. Some writers have thought that they are the origin of the exequies of the Catholic church.

INFÉRNO (Italian for *hell*); the name of the first part of Dante's grand poem. See *Dante*.

INFINITESIMALS. See *Calculus*.

INFINITIVE; the indefinite mode, in which the verb is represented without a subject. As the verb expresses an action, or a state, it generally belongs to a subject whose action or state is expressed; but if we wish to express the mere idea of this action or state, we use the infinitive, which therefore, in many languages, is employed without further change, as a substantive—for instance, in Greek and German—only preceded by the neuter article; but, as the verb expresses an action or state, under certain conditions of time, the infinitive can also express the action or state in the present, past or future, though these conditions are not expressed in all languages by peculiar forms; nay, some languages have not even a peculiar form for the infinitive present, and must express it by some grammatical contrivance, as is the case in English. See *Verb*.

INFLAMMATION OF THE INTESTINES. See *Enteritis*.

INFLXION, POINT OF, in the theory of curves; that point in which the direction of the curve changes from concavity to convexity, and *vice versa*. It is particularly called *punctum inflexionis*, at the first turning, and *punctum regressionis* when the curve returns. These points are of much interest in the theory of the functions.

INFLUENZA (Italian, *influence*); a term used in medicine to denote an epidemic catarrh which has, at various times, spread more rapidly and extensively than any other disorder. It has seldom occurred in any country of Europe, without appearing successively in every other part of it. It has sometimes apparently traversed the whole of the Eastern continent, and, in some instances, has been transferred to America, and has spread over this continent likewise. The French call it *la grippe*. In all the known instances of its occurrence, from the 14th century, its phenomena have been pretty uniform, and have differed little, except in severity, from those of the common febrile catarrh. In 1802, such an influenza attracted universal attention. In February, it set out from the frontiers of China, traversed all Russia, extended along the Baltic, to Poland and Denmark; reached Germany and Holland in April and May, and France and Spain in June. It could even be followed to Gibraltar. No sex, age, or state of health was exempted. It showed itself chiefly as a severe cold, attended with a catarrhal fever of a more or less inflammatory or bilious character. Generally, it passed over within a few days, yet, in some places, it gave a check to business. Few persons died of it, except those who were afflicted at the same time with other diseases, but almost every one was attacked. G. F. Meier, a German physician, attempted to prove that Europe suffered periodically from the influenza. He maintained that, during the greater part of the period which had elapsed since 1712, this epidemic had visited Europe, at intervals of about twenty years, and still more frequently in the early part of the period. Accordingly, he prophesied a new one for 1820, which, however, did not happen.

INFORMER. To encourage the apprehending of certain felons, divers English statutes of 1692, 1694, 1699, 1707, 1720, 1741, and 1742, granted rewards of from ten to fifty pounds sterling, to such as should prosecute to conviction highwaymen, counterfeiters, and thieves. These acts were passed at the time of the troubles in Great Britain, occasioned by the risings of the Jacobites, when, with the increase of political criminals, the number of private offenders was thought to be increasing also. By the law of 1699, besides the forty pounds, an immunity from all parish officers (overseer of the poor, churchwarden, &c.) was allowed to any person who should prosecute to conviction a felon guilty of burglary, horse-stealing, &c. The *Tyburn tickets* (as the certificates of exemption were called) could be sold, as the first was of no use to a man who received a second, and were actually sold in large cities, like Manchester, at high prices (from 250 to 300 pounds sterling.) The amount of the rewards (without including the Tyburn tickets), in the forty counties of England, for 1798, was £7700, and, in 1813, it had risen to £18,000. The abuses which originated from this system were horrible. The police officers made a trade of it, by seducing poor, ignorant persons, chiefly foreigners, to crimes (principally the issuing of counterfeit money), in order to gain the reward by prosecuting them for the offence. A certain M'Daniel confessed (1756) that he had caused, by his testimony, seventy men to be condemned to death. He was brought to

the bar with two others, but the people, fearing they were to be acquitted, treated them with such violence, that they were killed on the spot. In 1792, a similar case happened, in which twenty men had become the victims of an informer. A more recent case, in 1817, excited greater indignation. Four police officers, who had entered into a conspiracy against the life of poor men, were condemned to death, but, on account of some judicial formalities, were released by the twelve judges (the united members of the three chief tribunals in Westminster hall), and escaped without punishment. They had induced several poor women to pass counterfeit money, and seized them in the act. In other cases, such men endeavoured to change a small offence into a capital crime; for instance, if one had stolen the work-bag of another, they swore that it had been tied with a string or ribbon to the arm, and torn from it by violence, by which theft was transformed into robbery, and, instead of imprisonment, the punishment was death, and the informer received the price of blood (£50). A revolting case of this kind happened (1817) when two soldiers, who were wrestling with another, in sport, for a wager of one shilling, were condemned for robbery by the artifice of a police officer, and escaped with the greatest difficulty from an undeserved punishment. Small offences were kept secret by the police officers, and the perpetrators watched, until, as they termed it, they weighed forty pounds sterling. For prosecution to conviction of any person attempting to pass counterfeit bank notes (which was, until lately, a capital crime), the bank paid £30, and for the prosecution of a person issuing counterfeit coin, £1. Several persons became the victims of this provision. The police officers very well knew the counterfeiters, and those who made it a trade to induce women and children to change their false notes, and deliver them into the hands of the police; but they spared the true authors of the crime, as good customers, and denounced the poor wretches employed by them, who were condemned by the jury upon the slightest suspicion, and executed without mercy. Alderman Wood asserted, in parliament, that, in the year 1818, at a visitation of the prison, he had found thirteen men, mostly Irishmen and Germans, who had received counterfeit money from others, to buy bread, had been seized in the act and condemned, without any regard to their assertions that they were ignorant of the character of the money. These rewards were abolished in 1818, by an act of parliament (58 George III., c. 70), but the abuse in respect to the bank notes remained as before.

INFULA was, with the Romans, the wide, white woollen ornament of the head of priests, vestals, and even of animals offered for sacrifice, the hiding of the head being considered a mark of humiliation. At later periods, the imperial governors wore the *infula* as a sign of dignity, and, as such, it was adopted, in the seventh century, by the bishops of the Catholic church, who continue to wear it on solemn occasions, and have it, instead of a crown or helmet, in their coat of arms. It consists of two pieces, turning upward, of a pointed form, one before and one behind, so that in the middle there is a hollow. They are of pasteboard, or tin, and covered with white silk, the one in front being ornamented with a cross. The bishops of the church of England have an *infula* still in their coat of arms, but never wear it on the head. With them, however, it is generally called *mitre*, from *mitra*, which, according to Von Hamme, originally meant the globular part of the head-dress of Persian kings, indicating, originally, the ball of the sun, which the Persian kings wore on the crown, and the Egyptian on the head. *Mithra* was the genius of the sun with the Persians. See *Mithra*.

INGE; a Saxon word signifying *field*, appearing in many German geographical names, as *Thüringen*, *Thüngen*, *Zophingen*, &c.; also in Dutch names, as *lingen*.

INGENHOUS, John, a naturalist, born at Breda, in 1730, practised physic in his native city, and afterwards went to London, where he was well received by Pringle, the president of the royal society. The empress Maria Theresa, having lost two children by the small-pox, ordered her ambassador at London to send her an English physician, to vaccinate the others. Pringle recommended Ingenhous, who received honours and presents, at Vienna, for the easy operation, which was not then much practised. He then travelled, and finally settled near London, where he died in 1799. He was the author of several treatises on subjects of natural history, which he enriched by several important discoveries.

INGOT, in the arts, is a small bar of metal made of a certain form and size, by casting it in moulds. The term is chiefly applied to the small bars of gold and silver, intended either for coining or exportation to foreign countries.

INGRIA; a former province of Sweden, on the bay of Finland. It belonged, as early as the thirteenth century, to Russia, was inhabited by the Ingrians or Ishorians, and received its name from the river Iuger, the former name for Ishora, when the Swedes took possession of it in 1617. In 1700, the Russians reconquered it. It forms, at present, a part of the government of St Petersburg, in which the capital, St Petersburg, is situated.

INGULPHUS, abbot of Croyland, and author of the history of that abbey, was born in London about 1060. He received his early education at Westminster, and afterwards went to Oxford, where he applied to the study of Aristotle, and, as he says, "clothed himself down to the heel in the first and second rhetoric of Tully." In the year 1051, William, duke of Normandy, then a visitor at the court of Edward the Confessor, made Ingulphus, then of the age of twenty-one, his secretary. He accompanied the duke to Normandy, afterwards went on a pilgrimage to the Holy Land, and, upon his return, entered into the order of the Benedictines, at the abbey of Fontenelle, in Normandy, of which he became prior. On the acquirement of the crown of England by William, Ingulphus was created abbot of the rich monastery of Croyland. He died in 1109. His history of the monastery of Croyland is interspersed with many particulars of the English kings. It was published by Sir Henry Savile, in 1596, among the *Scriptores post Bedam*, and has been reprinted both at Frankfurt and at Oxford, the latter of these editions, dated 1684, being the most complete. The history of Croyland comprises from 664 to 1091.

INHERITANCE. See *Descent and Estate*.

INJECTIONS belong partly to surgery and partly to anatomy. In surgery, fluids, different, according to the different effects desired to be produced, are thrown, by means of a small syringe, into the natural cavities of the body, or those occasioned by disease, partly to remove unhealthy matter, and partly to bring the remedy immediately to the seat of the disorder, and thus effect a cure. Wounds and sores are usually cleansed in this way, when they extend far below the skin, for an excitement and cure are produced by the same method. Cato the Censor had one applied to himself when he suffered from a *fracture*. In diseases of the nose and the cavities connected with it, in those which have their seat in the neck, in disorders of the ears, the bladder, and urethra, the uterus and vagina, and for the radical cure of hydrocele, injections are often used, and with important advantages. Pure warm water is injected,

with the highest success, for the removal of pus, blood, or even foreign bodies. Sometimes astringent medicines, to restrain excessive evacuations, sometimes stimulating ones, to excite inflammation, as in hydrocele, or even to increase and improve evacuations, sometimes soothing medicaments, to mitigate pain, &c., are added to the water. In diseases of the throat which hinder the patient from swallowing, and thus tend to produce death by starvation, nourishing fluids are injected into the stomach. The blood of beasts, or of men, has been sometimes injected into the veins, which is called *transfusion*. In the same way, medicines are introduced immediately to the blood; for instance, tartar emetic to excite vomiting, if a foreign body is fixed in the throat so firmly as to restrain the patient from swallowing, and can neither be moved up nor down. According to the place where the injection is to be made, the instrument must be either longer or shorter, a straight or a curved tube. The size is regulated by the quantity of the liquid to be injected, and the force which is to be applied. Anatomists inject into the vessels of bodies various coloured fluids, which are liquid when hot, and coagulate when cold, to make the smaller ones visible. Thus the arteries, veins, and lymphatic vessels are injected. Anatomy has carried this art so far as to make very minute vessels visible to the naked eye.

INJUNCTION is a prohibitory writ, issuing by the order of a court of equity, restraining a person from doing some act which appears to be against equity, and the commission of which is not punishable by the criminal law. An injunction may be obtained to stay waste, as where a tenant for life, or years, is proceeding to cut down timber which he has no right to cut; to prevent vexatious litigation in the courts of common law, as where a man persists in bringing actions to recover an estate, notwithstanding repeated failures; to enable a man to make a just defence, which he could not make at common law, as where the legal defence to a claim rests exclusively, or to a great degree, in the knowledge of the party advancing the claim; to prevent infringement of a copyright, or a patent, &c.

INJURIA (*Latin*), in law; properly, every act by which some one suffers unlawfully. In the Roman law, the obligations arising from such violations formed a class by themselves, which were regulated by the *lex Aquilia*, so called because the tribune Aquilius (in the sixth century, between the destruction of Carthage and Corinth, and during the beginning of the civil wars) had caused the law to be enacted. At a later period, the right to ask legal redress was also extended to a mere violation of the honour of a person; and, in the laws of modern nations, this has been retained, though with a great variety of views. In the middle ages, the duel was authorized by law; and, when the laws took from individuals the right of redressing their own wrongs, it was deemed necessary to offer some other mode of redressing injuries to honour, which had been one of the most fruitful sources of duels. The common law of England punishes injuries to honour only when they amount to malicious attempts to blacken a man's reputation (see *Libel*, and *Slander*); but according to the Prussian code, a person may be sued for having used insulting language, or even insulting gestures, on the mere ground of violation of honour, and not of any other damage inflicted thereby. But, of late, the right has been considerably restricted; for instance, the complaint must be entered within a short period fixed by law, &c. According to the laws of the German states, the petition of the complainant may be to have the *amende honorable* made him, as by an apology for the insult, &c., or to have

the offender punished. Legislation and adjudication on injuries to honour are matters of much delicacy, beyond the limits of the English law, which makes reparation only in cases where the offence has produced, or is directly calculated to produce injury, to a man, in his character or business.

**INK, WRITING.** This material can be prepared of various colours, but black is the most common. Doctor Lewis gives the following receipt:—In three pints of white wine, or vinegar, let three ounces of gall-nuts, one ounce powdered logwood, and one ounce green vitriol be steeped half an hour; then add one ounce and a half gum Arabic, and, when the gum is dissolved, pass the whole mixture through a hair sieve. Van Mons recommended the following preparation:—Let four ounces gall-nuts, two ounces and a half sulphate of iron, calcined to whiteness, and two pints water, stand in a cool place 24 hours; then add one ounce and a quarter gum Arabic, and keep it in a vessel open, or slightly stopped with paper. Another recipe is this:—Take one pound gall-nuts, six ounces gum Arabic, six ounces sulphate of iron, and four pints beer, or water; the gall-nuts are broken, and stand as an infusion twenty-four hours; then coarsely-pounded gum is added, and suffered to dissolve; lastly, a quantity of vitriol is introduced, and the whole passed through a hair sieve. It is generally observed, that unboiled inks are less likely to fade than others. A good red ink is obtained as follows:—A quarter of a pound of the best logwood is boiled with an ounce of pounded alum, and the same quantity of cream of tartar, with half the quantity of water, and, while the preparation is still warm, sugar and good gum Arabic, of each one ounce, are dissolved in it. Solutions of indigo with pieces of alumina, and mixed with gum, form a blue ink. Green ink is obtained from verdigris, distilled with vinegar, and mixed with a little gum. Saffron, alum, and gum water, form a yellow.—It is not well ascertained how soon the present kind of writing ink came into use. It has certainly been employed for many centuries in most European countries; but the ancient Roman inks were, for the most part, of a totally different composition, being made of some vegetable carbonaceous matter, like lamp-black, diffused in a liquor. The Chinese, and many of the inks used by the Oriental nations, are still of this kind. Sometimes the ink of very old writings is so much faded by time as to be illegible. Doctor Blagden (*Philosophical Transactions*, vol. lxxvii.), in his experiments on this subject, found that, in most of these, the colour might be restored, or, rather, a new body of colour given, by pencilling them over with a solution of prussiate of potash, and then with a dilute acid, either sulphuric or muriatic; or else, *vice versa*, first with the acid, and then with the prussiate. The acid dissolves the oxide of iron of the faded ink, and the prussiate precipitates it again of a blue colour, which restores the legibility of the writing. If this be done neatly, and blotting paper laid over the letters as fast as they become visible, their form will be retained very distinctly. Pencilling over the letters with an infusion of galls also restores the blackness, to a certain degree, but not so speedily nor completely.

**China or Indian Ink.** The well known and much admired Indian, or China ink, is brought over in small oblong cakes, which readily become diffused in water by rubbing, and the blackness remains suspended in it for a considerable time, owing to the extreme subtilty of division of the substance that gives the colour, and the intimacy with which it is united to the mucilaginous matter that keeps it suspended. Indian ink does, however, deposit the whole of its colour by standing, when it is diffused in a considerable quantity of water. Doctor Lewis, on

examining this substance, found that the ink consisted of a black sediment, totally insoluble in water, which appeared to be of the nature of the finest lamp-black, and of another substance soluble in water, and which putrified by keeping, and, when evaporated, left a tenacious jelly, exactly like gum, or isinglass. It appears, probable, therefore, that a consists of nothing more than these two ingredients, and probably may be imitated with perfect accuracy by using a very fine jelly, like isinglass, or gum, and the finest lamp-black, and incorporating them thoroughly. The finest lamp-black known is made from ivory shavings, and thence called *ivory black*.

**Printers' Ink.** This is a very singular composition, partaking much of the nature of an oil varnish, but differing from it in the quality of adhering firmly to moistened paper, and in being, to a considerable degree, soluble in soap-water. It is, when used by the printers, of the consistence of rather thick jelly, so that it may be distributed over the types readily and thinly, when applied by rollers made of a composition of glue and molasses; and it dries very speedily on the paper, without running through to the other side, or passing the limits of the letter. It is made of nut-oil, boiled, and afterwards mixed with lamp-black, of which about two ounces and a half are sufficient for sixteen ounces of the prepared oil. Other additions are made by ink-makers, of which the most important is generally understood to be a little fine indigo in powder, to improve the beauty of the colour. Red printers' ink is made by adding to the varnish about half its weight of vermilion. A little carmine also improves the colour. (*Encyclopædie, Arts et Mètièrs*, vol. iii. page 518.)

**Coloured Inks.** Few of these are used, except red ink. The preparation of these is very simple, consisting either of decoctions of the different colouring or dyeing materials in water, and thickened with gum Arabic, or of coloured metallic oxides, or insoluble powders, merely diffused in gum-water. The proportion of gum Arabic to be used may be the same as for black writing ink. All that applies to the fixed or fugitive nature of the several articles used in dyeing, may be applied, in general, to the use of the same substance as inks. Most of the common water-colour cakes, diffused in water, will make sufficiently good coloured inks for most purposes.

**Sympathetic Inks;** liquids without any observable colour; any thing may be written with them invisible, and made visible at will by certain means. Even Ovid informed maidens who were closely watched, that they might write to their lovers whatever they pleased with fresh milk, and when dry sprinkle over it coal-dust, or soot. In modern times, chemistry has taught the preparation of many improved inks of this nature:—Form a solution of green vitriol in water, and add a little alum, to prevent the yellow iron precipitate from sinking, which always rises in case the acid does not prevail; this solution forms a sympathetic ink, which appears extremely black when it is moistened with a saturated infusion of gall-nuts. A sympathetic ink may likewise be formed from common black ink. For this purpose, the colour must be destroyed by a mixture of nitric acid. Any thing written with it becomes visible on moistening it with a solution of some volatile alkali. The famous ink, invisible in the cold, and visible at a moderate temperature, may be prepared without much difficulty. (See *Cobalt*.) Any writing with this ink is invisible; but, on the application of a certain degree of heat, it becomes a beautiful greenish blue. As soon as it cools again, the colour vanishes; and thus, by alternately heating and cooling it, the writing can be made visible or invisible. Care must be taken not to heat it more than is required to make

R. plain, for otherwise it always continues visible. With this sympathetic ink landscapes may be drawn, in which the trees and the earth lose their verdant appearance in the winter, but may be changed again into a spring landscape, at will, by exposing them to a gentle heat. This has been already tried on screens.

INLAND NAVIGATION. See *Canals*.

INN, a river in the south of Germany, rises in the Grisons, flows through Tyrol and Bavaria, and empties into the Danube at Passau. It is navigable from Telf. Inspruck (q. v.) is situated on this river.

INNATE IDEAS: certain primary notions, or impressions, supposed by many philosophers to be given to the mind of man when it first receives its being, and to be brought into the world with it. Their existence has afforded ground for much dispute among philosophers.

INNOCENT: the name of thirteen popes, among whom are the following:—

*Innocent I.*, saint, a native of Albano, succeeded Anastasius I., as bishop of Rome, in 402. He was in great favour with the emperor Honorius, and induced him to take severe measures against the Donatists. He supported St Chrysostom (q. v.), and renounced the communion with the Eastern churches, on account of their treatment of that eminent man. In 408, he was sent to obtain terms of peace from Alaric, but without success, in consequence of the opposition of the pretorian prefect Jovius. (q. v.) Rome was taken and pillaged, in 410, while Innocent was still in Ravenna. He condemned the Pelagians as heretics, in a letter to the African churches, but excited their opposition by his arrogant tone. He died in 417; according to some, in 416. He is one of the most distinguished among the saints; his day is July 28. His decrees (in the Collection of Dionysius Exiguus) and letters (most complete in Schœnemann's *Pontif. Rom. Epist. genuinæ*) prove his zeal for the establishment of the Roman supremacy; but part of them are considered, by many critics, spurious. Zosimus was his successor.

*Innocent II.*, a Roman of noble birth, elected pope, in 1130, by a part of the cardinals, whilst the others elected Peter of Leon, who took the name of *Anacletus*. Innocent fled to France, where, by the mediation of Peter of Clairvaux, he was acknowledged by the council of Étampes, by Louis VI., and, soon after, by Henry II. of England, also by the German king Lothaire, who conducted him, in 1138, to Rome, where he occupied the Lateran, whilst Anacletus occupied the castle of Crescentius, the church of St Peter, and a large part of the city. Innocent was soon obliged to retire to Pisa, and, though the emperor reinstated him, in 1137, Anacletus maintained himself until his death, in 1138. Having prevailed against another anti-pope, he held the second oecumenical council in the Lateran, where nearly 1000 bishops condemned Arnold of Brescia and his heresy, declared all the decrees of Anacletus null, and excommunicated Roger of Sicily, who had supported the latter. But Roger waged war against the pope, made him prisoner, and obliged Innocent to acknowledge him as king, absolve him from excommunication, and invest him and his heirs with Apulia, Calabria, and Capua. Towards the end of his pontificate, he put France under an interdict, and had to struggle with constant disturbances in Rome and Tivoli. He died in 1143. Celestine II. succeeded him. His letters are to be found in Baluze, Martène, and others.

*Innocent III.*, Lothaire, count of Segni, born at Anagni, in 1161, studied in Rome, Padua, and Bologna. On the death of Celestine III. (1198) cardinal John of Salerno declined the pontificate, which

had been offered to him, and proposed Lothaire, who was unanimously elected, at the age of thirty-seven. The death of the emperor Henry VI., in 1197, had thrown the imperial affairs in Italy into the greatest confusion. Innocent, in the vigour of manhood, endowed by nature with all the talents of a ruler, possessed of an erudition uncommon at that time, and favoured by circumstances, was better qualified than any of his predecessors to elevate the papal power, which he considered as the source of all secular power. By his clemency and prudence, he gained over the inhabitants of Rome, obliged the imperial prefect to take the oath of allegiance to him, and directed his attention to every quarter where he believed, or pretended to believe, that a papal claim of property, or of feudal rights, existed. From the imperial seneschal, duke Marquard of Romagna, he required homage for the Mark of Ancona, and, on his refusal to comply, took possession of the Mark, with the assistance of the inhabitants, who were dissatisfied with the imperial government, and excommunicated Marquard; obliged the duke Conrad of Spoleto to resign that duchy, and would also have taken Ravenna, if the archbishop had not prevented him. He concluded treaties with many cities of Tuscany for the mutual protection of their liberties and those of the church. Thus he soon obtained possession of the ecclesiastical states, in their widest extent. He conferred Naples on the widowed empress Constantia and her minor son, afterwards the emperor Frederic II., after having abolished all the privileges conceded by Adrian IV., in 1156, assumed the guardianship of the young prince, after the decease of the empress, and frustrated all the machinations of Marquard to deprive him of his inheritance. In Germany, Innocent favoured the election of Otho IV. against Philip of Suabia, crowned him, in 1209, at Rome, but soon became involved in disputes with him, on account of his violations of the promises which he had made to the church. He excommunicated Philip Augustus, king of France, laid the kingdom under an interdict, in 1200, because Philip had repudiated his wife, Ingeburge, and obliged the king to submit. He was still more decided in his treatment of John (q. v.), king of England, who refused to confirm the election of Stephen Langton as archbishop of Canterbury. Innocent laid the kingdom under an interdict, and, in 1212, formally deposed him, and instigated the king of France to attack England. John was finally obliged to submit, resigned his territories to Rome, and received them as a papal fief, from Innocent, from whom he was unable to obtain absolution until he had paid large sums of money. Almost all Christendom was now subject to the pope; two crusades were undertaken at his order, and his influence extended even to Constantinople. Innocent was one of the greatest popes and rulers; he acted in accordance with the principles laid down in his writings; he enforced purity of morals in the clergy, and was himself irreproachable in private life; yet the cruel persecution of the Albigenses in the south of France, which he encouraged, though without approving of all its rigours, and the inquisitorial tribunals established by him in 1198, from which the inquisition itself originated, are stains on his pontificate, but partially effaced by a consideration of the spirit of the times and the disordered state of the Christian world. It may be said of his rule, as of that of Gregory VII., whom he most resembles, that, in those times, the power of the pope was salutary, as a bond of union for Europe, in which the still firmer bond of a common civilisation and knowledge did not, as at present, exist. His attacks on the secular power are to be considered as the struggle between the ecclesiastical and secular

power, which was natural and necessary in the development of European civilization. If he had not subdued the monarchs, they would have crushed the papal power. In 1215, he held a council of more than 1300 archbishops, bishops, prelates, and ambassadors of European princes, by which transubstantiation in the Lord's supper and auricular confession were established as dogmas, Frederic II. was acknowledged as German emperor, and the Franciscan and Dominican orders were confirmed. Innocent died soon after, on the 16th of July, 1216. Some of his works on legal and theological subjects were published in Cologne, 1575, folio. The best edition of his letters, important for the history of the time (eleven books), is that of Baluze (Paris, 1682). The *Stabat Mater* and *Veni Sancte Spiritus*, and other sacred hymns, are said to have been written by him. Honorius III succeeded him.

*Innocent XI.* (Benedict Odescalchi) was born at Como, in 1611, served, in his youth, as a soldier, in Germany and Poland, took orders, at a later period, and rose through many important posts, until he was elected pope in 1676, on the death of Clement X. He was eminent for his probity and austerity; he zealously opposed nepotism (q. v.) and simony, restrained luxury and excess, and even prohibited women from learning music. Though hostile to the Jesuits, whose doctrine of probabilities he publicly disapproved, and attacked sixty-five of their opinions in the decree *Super quibusdam axiomat. moralibus*, yet he was obliged to condemn Molinus and the Quietists. He determined to abolish the privileged quarters (the ground for a considerable distance around the palaces of certain ambassadors in Rome, which was considered as foreign territory, in which criminals were out of reach of the authorities); but Louis XIV., the vainest of monarchs, would not yield to so just a claim, occupied Avignon, and imprisoned the papal nuncio in France; in consequence of which, the authority, and particularly the acknowledgment of the infallibility of the pope, received a severe blow, by the *IV. Propositiones Cleri Gallicani*, in 1682. (See *Infallibility and Gallican Church*.) These disputes were highly favourable to the English revolution, as it induced the pope, in 1689, to unite with the allies against James II., in order to lower the influence of Louis XIV. His conduct in this respect has led many Catholics to assert that he sacrificed the Catholic religion to his personal resentment; and it was pointedly said, that "to put an end to the troubles of Europe, it was only necessary for James II. to become a Protestant, and the pope a Catholic." Bayle, however, judiciously observes, that the extreme predominance of any great Catholic sovereign is injurious to the interests of the papacy, and mentions the similar conduct of Sixtus V., another able pope, in relation to Philip II. of Spain and Queen Elizabeth of England. Innocent died August 12, 1689, at the age of seventy-eight, leaving behind him the character of an able and economical pontiff, and of an honest and moral man. Had he not died, an open rupture with France might have ensued. Alexander VIII. succeeded him.

**INNS OF COURT.** The colleges of the English professors and students of common law are called *inns*, the old English word for the houses of noblemen, bishops, and others of extraordinary note, being of the same signification as the French *hôtel*. It is not possible to determine precisely the antiquity of the establishment of inns of court. The received opinion is, that societies of lawyers, which, before the conquest, held their chief abodes for study in ecclesiastical houses, began to be collected into permanent residences, soon after the court of common pleas was directed to be held in a fixed place,—a

stipulation which occurs in the great charters both of king John and Henry III. In these houses exercises were performed, lectures read, and degrees conferred; that of barristers, or, as they were first styled, *apprentices* (from *apprendre*, to learn), answering to bachelors; that of sergeants (*servientes ad legem*) to doctors. The inns of court were much celebrated for the magnificence of their revels. The last of these took place in 1733, in the Inner Temple, in honour of Mr Talbot, when he took leave of that house, of which he was a benchers, on having the great seal delivered to him. Fortescue, lord chancellor of England in the reign of Henry VI., says in his treatise *De Laudibus Legum Angliæ*, that in his time, there were about 2000 students in the inns of court and chancery, all of whom were gentlemen born. In the reign of queen Elizabeth, Sir Edward Coke did not reckon above a thousand students, and the number at present is very considerably less. The inns of court are governed by masters, principals, benchers, stewards, and other officers, and have public halls for exercises, readings, &c., which the students are obliged to attend and perform for a certain number of years, before they can be admitted to plead at the bar. These societies have not any judicial authority over their members; but, instead of this, they have certain orders among themselves, which have, by consent, the force of laws. For light offences, persons are only excommunicated, or put out of commons; for greater, they lose their chambers, and are expelled the college; and, when once expelled from one society, they are never received into any of the others. The gentlemen in these societies may be divided into benchers, outer barristers, inner barristers, and students. The four principal inns of court are the Inner Temple and Middle Temple (formerly the dwelling of the knights Templars, and purchased by some professors of the common law, more than three centuries since); Lincoln's Inn and Gray's Inn (anciently belonging to the carls of Lincoln and Gray). The other inns are the two Sergeants' Inns.

*Inns of Chancery* were probably so called because anciently inhabited by such clerks as chiefly studied the forming of writs, which regularly belonged to the cursitors, who are officers of chancery. These are Thavie's Inn, the New Inn, Symond's Inn, Clement's Inn, Clifford's Inn (formerly the mansion of lord Clifford), Staple's Inn (which belonged to the merchants of the staple), Lion's Inn (anciently a common inn, with the sign of the lion), Furnival's Inn, and Bernard's Inn. These were formerly preparatory colleges for younger students, and many were entered here before they were admitted into the inns of court: now they are mostly taken up by attorneys, solicitors, &c. At the present day, previously to being called to the bar, it is necessary to be admitted a member of one of the inns of court. The regulations of Lincoln's Inn, to which those of the other inns bear a strong resemblance, are alone given in the following account:—The applicant for admission need not be present, but the application may be made through the medium of a third person; the applicant must be recommended to the society by one of its members, or by two housekeepers, who are required to certify that they know the applicant to be a proper person for admission. A bond must also be entered into by the applicant himself and the recommending member, or housekeepers, in the sum of £100, conditioned for the due payment of his fees to the society. The fees are generally more than £6 and less than £8 a year; the expense of admission, in the year 1827, amounted to £31, 16s. Before the student commences keeping his terms for the English law, he must deposit with the society the sum of

£100, which is returned, without interest, if the student dies, or quits the society, or is called to the bar. No deposit is required from those who can produce a certificate of having kept two years' terms in the universities of Oxford, Cambridge, or Dublin, or of being of the faculty of advocates in Scotland, nor from those who are admitted merely for the purpose of being called to the Irish bar. Persons removing from one inn to another are allowed the terms which they have kept in their original inns. A term is kept by the student being present at five dinners during the term; three dinners suffice for three quarters of a term; one dinner, during the grand week, for half a term. The student must keep twelve terms (sixty dinners) before he can be called to the bar, and his name must have been five years on the books, unless he produce a certificate of having taken the degree of master of arts, or bachelor of law, at Oxford, Cambridge, or Dublin, in which case three years will suffice. He must also have gone nine times through a certain ceremony, which is called *performing an exercise*. Exercises are performed thus:—The student is furnished, by the steward of the society with a piece of paper, on which is supposed to be written an argument on some point of law, but, owing to the negligence of successive copyists, the writing now consists of a piece of legal jargon, wholly unintelligible. When, after dinner, grace has been said, the student advances to the barrister's table, and commences reading from this paper; upon which one of the senior barristers present makes him a slight bow, takes the paper from him, and tells him that it is quite sufficient. Students intended for the Irish bar keep eight terms in England, and the remainder in Ireland. When the twelve terms have been kept, and the nine exercises performed, the student may petition the benchers to call him to the bar. Except under very peculiar circumstances, the petition is granted, as a matter of course. After dinner, on the day appointed for the call, the student is required to take certain oaths. He then retires with the benchers to the council chamber, which adjoins the hall, to sign the register of his call. There are certain oaths to be taken in the courts of Westminster hall. These should be taken within six months after the call. No attorney, solicitor, clerk in chancery or the exchequer, unless he has discontinued practice for two years in such branches of his profession, and no person who is in deacon's orders, or under twenty-one years of age, can be called. The expense of being called is between £90 and £100. The three years, during which a student is keeping terms, are spent by him in the chambers of a conveyancer, an equity draftsman, or a special pleader.

INNSBRUCK, INSPRUCK, INNSBRUCK, or INSBURG; the capital of Tyrol, on the Inn, over which there is a bridge; lat. 47° 16' 18" N.; lon. 11° 23' 53" E. The city, 1754 feet above the level of the sea, has considerable suburbs, some fine churches, 10,200 inhabitants, and 574 houses. It contains a university, and a general seminary for Tyrol connected with it, and manufactories of several kinds. The works of art in one of the churches, particularly the statues in bronze of the members of the house of Hapsburg, are celebrated. Not far from Innsbruck is the castle of Ambras, (q. v.) Innsbruck is the seat of the Austrian provincial government for Tyrol, and of the assembly of the estates established in 1816. See *Austria*.

INNUEUDO. In an action for a written libel, or for verbal slander, if the offensive words are not in themselves sufficiently intelligible, or if, without explanation, their slanderous tendency does not appear, it is usual for the plaintiff, in his declaration,

which is the written statement of his complaint, to insert parenthetically into the body of the libel the necessary explanation; as, for instance—He (meaning the plaintiff) is forsworn (meaning that he had perjured himself in prosecuting the said defendant). These comments have the Latin name *innuendo*, signifying *meaning*, because *innuendo*, in former times, was always used instead of the word *meaning*, in these explanations. The general rule with regard to innuendoes is, that they must be merely explanatory, introducing no new matter, but only referring to something previously mentioned.

INO, daughter of Cadmus and Harmonia, second wife of Athamas, king of Thebes, drew upon herself the anger of Juno by nursing the young Bacchus, the son of her sister Semele. In order to favour her own children, she projected the murder of her step-children, Phryxus and Helle. Being warned by their mother, Nephele, who appeared to them in a dream, they saved themselves by flight. Juno was still more highly incensed against Ino by this attempt; she made Athamas, the husband of Ino, mad, and, in his frenzy, he dashed his eldest son by Ino, Learchus, against a rock. Ino fled with her youngest son, Melicerta, and threw herself with him into the sea. The body of the boy was carried by a dolphin to the shore, where king Sisyphus caused it to be buried, and instituted in honour of him the well-known Isthmian games (q. v.), as Ino and Melicerta were made sea-deities, at the prayer of Venus. Ino was worshipped under the name of *Leucothea*. According to another account, the body of Melicerta was at first left unburied, and caused a dreadful pestilence, whereupon the oracle, being consulted, ordered that the body should be buried with the usual rites, and that games should be instituted in honour of Melicerta.

INOCULATION, in medicine, is the introduction, by a surgical operation, of a minute portion of purulent matter into contact with the true skin, for the purpose of exciting artificially a milder form of some contagious disease, and thereby protecting the human system against similar attacks in future; keeping in mind, however, that such a process can be only of efficacy in regard to diseases which attack us only once in the course of our lives. Such, for instance, as small-pox. This fatal and loathsome disease appears to have been unknown to the ancient Greeks and Romans, as no mention is made of it in their writings. It is said to have been first noticed during the siege of Mecca, in 522, when it attacked the Arabian and Abyssinian Christians. But, however that may be, it is at least certain that it raged in Egypt during the siege of Alexandria, in the year 640. It first showed itself in Europe and England, about the time when the crusaders returned from the wars of the Holy land; and the mortality which resulted from it was excessive. And in 1520, when it visited, for the first time, some of the provinces of South America, it proved fatal to not less than one half of the population there.

The practice of inoculation, although long followed in some obscure parts of Wales, seems to have been scarcely known throughout England, till the early part of last century, and its adoption is chiefly due to the exertions of lady Mary Wortley Montague, whose admirable letters are so well known. The small-pox had been raging with great mortality in Turkey for some years previous to her ladyship's going thither; and the practice of inoculation, which had been long known and followed by the poorer classes of European Greeks, had lately been had recourse to by the wealthier inhabitants. Her ladyship had her own son inoculated at Pera, with success; and on her

return to England, exerted herself to procure its adoption at home.

For many years the practice met with the greatest opposition, both from the medical profession and the clergy; and several mistakes, of a serious nature, happened, owing to the nature of the plan being but little understood. A pamphlet, published by Dr Jurin, had a great effect in elucidating the subject, and paving the way for the general adoption of so useful an operation, by placing all the disputed points in a clearer point of view; and showing, by numerous facts, that the inoculated small-pox had proved a perfect security against the recurrence of the disease; and that the hazard of inoculation was infinitely less than that of the natural small-pox. Dr Jurin stated that the number of deaths in London, for forty years preceding, had been 903,798, of which 65,079 were occasioned by the natural small-pox; and that more than one-fourteenth part of mankind died from this disease. Of those who were seized with small-pox, two in seventeen, or nearly one in nine, were carried off by it; and, indeed, the mortality from natural small-pox, in some families of the poor, had even amounted to one in five or six; while, on the contrary, of those inoculated, the proportion of fatal cases was not greater than one in sixty. These arguments were further strengthened by the favourable testimonies of Drs Mead and Frewer, and some public establishments were created in London, for the purpose of diffusing the benefits of this practice, in the year 1746.

About the year 1767, the attention of the public was long and powerfully excited by a new and more successful method of inoculation introduced by Mr Sutton, a surgeon in Essex. It consisted chiefly in shortening the period of medicinal preparation from a month to a few days, and in keeping his patients much in the open air during the whole progress of the disease. Of his great popularity and success some idea may be formed, by the fact, that, in the first year of his practice, he received two thousand, and in the second, six thousand guineas in fees. His plan consisted in abstinence from animal food and fermented liquors during the fortnight of preparation; in the course of which, also, he administered, at intervals, three doses of some alternative mercurial powder over night, followed next morning by a dose of neutral purgative salts. May, June, July, and August, were selected by him as the most fit months for his more delicate subjects. He used recent fluid matter for inoculating, and introduced it under a piece of raised cuticle, taking, if possible, his matter from the arm of another inoculated patient before the eruptive process. A pill, (believed to be of extract of poppies), was given on the night following the operation, and every second night till the eruptive fever came on. The same low scale of diet was enjoined during the course of the disease. If, during the eruptive fever, the skin was dry and hot, some drops were given which produced profuse sweating. In cases where the fever was violent, he used to give a powerful powder or pill (the nature of which he kept secret) and cold water to allay the heat; with draughts of tepid balm tea when perspiration came on. On the ceasing of which, and coming out of the pustules, he enjoined exercise or gestation in the open air, and allowed the use of milk gruel in any quantities. In proportion to the severity of the local symptoms of inflammation, he enjoined a lower scale of diet. Sir George Baker ascribed the success attending this Suttonian method, as it was called, chiefly to the free and cool country air, which also formed part of the regimen and plan adopted by the great Dr Sydenham, in the treatment of the natural small-pox, whilst others of his friends attributed his success

to some secret remedies he used, and to his taking the matter at a very early stage of the distemper. See *Small Pox and Vaccination*.

IN PALCO (*Ital.*); an expression alluding to a stage performance. Oratorios were originally performed in Italy on a stage erected in the church; that is, in *palco*.

IN PONTIFICALIBUS (*Latin*, in the full dress of a priest); frequently applied, in sport, to a person in full dress on any occasion.

INQUISITION. The immediate cause of the erection of the tribunals of faith, was the sect of the Albigenses, the persecution of whom, in the twelfth and thirteenth centuries, made the south of France a scene of blood. (See *Albigenses*.) The project of extirpating the rebellious members of the church, and of extending the papal power at the expense of the bishops, by means of the inquisition, was conceived by pope Innocent III. (who ascended the papal chair in 1198) and was completed by his immediate successors. This tribunal, called the *holy inquisition*, or the *holy office* (*sacrum officium*), was under the immediate direction of the papal chair; it was to seek out heretics and adherents of false doctrines, and to pronounce its dreadful sentence against their fortune, their honour, and their lives, without appeal. The process of this tribunal differed entirely from that of the civil courts. The informer was not only concealed, but rewarded by the inquisition. The accused was obliged to be his own accuser; suspected persons were secretly seized and thrown into prison. No better instruments could be found for inquisitors, than the mendicant orders of monks, particularly the Franciscans and Dominicans, whom the pope employed to destroy the heretics, and inquire into the conduct of bishops. Pope Gregory IX., in 1233, completed the design of his predecessors, and, as they had succeeded in giving these inquisitorial monks, who were wholly dependent on the pope, an unlimited power, and in rendering the interference of the temporal magistrates only nominal, the inquisition was successively introduced into several parts of Italy, and into some provinces of France; its power in the latter country being more limited than in the former. The tribunals of faith were admitted into Spain in the middle of the thirteenth century, but a firm opposition was made to them, particularly in Castile and Leon, and the bishops there maintained their exclusive jurisdiction in spiritual matters. But a change afterwards took place; and while, in other countries of Europe, the inquisition could never obtain a firm footing, but in some fell entirely into disuse, as in France, and in others, as in Venice, was closely watched by the civil power, an institution grew up in Spain, towards the end of the fifteenth century, which was the most remarkable of all the inquisitorial courts in the middle ages, and differed much from the rest in its objects and organisation.

Ferdinand of Arragon, and Isabella of Castile, having united their power, made many efforts to break the strength of the nobles, and to render the royal authority absolute. The inquisition was used as a means of effecting their plans. There were three religious parties in Spain, Christians, Jews, and Mohammedans. The Moors still maintained possession of the last remnant of their empire, the kingdom of Grenada, which was, however, already threatened by the arms of Ferdinand and Isabella. The Jews had their synagogues, and formed a distinct class in the principal cities of Spain. Commerce was principally in their hands; they were the lessees of the king and the nobles, and suffered no oppression, being subject only to a moderate capitation tax, which they had been obliged to pay to the clergy since the year 1302. The riches which they had amassed by their industry,

exposed them to great envy and hatred, which was nourished by the ignorant priests. The sermons of a fanatical monk, Fernando Martines Nunes, who preached the persecution of the Jews as a good work, was the principal cause of the popular tumults in many cities, in 1391 and 1392, in which this unhappy people was plundered, robbed, and murdered. Many Jews submitted to baptism to save their lives, and the descendants of these unfortunate men were, for about 100 years, the first victims of inquisitorial zeal.

In 1477, when several turbulent nobles had been reduced in the southern part of Spain, queen Isabella went to Seville with the cardinal Pedro Gonzales de Mendoza: there this prelate, as archbishop of Seville, made the first attempt to introduce the inquisition. At his command, punishments were publicly and privately inflicted, and it was discovered, among other things, that many citizens of Seville, of Jewish origin, followed, in private, the manners and customs of their fathers. The cardinal charged some of the clergy privately to enlighten the faith of these people, and to make the hypocrites true sons of the church. These teachers brought back many to the faith; but many, who persevered in their opposition to the doctrines of the church, were condemned and punished.

After this prelude, the design was disclosed of extending the inquisition over the whole country; and Mendoza laid the project before the sovereigns Ferdinand and Isabella. They approved of an institution, which, at the same time, suited the persecuting spirit of the age, and could be used as a powerful engine of state. The design was, by means of this institution, which was to be entirely dependent on the court, to oppress those who were, either secretly or openly, Jews or Mohammedans (and many Christian nobles belonged to the party of the Mohammedans, the standing allies of malcontents), to enrich the royal treasury, to which the property of the condemned was confiscated, and to limit the power of the nobles, and even of the clergy. In the assembly of the states, held at Toledo, 1480, the erection of the new tribunal was urged by the cardinal. After the superior branches of administration—the supreme council of Castile, the council of state, the board of finance, and the council of Arragon—had been confirmed by the estates, the cardinal declared that it was necessary to establish a permanent tribunal, to take cognizance of matters of faith, and administer the ecclesiastical police. In spite of all opposition, it was determined to establish a tribunal, under the name of the general inquisition (*general inquisition suprema*), and the new court was soon opened in Seville (1481). Thomas de Torquemada, prior of the Dominican convent at Segovia, and father-confessor to the cardinal Mendoza, had already been appointed by Ferdinand and Isabella, the first grand inquisitor, in 1478. He had 200 familiars and a guard of fifty horsemen, but he lived in continual fear of poison. The Dominican monastery at Seville soon became insufficient to contain the numerous prisoners, and the king removed the court to the castle in the suburb of Triana. At the first *auto da fe* (act of faith), seven apostate Christians were burnt, and the number of penitents was much greater. Spanish writers relate, that above 17,000 gave themselves up to the inquisition, more than 2000 were condemned to the flames the first year, and great numbers fled to the neighbouring countries. Many Jews escaped into Portugal, Africa, and other places.

The pope, however, had opposed the establishment of the Spanish inquisition, as the conversion of an ecclesiastical into a secular tribunal. Soon after the appointment of the new inquisitor, he had directed the archbishop of Toledo, a warm enemy of Mendoza,

to hold a solemn court over a teacher in Salamanca, who was charged with heretical opinions, and the inquisitor-general was repeatedly summoned to Rome. Torquemada, however, did not obey the summons, but sent a friend to defend his cause. The contest between the pope and the Spanish court, was carried on with heat, until 1483, when Sixtus IV. was obliged to yield, and acknowledge Torquemada as inquisitor-general of Castile and Leon. He was also authorized, by the papal bull, to establish inferior courts at pleasure, to remove those judges who had been appointed by the pope, and to regulate the manner of proceeding in inquiries respecting matters of faith according to the new plan. A later bull subjected Arragon, Valencia, and Sicily, the hereditary dominions of Ferdinand, to the inquisitor-general of Castile; and thus the inquisition was the first tribunal whose jurisdiction extended over the two Spanish kingdoms of Castile and Arragon; the Arragouese estates, at their session at Tarragona, in 1484, being obliged to swear to protect the inquisition.

The introduction of the new tribunal was attended with risings and opposition in many places, excited by the cruelty of the inquisitors, and encouraged, perhaps, by the jealousy of the bishops; several places, particularly Saragossa, refused admission to the inquisitors, many of whom lost their lives; but the people were obliged to yield in the contest, and the kings became the absolute judges in matters of faith; the honour, the property, and the life of every subject was in their hands. They named the grand inquisitor; and by them, or under their immediate influence, were his assessors appointed, even the secular ones, two of whom were of the supreme council of Castile, laymen being permitted to hold the office. This tribunal was thus wholly dependent on the court, and became a powerful instrument for establishing the arbitrary power of the king on the ruins of the national freedom; for putting down the clergy, who had previously acknowledged only the jurisdiction of the Roman see; for oppressing the bold nobles, and taking away the privileges of the estates. The property of those who were condemned, fell to the king; and, although it had been granted to the inquisition, it was still at his disposal. Ferdinand and Isabella, indeed, devoted a part of this property to found convents and hospitals; but the church, notwithstanding, lost many possessions by means of the inquisition; and an ordinance, drawn by Torquemada (1487), proves that it was a source of revenue to the king, supplying the treasury, which was exhausted by the war: the inquisitorial chest was, indeed, at that time, drained by so many royal draughts, that the officers could not obtain their salaries.

The first ordinance, by Torquemada, dedicating the tribunal to the service of God and their majesties, bears date 1484. Among other articles are the following, showing the political importance of the institution. In every community, the grand inquisitor shall fix a period, from thirty to forty days, within which time, heretics, and those who have relapsed from the faith, shall deliver themselves up to the inquisition. Penitent heretics and apostates, although pardoned, could hold no public office; they could not become leasees, lawyers, physicians, apothecaries, or grocers; they could not wear gold, silver, or precious stones, or ride, or carry arms, during their whole life, under penalty of being declared guilty of a relapse into heresy; and they were obliged to give up a part of their property for the support of the war against the Moors. Those who did not surrender themselves within the time fixed, were deprived of their property irrevocably. The absent also, and those who had been long dead, could be condemned,

provided there was sufficient evidence against them. The bones of those who were condemned after death, were dug up, and the property which they had left reverted to the king.

Torquemada died in 1493, and was buried in the Dominican convent at Avila, which had been built with the property taken from heretics, and was a monument of his cruel zeal. He had resigned his office two years before, being afflicted with the gout. According to another account, Torquemada did not retire so quietly from the stage. It is said that, suspecting that Ferdinand and Isabella, whom the wars with the Moors had involved in great pecuniary embarrassments, would be moved by the great sums which were offered them, to limit the privileges of the inquisition, and disturbed by this apprehension, he went to the royal palace, with a crucifix under his mantle. "I know your thoughts," said he boldly to the sovereigns; "behold the form of the crucified one, whom the godless Judas sold to his enemies for thirty pieces of silver. If you approve the act, yet sell him dearer. I here lay down my office, and am free from all responsibility; but you shall give an account to God." He then laid down the cross, and left the palace.

At first, the jurisdiction of the inquisition was not accurately defined; but it received a more regular organization by the ordinance of 1484, establishing branches in the different provinces of Spain, under the direction of the inquisitor-general. In later times, the supreme tribunal was at Madrid. The inquisitor general presided. Of the six or seven councillors, whom he appointed on the nomination of the king, one, according to an ordinance of Philip III., must be a Dominican. He had a fiscal, two secretaries, a receiver, two relators, and several *officials*, as they were called, who were appointed by the grand inquisitor, in concurrence with the king. The inquisitorial council assembled every day, except on holidays, in the royal palace; on the last three days of the week, two members of the council of Castile were present at the meeting. It was the duty of some of the officers (*calificadores*) to explain whether any act or opinion was contrary to the doctrines of the church; others were lawyers, who merely had a deliberative voice. The sentence of the inquisition was definitive. It was the duty of the fiscal to examine the witnesses, to give information of criminals, to demand their apprehension, and to accuse them when seized. He was present at the examination of the witnesses, at the torture, and at the meeting of the judges, where the votes were taken. It was the duty of the registers, besides the preparation of the necessary papers, to observe the accuser, the witnesses, and the accused, during their legal examination, and to watch closely the slightest motion by which their feelings might betray themselves. The officials were persons sent by the court to arrest the accused. A *secuestrador*, who was obliged to give sureties to the office, kept an account of the confiscated property. The receiver took the money which came from the sale of sequestered property, and paid the salaries and drafts on the treasury. It is computed, that there were in Spain above 20,000 officers of the inquisition, called *familiares*, who served as spies and informers. These places were sought even by persons of rank, on account of the great privileges connected with them. As soon as an accuser appeared, and the fiscal had called upon the court to exercise their authority, an order was issued to seize the accused. In an ordinance of 1732, it was made the duty of all believers, to inform the inquisition if they knew any one, living or dead, present or absent, who had wandered from the faith, who did observe or had observed the law of Moses,

or even spoken favourably of it; if they knew any one, who followed or had followed the doctrines of Luther; any one who had concluded an alliance with the devil, either expressly or virtually; any one who possessed any heretical book, or the Koran, or the Bible in the Spanish tongue; or, in fine, if they knew any one who had harboured, received, or favoured heretics. If the accused did not appear at the third summons, he was excommunicated.

From the moment that the prisoner was in the power of the court, he was cut off from the world. The prisons, called *holy houses* (*casas santas*), consisted of vaulted apartments, each divided into several square cells, which were about ten feet high, and stood in two rows, one over the other. In the upper cells, a dim ray of light fell through a grate; the lower were smaller and darker. Each dungeon had two doors. The inner, which was bound with iron, had a grate, through which food was introduced for the prisoner. The other door was opened, early in the morning, to air the cell. The prisoner was allowed no visits from his friends or relations; no book of devotion was given him; he was compelled to sit motionless and silent in his dark cell, and, if his feelings found vent in a tone of complaint, or even in a pious hymn, the ever-watchful keeper warned him to be silent. Only one captive was usually placed in each cell, unless for the purpose of making discoveries. At the first hearing, the accused was called upon to confess his guilt. If he confessed the crime of which he was accused, he pronounced his own sentence, and his property was confiscated. If he declared himself innocent, contrary to the testimony of the witnesses, he was threatened with torture. The advocate who was appointed to defend him, could not speak to him, except in the presence of the inquisitors. The accused was not confronted with the accuser nor the witnesses before the court, neither were they made known to him; and he was often subjected to the torture, to extort a confession, or to explain circumstances which had not been fully explained by the witnesses. Those who escaped death by repentance and confession, were obliged to abjure their errors, and to swear to submit to all the pains and penalties which the court ordered. Imprisonment, often for life, scourging, and the loss of property, were the punishments to which the penitent was subjected. He was made infamous, as well as his children and grand-children. Wearing the *san-benito* (the blessed vest of penitence, a sort of coarse, yellow tunic, with a cross on the breast and back, and painted over with devils) was a common method of punishment. An accused person, who was fortunate enough to escape before the officers of the inquisition could seize him, was treated as an obstinate heretic. Summonses were posted up in all the public places, calling on him to appear. If he did not do this within a certain time, and if the evidence of the witnesses proved the charges, he was delivered over to the secular power, and burnt in effigy. Persons who had been dead more than forty years, were condemned, and, though their children retained possession of the property they had inherited, yet they were dishonoured, and rendered incapable of holding any public office.

When sentence of death was pronounced against the accused, the *holy auto da fe* was ordered. This usually took place on Sunday, between Trinity Sunday and Advent. At daybreak, the solemn sound of the great bell of the cathedral called the faithful to the dreadful spectacle. Men of high rank pressed forward to offer their services in accompanying the condemned, and grantees were often seen acting as familiars to the inquisition. The condemned appeared barefooted clothed in the dreadful *san benito*, with a

conical cap (*carroza*) on their heads. The Dominicans, with the banner of the inquisition, led the way. Then came the penitents, who were to be punished by fines, &c., and after the cross, which was borne behind the penitents, walked the unfortunate wretches who were condemned to death. The effigies of those who had died, and the bones of the dead who had been condemned, appeared in black coffins, painted over with flames and hellish forms; and the dreadful procession was closed by monks and priests. It proceeded through the principal streets of the city to the church, where a sermon was preached, and the sentence was then pronounced. The convicted stood, during this act, before a crucifix, with an extinguished taper in their hands. As "the church never pollutes herself with blood," a servant of the inquisition, when this ceremony was finished, gave each of those who had been sentenced a blow with the hand, to signify that the inquisition had no longer any power over them, and that the victims were abandoned (*relaxados*) to the secular arm. A civil officer, "who was affectionately charged to treat them kindly and mercifully," now received the condemned, bound them with chains, and led them to the place of execution. They were then asked in what faith they would die. Those who answered the Catholic, were first strangled; the rest were burnt alive. The *autos da fé* were spectacles to which the people thronged as eagerly as to the celebration of a victory. Even the kings considered it a meritorious act to be present, with their courts, and to witness the agonies of the victims.

In this manner did the inquisition proceed, in the times of its most dreadful activity. The Spaniards found their personal freedom so much restrained, even in the early period of the existence of this office, that one of the principal requests of the disaffected, in the reign of Charles I. was, that the king should compel the inquisition to act according to the principles of justice. But the important influence which this court had, in the course of the following century, both on the state and on the moral character of the Spaniards, could not, at that time, have been anticipated. This noble and high-spirited people were more debased by the dark power of the inquisition than by any other instrument of arbitrary government, and the stagnation of intellectual action, which followed the discovery of America, concurred, with other fatal causes, to diminish the industry of the people, to weaken the power of the state, and to prevent, for a long time, any progress to higher degrees of moral and intellectual improvement. In more modern times, when the spirit of persecution was restrained in almost all other countries of Europe, the original organisation of the inquisition was but little changed; still the dread of this dark court gradually diminished. The horrible spectacle of an *auto da fé* was seldom witnessed during the last century, and the punishments of the inquisition were confined, in a considerable degree, to those men who had become obnoxious to justice. In 1762, the grand inquisitor having, contrary to the express will of the king, published a bull, excommunicating a French book, was exiled to a monastery at a distance from Madrid. A royal decree forbade the inquisition to issue any commands without the consent of the king, and required the grand inquisitor, in the condemnation of books, to conform to the laws of the land, and to make known his prohibition only by virtue of the power given him by his office, and not with the citation of bulls. The decree also ordered that, before prohibiting any book, the author should be cited, that his defence might be heard. In 1770, during the administration of Aranda, the power of the inquisition was limited to the punish-

ment of obstinate heretics and apostates, and it was forbidden to imprison any of the king's subjects, without first fully proving their guilt. In 1784, it was determined that, if the inquisition instituted a process against a grandee, a minister, or, in short, against any officer of rank, its acts must be subjected to the royal inspection.

If we consider the principal acts of the inquisition during the eighteenth century, we shall see that, notwithstanding the restraint exercised over it, it still remained an instrument which, under favourable circumstances, might exert a terrible influence. There were sixteen provincial inquisitions in Spain and the colonies, all subject to the supreme tribunal. As late as 1763, we find that, at an *auto da fé* at Llerena, some obstinate heretics were committed to the flames, and, in 1777, the inquisition armed itself with all its terrors against a man who was guilty of nothing more than imprudence—the celebrated Olavides (q. v.); and, in 1780, a poor woman of Seville was declared guilty of witchcraft, and was burnt alive at the stake. With all the limits which had been set to its power, with all the mildness of the tribunal, whose principal officers, under the preceding reigns, had been mostly men of intelligence and moderation, still the odious spirit of the institution, and the unjust form of procedure, survived; and, until the moment when it was abolished by Napoleon (December 4, 1808), the inquisition continued to be a powerful obstacle to the progress of the human intellect. The inquisition published annually a catalogue of prohibited books, in which, among some infidel and immoral works, many excellent or innocent books were included. All the attempts of enlightened men, towards effecting the destruction of this antiquated instrument of a dark policy, during the two last reigns, were without connexion, and therefore without effect, and they sank under the artifices which an all-powerful favourite, the clergy and the inquisition employed for their common advantage. The process, concluded as late as 1806, against two learned and excellent canons—Antonio and Geronimo Cuesta, whose destruction their unworthy bishop, under the protection of the prince of peace, had striven to effect—was the last sign of life in this terrible court, and plainly shows that intrigue, when united with the secret power of the inquisition, had great influence in Spain, even in recent times; and the decision of the king, which declared the accused innocent, and condemned the proceedings of the inquisition as contrary to law, was yet tender towards the inquisitors, and confirmed the general opinion, which punished those who had fallen into the power of the inquisition with the loss of public esteem.

According to the estimate of Llorente, the number of victims of the Spanish inquisition, from 1481 to 1808, amounted to 341,021. Of these, 31,912 were burnt, 17,659 burnt in effigy, and 291,456 were subjected to severe penance. Ferdinand VII. re-established (1814) the inquisition, which had been abolished during the French rule in Spain; but, on the adoption of the constitution of the cortes (1820), it was again abolished, and was not revived in 1823, by the advice of the European powers.

In Portugal, the inquisition was established, after a long contest, in 1557. The supreme tribunal was in Lisbon; inferior courts, established in the other cities, were subject to this. The grand inquisitor was nominated by the king, and confirmed by the pope. John of Braganza, after the delivery of the country from the Spanish yoke, wished to destroy the inquisition. But he succeeded only in depriving it of the right of confiscating the property of the condemned. On this account, he was excommunicated after his death, and his wife was obliged to permit his

body to receive absolution. As the Spaniards took the inquisition with them to America, so the Portuguese carried it to India, and established it at Goa. In the 18th century, the power of the inquisition in Portugal was restrained by the ordinance which commanded that the accuser of the court should furnish the accused with the heads of the accusation and the names of the witnesses, that the accused should be allowed to have the aid of counsel, and that no sentence of the inquisition should be executed until confirmed by the royal council. The late king abolished the inquisition, not only in Portugal, but also in Brazil and the East Indies, and caused all its records at Goa to be burnt.

The inquisition restored in Rome by Pius VII., has jurisdiction only over the clergy, and is not therefore dangerous to those who are not Catholics. In 1826, it condemned to death Caschiur, a pupil of the Propaganda, who was appointed patriarch of Memphis, but not accepted by the viceroy of Egypt. The pope changed the punishment into imprisonment for life. His crime is unknown.

Among the late works on the inquisition, are Llorente's History of the Spanish Inquisition (Paris, 1815; in English, London, 1827), and Antonio Puig-blanch's Inquisition Unmasked, from the Spanish (London, 1816). The Records of the Inquisition, from the original MSS., taken from the Inquisitorial Palace at Barcelona, when it was stormed by the Insurrectionists in 1819 (1828), contain interesting reports of some particular cases.

**INQUISITION, PROCESS** or. This phrase is used, on the continent of Europe, to designate that kind of criminal process in which the court takes upon itself the investigation of an offence, by appointing one of its members to collect the proofs of the crime, as, for instance, in the German courts. Thus the process of inquisition differs from what is called the *process of accusation*, where the court stands between the government and the accused, as it does in England and the United States. In civil cases, the process of accusation prevails also in the German courts. See *Process*; also *Accusation*, and *Act*.

**INSANITY, MENTAL DERANGEMENT.** By these general terms we understand every form of intellectual disorder, whether consisting in a total want or alienation of understanding, as in idiocy, or in the diseased state of one or several of the faculties. Medical writers have adopted different systems of classification, in their treatment of this subject; but perhaps the most convenient is that which comprises all mental diseases under the four heads of mania, melancholy, demency or fatuity, and idiocy. Lunacy, in its proper sense, implies an influence of the changes of the moon (Latin, *luna*) on the state of the mind or body, of which modern science cannot recognise the existence. It is true that many diseases are periodical in their returns, and it is not improbable that paroxysms of violence among insane persons, may be really increased at the time of a full moon, by the effect of the shadows of clouds, and other objects, as ghosts are generally seen by moonlight; but any other lunar influence neither experience nor science can discover. The causes of insanity are divided by modern writers, into physical and moral. Every excess of passion, joy, grief, anger, fear, anxiety, &c., may become a moral cause of insanity. Great political or civil revolutions have always been observed to be attended with numerous cases of mental derangement. Pinel observed this phenomenon in France, after the revolution of 1789, and Dr Rush describes similar effects, in the United States, after the war of the revolution. Strong religious excitement often produces similar results, although in many cases, religious enthusiasm is only a form of

the malady, and not a cause. Madden (*Travels in Egypt, Nubia, &c.*, 1830) states that insanity is rare among the Mohammedans, and attributes it to their consoling belief in the certainty of their salvation. Dr Rush thinks that the disease is more common among civilised communities than with savages, on account of the greater influence of moral causes on the former. The physical causes of insanity are various and numerous; diseases of various kinds, and of different organs, bodily injuries or wounds, excessive indulgence in eating, drinking, and other sensual pleasures, privation, exposure to extreme cold or heat, &c., are among them. Insane persons are often, however, in good health, and dissection does not always detect a disordered condition of the organs. Philosophy is not sufficiently acquainted with the mutual action and reaction of the body and the mind on each other, to decide how far the disordered state of the one is consistent with the sanity of the other; nor is it certain that there is any one organ or function which must be diseased to affect the mind. Climate, age, occupation, and sex, are often mentioned as causes influencing insanity. But climate does not appear to be an exciting cause, although the moral, civil, religious, or physical condition of a nation may have rendered the disorder more frequent in some countries than in others. The seasons, however, appear to exercise an influence, and it is generally observed that the cases of insanity are most numerous in the hottest part of the year. Suicides are most frequent when the thermometer is above 84°. Although many circumstances, both physical and moral, appear to render the female sex most liable to insanity, it does not appear that the number of insane females is greater than that of males: drunkenness being more prevalent among the latter, may be one cause of this. In both sexes, the most active period of life, from thirty to forty, presents the greatest number of cases. In regard to occupation, sufficient data do not exist to show that there is any decided predominance of cases in any particular employment.

Idiocy is either a congenital or an acquired defect of the intellectual faculties, or, as Pinel defines it, as obliteration, more or less absolute, of the functions of the understanding and the affections of the heart. Congenital idiocy may originate from a malformation of the cranium, or of the brain itself; the senses are often wanting, or defective, and life is commonly of short duration. Acquired idiocy proceeds from mechanical injury of the cranium, or from an injury or a disease of the brain, from excess in sensual indulgences, intemperance, fatigue, and from moral causes. In this the senses may be partially affected, or quite destroyed, and life often continues to old age. Absolute idiocy admits of no cure; but it should not too hastily be concluded that a patient is in this state. The term *demency* (fatuity, the *μωπη* of the Greeks, and *dementia* of later writers) is applied to a complete or partial hebetude of individual faculties, particularly those of association and comparison, producing confusion of thoughts, loss of memory, childishness, a diminution or loss of the powers of volition; it differs from idiocy in being curable. Persons are reduced to this state, because exterior objects make too weak an impression on them; the sensations are, therefore, feeble, obscure, and incomplete; the patient does not form a correct idea of objects, nor compare, associate, or abstract ideas. It is often merely an attendant of other diseases, or other forms of insanity, and is frequently quite temporary, though it often becomes permanent.

*Mania* (Greek, *μανια*, madness) is a species of mental derangement, characterised by the disorder of one or several of the faculties, or by a blind impulse

to acts of fury. Adults are the principal subjects. A nervous temperament, an irritable constitution, predispose to it. Females are more exposed to it than males, particularly at the period when menstruation begins or ceases, during pregnancy, and after delivery. Violent emotions, a dissipated life, excess in any indulgence, sometimes produce it. The disorder of the intellectual faculties is manifested by extravagant, gay, gloomy, or furious emotions; the gestures and words seem automatic. Sometimes the conversation is rational, but the patient bursts out, at intervals, into paroxysms of rage, attacking every thing which he meets; the moral affections also seem deadened, and the most ferocious hatred is displayed towards the most natural objects of love. It is sometimes cured, but sometimes remains stationary, and sometimes is converted into demency. Repeated bleeding, hellebore, cold water poured upon the head, scouring, and other means of terror, were formerly employed as remedies. At present, solitude, warm baths, low diet, &c., are more commonly applied.

*Melancholy* (from *μῆλας*, black, and *χολή*, bile), called also *monomanie* (Greek, *μονα*, only, and *μανία*, madness); a species of mental disorder, consisting in a depression of spirits. Some dark or mournful idea occupies the mind exclusively, so that, by degrees, it become unable to judge rightly of existing circumstances, and the faculties are disturbed in their functions. The powers of the soul become weakened, we might say crippled. If these feelings are allowed to attain a height at which the power of self-control is lost, a settled gloom takes possession of the mind. Consciousness, however, may still continue; the person knows his state. But if consciousness is also lost, and this state becomes continual, the melancholic patient is insensible to the world around him; he only lives within himself, and there only in the circle of one fixed idea. In this disordered state of the feelings, the other faculties may still continue to act, although the mode and result of their operation will necessarily be influenced by the existing disease. There may be reflection in the actions of the patient, but the reflection proceeds from false premises. Several kinds of melancholy are distinguished; the distinctions are founded, however, mostly on the cause of the disease. A very common cause of melancholy is love. He who loses the great object of his wishes and affections, which has absorbed, we might almost say, the whole activity of his soul, feels more than jealousy at the success of a fortunate rival; existence appears to him a blank, and himself the most unhappy of men. Another frequent cause of melancholy is gloomy views of religion. A constant excitement of the feelings by the awful picture of the eternal punishment of sin, often produces absolute despair. The use of such means, to prepare the mind for the reception of deep religious principle, has not unfrequently led to distraction and suicide. Repeated failures in enterprises pursued with anxious zeal, may also reduce the faculties of a man so much, that he becomes wrapt up solely in the idea of his misfortune. Melancholy patients often flee from men, haunt solitary places, such as graveyards, and are given to nocturnal rambles. The course of the disease is various; sometimes it lasts a series of years; sometimes it ceases of itself, or is cured by medical aid; more frequently it passes over into other kinds of insanity, or into bodily diseases, as dropsy of the chest, consumption, dropsy in the head, apoplexy, &c. It is said that melancholy people rarely suffer from the gonorrhea, or are attacked by epidemic diseases. Several physical causes are enumerated as inducing it, particularly a superfluity of black bile (hence the Greek name). Various derangements in the physical system tend to occasion it, as debility of the nerves, violent

flow of the blood to the heart, superfluity of thick blood. (For the light in which the law regards melancholy patients, see the article *Non Compos.*) Burton's *Anatomy of Melancholy* consists chiefly of extracts from ancient authors, illustrating the causes, effects, and cure of that morbid affection. The author's own reflections are few, but they are original, ingenious, and striking. The subject of insanity is fully treated in the following works: Burrow's *Commentaries on the Causes, Forms, Symptoms, and Treatment of Insanity* (London, 1828); Pinel, *Traité sur l'Aliénation Mentale*; Voisin, *Des Causes Morales et Physiques des Maladies Mentales* (1826); Willis, *Treatise on Mental Derangement* (1823).

INSCRIPTION, in archaeology, is used to designate any monumental writing, intended to commemorate some remarkable event, to preserve the name of the builder of a monument, or of the person in whose honour it was erected, &c. Inscriptions are one of the most important sources of history, particularly for the earlier periods of nations, when other written documents are rare or entirely wanting, and tradition is the only medium of historical knowledge. After the invention of the alphabet, the earliest application of the art of writing is by engravings on wood, stone, or metals; and, after other and more convenient materials have come into common use, this method is still preferred for many purposes, on account of the greater durability of the material. We have inscriptions, therefore, from all nations who have arrived at a certain stage of civilization, on walls of temples, tombs, triumphal monuments, tablets, vases, &c., containing laws, decrees, treaties, religious legends, moral, philosophical or scientific precepts, chronological tables, &c., generally contemporary with the events they commemorate. Indian, Persian, Egyptian, Phœnician, Etruscan, Grecian, Roman, &c., inscriptions, have been diligently studied, and have made important revelations in the hands of learned and ingenious men. The Egyptian monuments are numerous, and covered with inscriptions, which the learned have only recently been able to decipher. They are in the hieroglyphic, hieratic, and demotic characters, in the Coptic or old Egyptian language, and have already served to throw much light on the imperfect accounts of historians, and to supply many deficiencies in our knowledge of Egyptian history. (See *Hieroglyphics*.) The Phœnician monuments, bearing inscriptions, are few. The language was employed on the medals of the Phœnician cities till the time of Alexander, and was carried to Carthage, Cadiz, &c., by this commercial people. Barthélemy (*Mém. de l'Acad. des Belles Lettres*, tom. xxxii.), Swinton, Chishull, have written on this subject, but it is still involved in obscurity. The inscriptions on the ruins of Pasargadæ, Babylon, and Persepolis (q. v.), are in the arrow-headed character, of which there are two kinds, the Persian and the Babylonian: the former consists of three sorts of characters, all of which are commonly used in the same inscription. The Persian inscriptions, so far as they have been deciphered, appear to contain merely names of the kings, with wishes for their welfare. The Babylonian characters are of two sorts, and are sometimes called *naïl-headed*, in distinction from the Persian. The little that is known relating to the arrow-headed characters may be found in Heeren's *Ideen*, i. 1; Hager's *Diss. on the Babylonian Inscriptions* (London, 1801); Von Hammer's *Fundgruben des Orients*, iv. 4; Alexander's *Travels from India to England* (London, 1827). The ancient Arabic inscriptions are in the Cufic character (see *Cufic Writing*), and the old Hebrew are in the Samaritan character. Greek art was carried from its native soil into all the countries around the Mediterranean, by commerce and colonies, and, by the arms of Alex-

ander and his successors, even into the remote East. The Greek language appears on a great number of monuments in this extensive region, written in different characters, according to the age of the inscription, and in different dialects in different countries. The Doric dialect is perceptible in the monuments of Dorian colonies, and so with the others. In this manner, where there are two cities or artists of the same name, it may be determined to which the work of art should be attributed by the dialect of the inscription. The forms of the Greek letters underwent some changes, which must be attended to in the study of inscriptions: the absence or admission of certain letters (as H and  $\eta$ ), the different forms of the sigma ( $\Sigma$ , C, or S), of the epsilon (as E or  $\epsilon$ ), of the O (as round or square,  $\square$ ), of the lambda (as  $\Lambda$  or L), &c., may aid in determining the age of a monument. The early inscriptions are often from right to left, sometimes in the *boustrophedon* (q. v.), which was abandoned about the middle of the fifth century before Christ. (See the 8th vol. of the *Thesaur. Antiq. Græc.* of Gronovius; the works of Pococke, Chandler, and other travellers; Montfaucon's *Palæographie Græca*; *Mém. de l'Académie des Inscriptions*.) The Etruscan inscriptions, on vases and monuments, have occasioned much dispute among the learned. Niebuhr, in his Roman History, says, that the assertion of Dionysius, that the Etruscans spoke a peculiar language, deserves full credit, since it was, in his time, a living language; and it is fully confirmed by the inscriptions extant, in the words of which no analogy with the Greek or Latin can be detected; and he adds in a note, that, among all the Etruscan words of which explanations have been pretended, only two have been really explained. See, however, Lanzi's *Saggi di Lingua Etrusca* (Rome, 1789, 3 vols.); Gori's *Museum Etruscum*; and Inghirami's *Monument. Etruschi* (1826). From the Eugubian Tables, discovered in 1444, Buonarroti, Gori, and others endeavoured to form an alphabet: the former thought he had discovered twenty-four, the latter sixteen letters. The Latin inscriptions are the most frequently met with. They are found on monuments of all descriptions; some very ancient ones are yet preserved. (See Grævius's *Thesaur. Antiq. Rom.*, vol. 4, and Fabricius's *Bibliotheca Latina*, lib. iv. c. 3.) Inscriptions are called *bilingual*, when the characters are taken from two different languages, as was sometimes done by the vanquished people, in compliment to their conquerors. Inscriptions are sometimes repeated in different languages, or in different characters, on the same monument; as, for instance, in the language of the province and in the Greek or Latin, in the times of the Greek and Roman empires. Some of the general collections of inscriptions are, Gruter's *Inscriptiones antiquæ, Cura Grævii* (Amsterdam, 1707, 2 vols., folio); Muratori's *Thesaurus Vet. Inscrip.* Milan, 1739, 4 vols.; Consult, also, the works of Selden, Prideaux, Chandler, and Mattaire on the Parian (Arundelian) marbles (q. v.); the *Archæologia Britannica* 1779 to 1822, 21 vols., 4to; the *Mémoires de l'Académie des Inscriptions*; and the numerous works on particular countries, cities, or collections. See *Medal*, *Vase*, *Obelisks*, *Pyramids*, &c.

INSCRIPTIONS, ACADEMY OF. See *Academy*.

INSECTIVORA; animals which live, or are thought to live, on insects. Divisions of this sort cannot be very exact. Some *insectivora* drink blood with delight, or eat grass occasionally, and some of the beasts of prey, whose principal food is larger game, are fond of flies. Among birds, the *insectivora* form a very numerous class.

INSECTS. See *Entomology*.

INSOLVENCY. See *Bankrupt*.

INSTANCE. On the European continent, a court is said to be of the *first instance*, when it has original jurisdiction of a case; of the *second instance*, when it has appellate jurisdiction from a lower court; of the *third instance*, when it has appellate jurisdiction from courts of the second instance. In some cases, generally criminal, a court may be of the first or second instance, according to the place where the process was begun; for instance, if a man is tried in Prussia for a high crime, and found guilty, he appeals, and the case is sent to another criminal court, chosen by the government, which, in this case, is of the second instance; while, in the next case, perhaps, the situation of the two courts may be reversed. To *absolvere ab instantia* means to absolve a person from an accusation, without carrying through the process.

INSTINCT (from the Latin *instinctus*); that impulse, produced by the peculiar nature of an animal, which prompts it to do certain things, without being directed, in acting thus, by reflection, and which is immediately connected with its own individual preservation, or with that of its kind. Thus the newborn duck hastens to the water, the infant sucks, without being taught to do so; all animals eat when they feel hunger, drink when they are thirsty, by instinct. All the instincts of animals are directed to the preservation either of the individual or of the genus. They appear in the selection of food, avoiding of injurious substances, taking care of their young, and providing for them before they are born; as the bird, for instance, builds its nest to receive its future progeny. The instinct of motion, and the opposite instinct, which compels the bird, for instance, to remain on her eggs at the period of incubation, are equally strong. The building of dwellings is, in the case of many animals, a highly curious exercise of instinct; as, for instance, in the case of the beaver and the bee. They are evidently actuated by instinct, as they always succeed the first time they attempt it. Certain instincts lead to certain changes; for instance, to migrating, or to coupling at certain times, to building nests, and expelling the young when they are fledged, and able to take care of themselves. Instinct sometimes misleads; as, for instance, the fly lays its eggs in the flower of the *stapelia hirsuta*, deceived by the smell of this plant, which resembles that of meat in a state of putrefaction. The young, in this case, perish for want of food. Two things are worthy to be remarked. Men often act from instinct, when least aware of it, and often explain actions in other animals, by instinct, in which they cannot be actuated by it, but in which memory, and the power of combination, must necessarily be supposed. Numerous anecdotes of dogs prove this. The intelligence of animals is an extremely interesting subject, and though there are several highly valuable works on it, yet it is far from having been thoroughly investigated.

INSTITUTE, THE NATIONAL. This learned body, which was organised after the first storm of the French revolution, during which all the academies of learning and arts in France had perished, was formed by the decree of the 3d Brumaire of the year 4, from the *Académie Française*, the *Académie des Sciences*, and the *Académie des Belles Lettres et des Inscriptions*. Its object was the advancement of the arts and sciences by continual researches, by the publication of new discoveries, and by a correspondence with the most distinguished scholars of all countries, and especially by promoting such scientific and literary undertakings as would tend to the national welfare and glory. The institute was composed of a number of members residing at Paris, and an equal number of associates (*associés*) in the different parts of the republic. Each class could also choose eight learned foreigners as associates. It

was at first divided into three classes, each of which was subdivided into several sections. The first class embraced the physical and mathematical sciences, the second the moral and historical, and the third literature and the fine arts. The number of active members, exclusive of the *associés*, was limited to 144. The national institute received, however, its final organization by a decree of the 3d Pluviose of the year 11 (January 23, 1803). It was then divided into four classes—1. the class of the physical and mathematical sciences, consisting of sixty-five members; 2. the class of the French language and literature, consisting of forty members; 3. the class of history and ancient literature, of forty members; and, 4. the class of the fine arts, with twenty-eight members. In the last years of the imperial government, the title of the national institute was exchanged for that of the *imperial institute*. The restoration of the Bourbons gave rise to new changes in this learned body, which restored it, in some degree, to its original condition. A royal ordinance of March 21, 1816, first restored the former names of the classes, so that the name of *institute* was applied only to the whole body collectively. The same ordinance assigned the first rank to the *Académie Française*, as being the oldest; the next rank to the *Académie des Inscriptions et Belles Lettres*; the third to the *Académie des Sciences*; and the last to the *Académie des Beaux Arts*. These united academies were under the personal direction of the king, and each had an independent organization, and a free exercise of the powers committed to them. To each academy were attached ten honorary members, who had merely the right of being present at the meetings. Such of the former honorary members and academicians as had returned with the court, became, as a matter of right, honorary members of their respective academies. A list of names, appended to the royal decree, determined the members.

The *Académie Française* is well known to be charged with the composition of a French dictionary. As every one who has brought a *vaudeville* on the stage with success, thinks himself entitled to a place among the forty members of this class, these places afford the most fruitful subjects for squibs and satire.

The *Académie des Inscriptions et Belles Lettres* has lately limited its members to thirty. It has always been considered a great mark of distinction to be an *associé étranger* of this class. The number of corresponding members is unlimited. The most distinguished scholars, both in and out of Europe, are thus connected with the society. Committees of this academy superintend the erection of public monuments, and the preservation and description of those already in existence. Sacy, Daunou, Caussin, Letronne, Boissonade, were chosen from this academy to continue the *Notices et Extraits des Manuscrits, de la Bibl. du Roy*. The editing of the *Journal des Savans*, to which the members of all the academies contribute, devolves principally on this academy. They have the distribution of prizes of considerable value.

The *Académie des Sciences* is divided, as formerly, into the two principal departments of the physical and mathematical sciences, and retains most of its earlier regulations, made in the time of the republic. The number of its *associés étrangers* is limited to two.

The *Académie des Beaux Arts* has five sections. A committee of this academy is charged with the publication of a dictionary of the fine arts.

The annual changes which take place in the academies, may be learned from the calendar called *l'Annuaire Royal de France*, published by Firmin Didot, printer to the institute.

INSTITUTIONES. See *Corpus Juris*, and *Civil Law*.

INSTRUMENT, in music; any sonorous body, artificially constructed for the production of musical sound. Musical instruments are divided into three kinds—wind instruments, stringed instruments, and instruments of percussion. Of the stringed instruments among the ancients, the most known are the lyre, psalterium, trigonum, simmicium, epandoron, &c. The principal wind instruments were the tibia, fistula, tuba, cornu, and lituus; those of percussion, the tympanum, cymbalum, crepitaculum, tintinnabulum, and crotalum.

INSTRUMENTAL MUSIC; music produced by instruments, as contradistinguished from *vocal* music. The term *instrumental* is particularly applied to the greater compositions, in which the human voice has no part. The first instrument invented was probably the pipe or flute. An idle shepherd might very naturally, from accident, or in imitation of the effects of the wind, blow through a simple reed, and thus invent the pipe, from which the flute would readily originate. The pipe is, in fact, found among many savages. The invention of stringed instruments, as they are more artificial, is of later origin. The instrumental music of the Greeks was confined to a few instruments, among which the flute, the cithara, the sackbut, though not precisely like those instruments among the moderns, were the most important. The violin was invented in the middle ages, and soon became the principal instrument, taking its place above the flute, though the latter is of much more ancient origin, because the playing on a stringed instrument is less fatiguing, and the tone of the violin is more distinct from the human voice, and, therefore, better fitted to be used with it; besides, the instrument permits much more perfect execution. Until the middle of the last century, the Italian composers used no other instruments in their great pieces, than violins and bass-violos; at that time, however, they began to use the hautboy and the horn; but the flute has never been much esteemed in Italy, particularly in music exclusively instrumental. These were the only wind instruments in Italy, used in instrumental music, until the end of the last century; and even to this day, the Italians use wind instruments much less than the Germans, and particularly the French. Since Mozart, every instrument has been used, which appeared adapted to answer a particular purpose. This is the cause of the fewness of the notes in the Italian, and of their great number in German, and their excess in the modern French scores. In general, symphonies and overtures, solos, duets, terzettos, quartettos, quintettos, &c., sonatas, fantasias, concerts for single instruments, dances, marches, &c., belong to instrumental music.

INSURANCE is a contract, whereby, for a stipulated consideration, called a *premium*, one party undertakes to indemnify another against certain risks. The party undertaking to make the indemnity is called the *insurer* or *underwriter*, and the one to be indemnified, the *assured* or *insured*. The instrument, by which the contract is made, is denominated a *policy*; the events or causes of loss insured against, *risks* or *perils*; and the thing insured, the *subject* or *insurable interest*. *Marine* insurance relates to property and risks at sea; insurance of property on shore against fire, is called *fire* insurance; and the written contracts, in such cases, are often denominated *fire policies*. Policies on lives are another description of this contract, whereby a party, for a certain premium, agrees to pay a certain sum, if a person, to whose life it relates, shall die within a time specified. These policies, however, usually make an exception of death by suicide.

There was a kind of insurance in use, among the Greeks and Romans, called *bottomry* or *respondentia*, which is, where the owner of a vessel or goods, borrows money upon bottomry (q. v.) upon the vessel, or upon respondentia on the goods, for a certain voyage, agreeing, that if the ship or goods arrive at a certain port, the money shall be repaid, and also interest, exceeding the legal rate; but if lost by the risks specified in the bond, before arriving at the port named, the lender is to lose the money loaned. This risk of losing the whole capital, is the cause of the excess of interest allowed in case of the arrival of the ship or goods; and it is called *marine interest*, which ought to be equal to the common rate of interest, added to the rate of premium, for insuring the ship or goods for the same voyage against the same risks. This sort of contract was anciently in use, and, as the laws then gave less security, or, at least, as credit and confidence were not so widely diffused, and correspondence was less extensive among merchants, it was usual for the lender to send some person with the property, to receive repayment of the money loaned and the marine interest, at the port where the risk terminated. In modern times, it is not usual to send any person with the property, who would be of no service during the voyage; and, at its termination, some agent of the lender, at the port of arrival, if he is not there himself, looks after his interest. The wide extension of correspondence, among merchants of all parts of the world, in modern times, gives a facility for this purpose, and renders the execution of this, as well as other commercial contracts, more economical, and, at the same time, more secure.

Contracts of insurance, strictly so called, are of modern invention; and their importance, in relation to commerce, is scarcely inferior to that of bills of exchange. Every merchant is liable to losses and reverses, by the change of the markets. The risks of this description may, however, be calculated upon with some degree of probability; but those of fire, the perils of the seas, or capture, cannot be so well estimated; and, when they come, they would, in many cases, bring ruin upon the merchant, if it were not for the system of insurance, the object of which is, to apportion the losses from these disasters among all those whose property is exposed to the same hazards. If, for instance, all persons engaged in trading were to enter into a general agreement to contribute for the losses of each other, occasioned by those casualties, in the proportions of the amounts that they should respectively have at risk, every individual would then only run the risk of the proportion of losses occurring upon the general aggregate of property at risk. But as such a general combination would be complicated, and practically inconvenient, a very simple system is devised, by means of insurance, for effecting the same object; for one person—the underwriter—agrees to take upon himself those risks, for a hundred merchants, more or less, for a certain premium on each risk, calculating that the premiums on the fortunate adventures will compensate him for the losses he may incur on those which are unfortunate, and leave him some surplus, as a compensation for his time and trouble; and a little experience will enable him to calculate the chances with very considerable accuracy. The result accordingly is, that all the persons who procure their property to be insured by him, in effect, mutually contribute for each other's losses, by the bargain of of each with the common receiver of the contributions of all.

This contract was subjected to a system of definite rules, much earlier in Italy and France than in England; and as the contract is the same in prin-

ciple, and very similar in form in different countries, the rules of construction adapted to it in one country, are equally applicable in another. The system of rules collected in the French ordinance of the *marine* in the year 1681, and which had already, in general, become established in France, Italy, and the Netherlands, is still in force, and daily applied throughout the commercial world, not only in Europe, but also in America. But it was late before these principles of insurance were intimately incorporated into the law of England. Until the time of lord Mansfield's becoming chief-justice of the court of king's bench in England, about the middle of the eighteenth century, the law of insurance was in a very rude state. It was, before that time, the more general practice to make what were called *wagering policies*, in which one party agreed, for a certain premium, to pay the other a certain sum, in case a particular vessel should not arrive at a certain port of destination, on account of certain perils; without any question being made whether the party insured had any interest in the ship or cargo; so that, in addition to the contracts of insurance against real loss, many contracts of the above sort were made by persons who had no interest whatever in the property to which the contract related. These contracts of insurance, in the case of persons really interested in the property, were a very imperfect indemnity, since they only extended to the case of a defeat of the voyage; whereas, great damage is often sustained by the ship or cargo, notwithstanding they may both arrive at the port of destination. But, at about the period already mentioned, Magens, a merchant, who had removed from Hamburg to London, published his very elaborate work on insurance, in the latter place, containing all the laws and regulations of the different commercial countries of the continent, on this subject, and presenting its leading doctrines, in relation to partial losses and general averages, and giving a great number of examples of adjustments of losses, of both descriptions. Lord Mansfield, at about the same time, expelled from the administration of this branch of law the narrow, quibbling, and technical doctrines with which it had been previously too much infested. The foundation was then laid for that magnificent and truly scientific superstructure of legal principles and practical rules, which has been the work of the joint labours of the English and American jurists, from that period down to the present day. The courts of the United States have contributed their full share towards the formation of the admirable system by which the commerce of the world is now protected and promoted; and instances might readily be referred to, of discussion and opinions on this subject in the American courts, which, in learned research, liberality of views, scientific principles, and logical precision, will not suffer by a comparison with those of any other country.

This contract, considered as one of indemnity—and as such only it ought always to be regarded, and by no means confounded with gambling,—requires, in the first place, a subject; something must be at risk, and the thing so at risk must be described in the contract; and no party can be injured, unless he has an interest in the subject which he is liable to lose, or in respect to which he is liable to suffer by the perils insured against; and the contract must specify against what perils or risks the underwriter undertakes to make indemnity; and the party insured must, at the time of making the contract, state, fairly and honestly, all the material circumstances within his own private knowledge, which may enable the underwriter to form an estimate of the risk. This is peculiarly a contract, in which the assured a

bound to fairness and good faith in effecting it, and the underwriter to liberal promptness in complying with his stipulation to make indemnity.

**INSURRECTION.** See *Revolution*.

**INTAGLIOS**; engraved gems. See *Gem Sculpture*.

**INTEGRAL.** See *Calculus*.

**INTERPERANCE.** See *Temperance*.

**INTENSENESS** is the state of being raised or concentrated to a great degree. A *verbum intensivum*, in grammar, is a verb which expresses increased force; as, *facisco*, I do earnestly, from *facio*, I do; *petisco*, I seek earnestly, from *peto*, I seek. The German *betteln*, to beg alms, may, perhaps, be considered as the intensive form of *bitten*, to ask, unless it be considered to denote properly a repetition of the act of asking, in which case it will belong to the class of *verba frequentativa*, such as *facito*, I do repeatedly; *lectito*, I read often.

**INTERDICT**; an ecclesiastical censure in the Catholic church, the effect of which, taken in its most extended sense, is, that no kind of divine service is celebrated in the place or country under the sentence; the sacraments are not administered, the dead not buried with the rites of the church. This interdict is called *real* or *local*, whilst the personal interdict regards only one or more persons. We shall here speak of the former. Even Catholic writers admit that the interdict has been often abused for interested purposes, and has produced licentiousness in the countries and provinces subjected to it, by depriving them of religious service for a length of time. (See the Catholic *Dictionnaire de Théologie*, Toulouse, 1817, article *Interdict*.) And no one, acquainted with history, can deny that interdicts have been productive of rebellion and all kinds of disorder; they served, however, in the barbarous age of modern Europe, as a check against the power of the monarchs. It is a mistake to suppose that Gregory VII. (q. v.) was the inventor of this mighty engine of ecclesiastical power. It can be proved to have existed before his time; but it is true that he used it oftener and more powerfully than any of his predecessors. The eleventh century was pre-eminently the century of interdicts. Adrian IV. laid Rome itself under an interdict, for the purpose of compelling the senators to expel Arnold of Brescia and his followers. Innocent III. laid France under an interdict in 1200, and England in 1208. (See *Philip Augustus*, *John*, and *Innocent*.) Popes or bishops sometimes mitigated the rigour of the interdict. Thus we read in the Chronicle of Tours, that the vaticum and baptism were allowed to be administered during the interdict, under which France was laid, as above-mentioned, and which lasted nine months. Innocent III. finally permitted preaching and confirmation to take place during this period, and even the administering of the eucharist to crusaders and foreigners. And Gregory IX., about 1230, on account of the "great scandal" caused by the interdicts, permitted mass to be said once a week, without ringing the bells, and with the doors closed. Boniface VIII. (1300) ordered the mass to be said without singing, every day, with closed doors, except on Christmas, Easter, Pentecost, and Assumption, when ringing the bells, singing, and open doors were allowed. Magdeburg was four years under an interdict, because the archbishop of the city had been murdered. John XXII. took off the interdict by a bull. Interdicts were gradually recognised to be inconsistent with the spirit of the time; and, when Paul V. laid Venice under an interdict in 1606, the churches were not closed, nor divine service interrupted, and only a minority of the bishops acknowledged it. In the beginning of the same century, some interdicts, pro-

nounced by bishops, excited much attention. It was not unfrequent, in the middle ages, for princes to request bishops to lay the territories of their vassals under an interdict. The interdict must be announced, like the excommunication, in writing, with the causes, and is not to be imposed until after three admonitions. The penalty of disobedience to an interdict is excommunication. Writers of the Gallican church say that the pope has no right to lay France under an interdict, and the parliaments refused to register them. Interdicts are not to be confounded with the simple *cessatio a divinis*, or the disuse of religious ceremonies, which takes place when a church has been polluted, e. g., by a murder committed in it.

**INTEREST** is the allowance made for the loan or forbearance of a sum of money, which is lent for, or becomes due at, a certain time; this allowance being generally estimated at so much per cent. per annum, that is, so much for the use of £100 for a year. Interest is either *simple* or *compound*. *Simple interest* is that which is allowed upon the principal only, for the whole time of the loan or forbearance. The money lent or forborne, is called the *principal*; the sum paid for the use of it, the *interest*. The interest of £100 for one year, is called the *rate per cent.*, and the sum of any principal and its interest, together, the *amount*.—*Compound interest* is that which arises from any sum or principal in a given time, by increasing the principal, at fixed periods, by the interest then due, and hence obtaining interest upon both interest and principal. The accumulation of money, when placed at compound interest, after a certain number of years, is exceedingly rapid, and in some instances appears truly astonishing. One penny, put out at five per cent. compound interest, at the birth of Christ, would, in 1810, have amounted to a sum exceeding in value 357,000,000 of solid globes of standard gold, each in magnitude as large as this earth! (the exact number of globes, according to this computation, is 357,474,600); while at simple interest, it would have amounted only to 7s. 7½d.

**INTERIM** (of Augsburg). After the overthrow of the Smalcaldic league, the despotic emperor Charles V., in order to place Germany in its former condition, in regard to religion as well as politics, issued a decree, to be observed until a general council should be assembled. This decree was therefore called the *interim*, and settled, *pro tem.*, the constitution, the doctrines and discipline of the church in Germany. At the diet of Augsburg (1548) it received the force of a law of the empire. Nothing was conceded to the Protestants but the cup in the Lord's supper, and the marriage of priests; in every other respect the doctrines and ceremonies of Catholicism, from which they had been free for more than twenty years, were to be restored. The Protestants, however, contrived to gain time by negotiations and compliances, until the treaty of Passau (1552) and the peace of Augsburg (1555) secured to them complete religious freedom. See *Peace, Religious*.

**INTERLUDE**; a piece of music, a dance, or a short dramatic scene, generally between two performers of different sexes, exhibited between the acts of a serious opera, to vary the entertainment. The interlude is not an invention of the moderns; the ancients were acquainted with certain short pieces, loosely connected, which served to make an easy transition from one play to another, and to occupy the interval between the two. At present, the term *interlude*, or *intermezzo*, is applied principally to small comic operas, written for one, or at most for two persons, but not connected, in any way, either with the play which precedes, or that which follows. On account of the very limited number of persons in the interlude, little more is required of such pieces

than humour and comic power. According to Arteaga, modern interludes were at first madrigals, which were sung between the acts by several voices, and were connected with the play. One of the oldest and most beautiful is *Il combattimento d'Apolline col Serpente*, by Berdi. But these madrigals soon lost their primitive form, and represented some action.

**INTERMENT.** See *Funeral Rites*.

**INTERNUNTIVS**; the messenger or representative of the pope, sent to small foreign courts and to republics. The papal ambassador to emperors and kings is called *nuntius*. (See *Nuncio*.) The ordinary Austrian ambassador at Constantinople is also called *internuntius*.

**INTERPOLATION**, in algebra, signifies the finding of an intermediate term in a series, its place in the series being given. There are analytic formulas for the execution of interpolations.

In philological criticism, *interpolation* signifies the insertion of spurious passages in a work. In printed texts, suspected passages are often enclosed in brackets.

**INTERPRETATION** (from the *Latin*); the explanation of the true meaning of an author or instrument. (For the interpretation of the Scripture, see *Eregesis*; for interpretation in politics, see *Construction*.) On the continent of Europe, if a law is interpreted by the legislative power, it is called *interpretatio authentica*; if by the unwritten usage, *interpr. usualis*; if in a scientific way, *interpr. doctrinalis*, which may be *interpr. grammatica*, if the meaning is found out from the words according to grammatical rules, or *interpr. logica*, if the meaning is found by internal reasons, or *interpr. critica*, if obtained by correcting the text. The *interpr. logica* is called *extensiva*, if it extends the law beyond the literal meaning of the words, or *restrictiva*, if it restricts the application of the law to fewer cases than the words would imply, and *declarativa*, if it settles vague expressions. In the interpretation of laws, it is of the first importance to ascertain the meaning of the lawgivers; the intention of the person who drew up an instrument in the nature of a contract, is not so decisive, because there the intention of the party with whom the contract was made, is equally important. Furthermore, the meaning which words bore at certain periods, is important in the explanation of old laws, and a knowledge of local usages is often essential for interpretation. In former times, laws and instruments were drawn up with a profusion of words, to avoid, as far as possible, leaving any thing to construction; but experience has proved this view to be erroneous, for nothing is clearer than the simplest language; and, though there will always be room left for interpretation, except in mathematics, yet this increases with the profusion of words and the endeavour to embrace every detail.

**INTERREGNUM.** See *Germany*.

**INTERVAL**; the difference in point of gravity or acuteness between any two sounds. Taking the word in its more general sense, we must allow that the possible intervals of sound are infinite; but we now speak only of those intervals which exist between the different tones of any established system. The ancients divided the intervals into simple or uncomposite, which they call *diastema*, and composite intervals, which they call *systema*. The least of all the intervals in the Greek music was, according to Bacchius, the enharmonic diesis, or fourth of a tone; but our scale does not notice so small a division, since all our tones concur in consonances, to which order only one of the three ancient genera, viz., the diatonic, was accommodated. Modern musicians consider the *semitone* as a simple interval, and only call those composite which consist of two or

more semitones: thus from B to C is a semitone, or simple interval, but from C to D is two half tones, or a compound interval.

**INTERVENTION**, in politics; a word which has been used, particularly since the congresses of Troppau, Laybach, and Verona (see *Congress*, and *Holy Alliance*), to express the armed interposition (*intervention armée*) of one state in the domestic affairs of another. The right of armed intervention has never been so distinctly pronounced and acted upon, as in modern times, since the congress of Vienna. It was a natural consequence of the holy alliance, and the congresses of rulers, or their representatives, assembled to prop the pillars of despotism. (See *Italy*, *France*, since 1819, *Naples*, and *Spain*.) Such armed interventions as have lately taken place in Europe, arise from the fellow-feeling of sovereigns, who claim the right of assisting each other against their subjects, and directly contravene the right of independent development which belongs to the character of a nation.

The works of Fiévée (*De l'Espagne et des Conséquences de l'Intervention Armée*, 3d edit., Paris, 1823), of Bignon (*Du Congrès de Troppau*, Paris, 1821, and *Les Cabinets et les Peuples depuis 1815. Jusqu'à la Fin de 1822*, 3d edit., Paris, 1823), of De Pradt, &c., as well as the important debates on the subject of the French war of intervention in Spain, in both the French chambers, and in the British parliament, 1823, have exhausted the subject. The first statesmen of Britain and France then exerted themselves to throw light on the doctrine of armed intervention, which had already been applied to the Poles, treating it both in its general principles and in its application to particular cases. Among the state papers relating to the right of intervention according to the latest principles, the following are particularly important:—the declaration of the British minister, lord Castlereagh, of the 19th January, 1821, and the circular of Verona, 14th December, 1822. With regard to the application of this doctrine, by the European powers, to the Spanish American colonies, Britain and the United States declared themselves categorically, in 1824, that no congress of the sovereigns was held on that subject. The United States are the power which acts most implicitly upon the principle of non-intervention. (See *Independence*.) Recently, the interest of most of the European monarchs, which induced them to pronounce at Laybach the right of armed intervention, has prompted them to deny it in the protocol of the five great powers, issued at London, in 1831, denouncing foreign intervention in the affairs of Belgium.

**INTESTINE** (*intestinum*, from *intus*, within). The convoluted membranous tube, that extends from the stomach to the anus, receives the ingested food, retains it a certain time, mixes with it the bile and pancreatic juice, propels the chyle into the lacteals, and covers the feces with mucus, is so called. The intestines are situated in the cavity of the abdomen, and are divided into the small and large, which have, besides their size, other circumstances of distinction. The small intestines are supplied internally with folds, called *valvula conniventes*, and have no bands on their external surface. The large intestines have no folds internally; are supplied externally with three strong muscular bands, which run parallel upon the surface, and give the intestines a second appearance; they have also small fatty appendages, called *appendicula epiploica*. The first portion of the intestinal tube, for about the extent of twelve fingers' breadth, is called the *duodenum*; it lies in the epigastric region, makes three turnings, and, between the first and second flexure, receives by a common opening, the pancreatic duct, and the

*ductus communis choleodochus*. It is in this portion of the intestines that chylification is chiefly performed. The remaining portion of the small intestines, is distinguished by an imaginary division into the *jejunum* and *ileum*. The *jejunum*, which commences where the *duodenum* ends, is situated in the umbilical region, and is mostly found empty; hence its name: it is every where covered with red vessels, and, about an hour and a half after a meal, with distended lacteals. The *ileum* occupies the hypogastric region and the pelvis, is of a more pallid colour than the former, and terminates by a transverse opening into the large intestines, which is called the *valve of the ileum, valve of the cæcum, or the valve of Tulpinus*. The beginning of the large intestines is firmly tied down in the right iliac region, and, for the extent of about four fingers' breadth, is called the *cæcum*, having adhering to it a worm-like process, called the *processus cæci vermiformis, or appendicula cæci vermiformis*. The great intestine then takes the name of *colon*, ascends towards the liver, passes across the abdomen, under the stomach, to the left side, where it is contorted like the letter S, and descends to the pelvis; hence it is divided, in this course, into the *ascending portion, the transverse arch, and the sigmoid flexure*. When it has reached the pelvis, it is called the *rectum*, from whence it proceeds in a straight line to the anus. The intestinal canal is composed of three membranes, or coats; a common one from the *peritoneum*, a muscular coat, and a villous coat, the *villi* being formed of the fine terminations of arteries and nerves, and the origins of lacteals and lymphatics. The intestines are connected to the body by the mesentery; the *duodenum* has also a peculiar connecting cellular substance, as have likewise the colon and rectum, by whose means the former is firmly accreted to the back, the colon to the kidneys, and the latter to the *os coccygis*, and, in women, to the vagina. The remaining portion of the tube is loose in the cavity of the abdomen. The arteries of this canal are branches of the *superior and inferior mesenteric*, and the *duodenal*. The veins evacuate their blood into the *vena porta*. The nerves are branches of the eighth pair and intercostals. The lacteal vessels, which originate principally from the *jejunum*, proceed to the glands in the mesentery.

INTONATION, in music, relates both to the consonance and to the strength or weakness of sounds. Intonation not only includes the act of tuning, but the giving to the tones of the voice or instrument that occasional impulse, swell, and decrease, on which, in a great measure, all expression depends. A good intonation is one of the first qualifications in the higher walks of execution.

In church music, those antiphonies are called *intonnations*, which are first sung by the priest, and then responded by the choir or the congregation; also the short sentence, mostly taken from the Bible, which the minister sings before the collect, and which is responded by the choir or community. Such are the *Gloria* (q. v.), "The Lord be with you," &c.

INTOXICATION; the state produced by the excessive use of alcoholic liquids. It comes on gradually, and several stages may be noticed in its progress. The first is the condition expressed by the phrase *urged with wine*. In this stage, the circulation of the blood becomes somewhat more rapid, and all the functions of the body are exercised with more freedom. The excitement, however, is not so great as to produce a surcharge of blood in the head or lungs. In this state, some of the powers of the soul seem to act more freely; the consciousness is not yet attacked; the fancy is more lively; the feeling of strength and courage is increased. In the second stage, the effect on the brain is more decided. The peculiarities of

character, the faults of temperament which, in his sober moments, the individual could control and conceal, manifest themselves without reserve; the secret thoughts are disclosed, and the sense of propriety is lost. In the next degree, consciousness is still more weakened; the balance of the body cannot be kept, and dizziness attacks the brain. In the next degree, the soul is overwhelmed in the tumult of animal excitement; consciousness is extinguished; the lips utter nothing but an incoherent babble; the face becomes of a glowing red; the eyes are protruded; sweat streams from the pores; and the victim of intoxication falls into a sleep resembling the stupor of apoplexy. For some further remarks on this subject, see the article *Temperance*.

INTRENCHMENT; any work that fortifies a post against the attack of an enemy. The word is generally used to denote a ditch or trench with a parapet. Intrenchments are sometimes made of fascines with earth thrown over them, of gabions, hogsheds, or bags filled with earth, to cover the men from the enemy's fire. See *Retrenchment*.

INTRIGUE; an assemblage of events or circumstances, occurring in an affair, and perplexing the persons concerned in it. In this sense, it is used to signify the nodus or plot of a play or romance, or that point wherein the principal characters are most embarrassed through artifice and opposition, or unfortunate accidents and circumstances.

INTROITO; a passage of the fifth verse of the 42d Psalm, with which the Catholic priest, at the foot of the altar, after having made the sign of the cross, begins the mass; whereupon the servitor answers with the rest of the verse; after which the whole Psalm is recited alternately by the priest and the servitor. In masses for the dead, and during Passion week, the Psalm is not pronounced.

INTUITION (from the Latin *intueor*, I look steadfastly at, gaze upon; in German philosophy, *Anschauung*), would mean, according to its etymology, in its narrowest sense, an image in the mind, acquired directly by the sense of sight. In the English use of the word, it is confined to mental perception, and signifies the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case, the mind perceives the truth, as the eye does the light, merely by being directed towards it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. This part of knowledge, says Locke, is irresistible, and, like the sunshine, forces itself immediately to be perceived, as soon as ever the mind turns its view that way. It is on this intuition that all the certainty and evidence of our other knowledge depend; this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater. The German *Anschauung*, which literally signifies the same as *intuition*, is used to signify any notion directly presented by an object of sense. The transcendental philosophy acknowledges also intuitions which live in us (distinct from ideas obtained by reasoning), in consequence of the direct perception of the internal sense, as the intuition of the Divine. Kant distinguishes empiric intuitions (those conveyed by the senses from external objects), and pure intuitions (*reine Anschauungen*), or intuitions *a priori*, which are the basis of the former; for instance, *space* and *time*: as nothing can be perceived by our senses except either in space or time, our notions of these must precede the empiric intuitions.

INVALIDS; in its general sense, a person who is sickly or indisposed; in its more particular sense, soldiers and officers, who are disabled for foreign

service by wounds, disease, or age, and who are generally maintained for life in public establishments (hospitals), at the public expense. The Athenians had a law, providing for the public maintenance of persons disabled in war. The Romans also made some, though small, provision for invalids. At a later period, they were taken care of in the monasteries. Philip Augustus of France first formed the plan of an hospital for invalids. But, as pope Innocent III. would not permit this institution to be placed under the direction of the bishop, the king relinquished the plan. Louis XIV. was the first who carried this design into execution. Between 1671 and 1679, he erected a splendid hospital at Paris, in the suburb of St Germain. A church, a department for the sick, a governor, and other officers, are attached to it. Guards are stationed, and all other forms observed which are customary in fortified posts. A soldier must have served ten years, to be received into this hospital on account of poverty or infirmity. The invalids who mount guard are the only ones who bear arms. This institution suffered very much at the commencement of the revolution; but, during the imperial government, it was put in a better condition than ever. The architect of the hospital was Brimont. It is composed of five courts surrounded by buildings. A vast esplanade, bordered by rows of trees, and decorated with a fountain, gives the principal facade, towards the Seine, a noble perspective. The *hôtel* has a library of 20,000 volumes; it is capable of containing 7000 men, and is governed by a marshal of France. The church is considered a *chef-d'œuvre* of French architecture; its dome supports a lantern, which is surmounted by a cross 308 feet high. From the dome were formerly suspended 3000 colours, taken from different nations; but they were taken down and burnt by the invalids, at the time when the allies entered Paris, that they might not be retaken. Works in statuary and painting, by Lafosse, Boullogne, Coppel, Coustou, Coysevox, &c., adorn the ceilings, niches, and other parts of the buildings. Frederic the Great, in 1748, built the hospital at Berlin, with the inscription *Læso et invicto militi*. The British marine hospital, at Greenwich, is the first institution of this kind.

INVENTION, in science, is distinguished from *discovery*, as implying more creative combining power, and generally signifies the application of a discovery to a certain purpose. But the distinction is often very nice, and it is difficult, in many cases, to say which word is most suitable. Every invention includes a discovery. When Archimedes exultingly exclaimed, *Eureka* (I have found it), after he had discovered, in the bath, that his body, in the fluid, displaced an amount equal to its own bulk, he *discovered*; but he *invented* when he applied the hydrostatic law, thus discovered, to determining the specific gravity of different substances. Inventions owe their origin, as discoveries do, either to chance, to some happy idea suddenly striking the mind, or to patient reflection and experiment. Many inventions belong to the two former heads. Of the third class of inventions, late years afford many instances, owing to the great attention which has been paid to the natural sciences. As man, in modern times, is always inclined to consider that which is nearest him the most important, he generally considers the inventions of his age as far surpassing those of other times; but the study of history teaches us more modesty. The invention of the screw, of the wheel, of the rudder, of the double pulley, may be compared with any modern inventions in mechanical science, and could not, moreover, have been struck out at once by chance. The history of inventions is one of the most interesting branches of historical sciences,

exhibiting, in a striking light, the stages of progress and decline in human activity, and the great variety of motives which have actuated different ages. G. Ch. A. Busch has published a *Manual of Inventions*, 12 vols., (Eisenach, 1802 to 1822, in German). Beckmann's *History of Inventions* (Leipsic, 1780-1806), has been translated into English, 3 vols.

INVENTION OF THE CROSS. The Roman Catholic church celebrates a feast, May 3, in honour of the finding of the cross on which Christ was executed. The search was made by the order of St Helena, mother of the emperor Constantia 326, and the cross was said to have been found in the ruins of Calvary. The story is told by S.

INVERKEITHING; a royal burgh and in Fifeshire, occupying a pleasant elevation from the northern shore of the Firth of which here forms a noble bay, affording anchorage for ships of all descriptions, in the men of war on the Leith station, which in gales occasionally run up hither from Leith for safety; here also foreign vessels usually quarantine, for whose accommodation a lazaretto is moored at the mouth of the harbour for the purpose of receiving their merchandise and furniture under the superintendence of an inspector. This bay is the harbour, which has been improved and deepened, so that ships can now in or discharge their cargoes alongside the wharves and commodious quays constructed close to the town. Inverkeithing is a very ancient place, been a royal residence in the time of David I. It contained convents of Franciscan and Dominican friars, the remains of one of which, termed The Priory, is still exempt from the magisterial authority exercised over the rest of the burgh. At present it consists of one spacious street, intersected by a number of others of inferior width. It was made a burgh by William the Lion, and has since received charters from other kings, all ratified by James VI. The parish is three miles and a half in length by about one in breadth, and includes the island of Inchgarvie, the fishing village of Bruce Haven and that of North Queen's Ferry, between which and South Queen's Ferry, on the opposite side of the Forth, passage-boats are in constant requisition. Population in 1831, 3,189.

INVERNESS-SHIRE; an extensive highland county of Scotland, bounded on the east by those of Aberdeen and Elgin or Moray, on the west by the Atlantic Ocean, on the north by the shire of Ross and the Moray Firth, and on the south by the shires of Argyle and Perth, including also the islands of North and South Uist, Eigg, and several others of the Hebrides. It comprehends the districts, Badenoch, Lochaber, Moidart, Glenelg, and Glenngary, and extends across the entire country from the North Sea to the Atlantic, having the noble Lochs Ness, Oich, and Lochy, running in a direct line through the centre, or vale of Glenmorenahalabin, from north-west to south-east, and uniting the northern and western oceans by means of the great Caledonian Canal, cut from the Moray Firth to that arm of the sea termed Loch Linnhe. This extensive vale is bounded on each side by wild and barren tracts, terminating in lofty mountains, of which the celebrated Ben Nevis, whose summit is capped with eternal snow, is elevated 4370 feet above the level of the sea. The district is intersected by numerous rapid streams, which, uniting at various points, form the river Benuly-Foyers, noted for its stupendous falls, Lochy and Spey, with others of minor consideration, all of them well stocked with salmon, trout, and different other kinds of fish. There are evident remains of extensive forests, consisting of several tracts of oak, fir, mountain-ash,

and other wood, and in the neighbourhood of the lakes and rivers are large patches of arable lands, well cultivated, though the farmers are mostly engaged in rearing black cattle and sheep for the southern markets. Springs, impregnated with sulphur and iron, are met with, as are veins of lead, silver, and iron ore, but the absence of coal is severely felt. Gaelic is generally spoken, and is still the most prevalent language. Since the construction of the military stations, Fort Augustus, Fort George, and Fort William, to overawe thelanders, after the expulsion of the Stuarts, the of communication with the south has been equally expeditious and convenient, by the m of various roads and bridges, at the public , which are kept in excellent repair.

imits anciently assigned to this shire, comd the whole of that division of Scotland th of the Grampians, the extent of which t to be considered rather as a vice-royalty secondary division of the kingdom, though her amals of Scotland its kings appear to but a doubtful authority over this part lm, the Norwegian princes then possessing ce of Caithness, with the isles of Orkney and, while the lords of the isles held ver the Hebrides, and the adjacent dis- ne main land, and the rest of the country ed by rude and barbarous tribes, who regular authority or government. No to have been taken towards the division s so late as 1633, but in the act passed by rliament of Charles I. against the clan ' sheriffs of Perth, Dumbarton, Angus, dling, Banff, Elgin, Cromarty, &c., &c. r noticed, though there is no mention of thness, Nairn, Ross, and Sutherland, ver, appear to have been all distinct e of Inverness, at the Restoration, and

no material alteration in the limits of the latter have since been made. In Glenelg are the remains of several circular towers, similar to those so common in the Hebrides, with galleries, and flights of steps ascending to the top, which is quite open. Inverness-shire is the country of the clans Cameron, Fraser, Grant, Macpherson, Macdonald, Macintosh, &c. Population, in 1831, 94,997.

The town of Inverness is situated on the southern coast of the Moray Firth, near the mouth of the river Ness, from which it takes its name, and by which it is divided into two parts, connected by a noble stone bridge of seven arches, thrown across the stream, the southern division of the town being the principal and by far the most populous. The harbour has depth of water sufficient not only for the admission of vessels of 200 tons burden, but to enable them to take in or discharge their cargoes alongside its commodious quay; while ships of a superior class and tonnage may ride with perfect safety on the Firth, about a mile below. This town, a century ago, consisted chiefly of barns, granaries, kilns, &c.; and so lately as the rebellion of 1745, presented an appearance little better than a confused heap of ruins; but since that period it has been wholly rebuilt, and is still improving in all quarters. It is now a large, well-built place, containing several spacious streets of handsome houses, three national churches, one Episcopalian church, a Methodist chapel, a court-house, and tolbooth, of elegant design, with a stately tower, surmounted by a spire of beautiful proportions, a general post-office, a public academy of high repute, erected in 1790, and conducted by a rector and four masters; and several other schools, four of which, here and in other parts of the parish, owe their origin to the Society for propagating Christian

Knowledge. Inverness is the capital of the county, indeed, of the Highlands, and displays much of the elegance of a capital, being the residence of many genteel families. Population, in 1831, 14,324.

INVERSION (from the *Latin*), literally *turning in*, is a word variously used. In grammar, it is contradistinguished from *construction*, and means the arrangement of words according to the order in which the ideas follow in the writer's mind, and not according to the usual grammatical construction. The inversion is regulated by the object of the writer or speaker. The French language is the most confined in this respect, and has made the natural construction its first law of arrangement. The Greek and Latin, on the contrary, are extremely free in the use of inversion, and, under certain circumstances, can use almost any order of words. The German is not so free as the Greek, but much freer than the French. Inversion seems necessary for the perfection of a language, though it leads to many aberrations from good sense. As a figure in rhetoric, inversion is used to direct the attention to a particular point, without changing the meaning, as, for instance, 'My peace I give to you,' or, 'The palm of victory he soon hath gained, the faithful warrior.'

Two numbers, powers, or quantities are said to be in an inverse proportion, if one diminishes as the other increases; for instance, the fleetness and the power of a horse are in an inverted proportion.

The term is also used, in tactics, to denote the disordered arrangement of a battalion, when the platoons composing it stand in a reversed order. When the platoon which usually stands on the extreme right becomes, by a manoeuvre, the extreme left, the second platoon from the right becoming the second from the left, and so on, then the man who before stood at the right extremity of the platoon should properly stand at the left; but if, instead of so doing, he still stands at the right, the position of the battalion is inverted. In the following series,

8 7 6 5 4 3 2 1  
q-p | o-n | m-l | k-i | h-g | f-e | d-c | b-a,

let *a, c, e, g, i, l, n, p*, be the men on the right of their respective platoons, when the battalion stands regularly drawn up; then the following order would represent the battalion inverted, thus:

1 2 3 4 5 6 7 8  
b-a | d-c | f-e | h-g | k-l | m | l | o-n | q-p.

Here platoon 1 stands on the left wing, yet *a* stands on the right of his platoon. In both cases, the line is supposed to face the same way.

INVESTITURE, in the feudal law, was the open delivery of a fief by a lord to his vassal, thus, by external proof, affording evidence of property. To use the words of Blackstone, "Investitures, in their original rise, were probably intended to demonstrate, in conquered countries, the actual possession of the lord, and that he did not grant a bare litigious right, but a peaceable and firm possession. At a time when writing was seldom practised, a mere oral gift, at a distance from the spot that was given, was not likely to be long or accurately retained in the memory of bystanders, who were very little interested in the grant." For this reason, investiture was performed by the presentation of some symbol to the person invested, as a branch of a tree, &c. In the primitive church, after the election of a bishop, and his consecration, the early Christian emperors claimed a right of confirmation. The Gothic and Lombard kings exercised the same privilege. In the French monarchy, the Merovingians affected the still greater power of direct nomination,

and their control was supported by means against which the church was wholly inadequate to contend. The estates and honours which composed the ecclesiastical temporalities, were considered to partake of the nature of fiefs, and therefore to require similar investiture from the lord. Charlemagne is said to have introduced this practice, and to have invested the newly consecrated bishop by placing a ring and crosier in his hands. Gratian, indeed, (*Distinct.* 63, cap. *Adrianus*), directly affirms that pope Adrian positively conceded to the emperor the power of electing, even to the papacy, in 774; but neither Eginhard nor any other contemporary writer mentions this fact.

The custom, however, existed, nor does it appear to have been objected to or opposed during the lapse of two centuries from his reign. The disorderly state of Italy, which succeeded the death of Charlemagne, frequently interrupted the exercise of this right by the Carolingians; but even so late as 1047, when the empire had passed to another line, Henry III. received an explicit admission of his prerogative, and repeatedly used it. The investiture in the lesser sees followed as a matter of course. Alexander II. issued a decree against lay investiture in general, which was revived by Gregory VII. (Hildebrand), who, having succeeded in annulling the prerogative of the emperors to nominate or confirm popes, sought to disjoin entirely the ecclesiastical from the civil rule. He complained loudly of the humiliation to which the church was subjected by dependence upon the patronage of laymen, and condemned with far more reason the mercenary and simoniacal exactions, which ecclesiastics suffered from temporal princes as the price of the benefices which they conferred. In the council of the Lateran in 1080, he declared that no bishop or abbot, submitting to lay investiture, should be considered a prelate. The convulsions which followed engendered the Guelf and Ghibeline factions (see *Guelf*), and deluged Italy with blood for a long series of years; for the struggle commenced by Gregory with Henry IV. was zealously continued by his successors, among whom Urban II. and Paschal II. especially distinguished themselves. It was not, however, until the papacy of Calixtus II., in 1122, that the question was terminated, as it appears, materially to the advantage of the holy see. By a concordat then arranged at Worms, Henry V. resigned for ever all pretence to invest bishops by the ring and crosier, and recognised the freedom of elections: the new bishop, however, was to receive his temporalities by the sceptre. In France, even under the papacy of Hildebrand, the right of investiture does not appear to have been made a subject of open quarrel. In spite of the protests of the holy see, the kings exercised the power, but at length relinquished the presentation of the ring and crosier, and contented themselves with conferring investiture by a written instrument, or orally, upon which they were left in peaceable possession of the power. But in England, Paschal II. was engaged in a contest little less fierce than that which he maintained with the emperor. Anselm, the primate, refused to do homage to Henry I. for his see. The king seems to have asserted an unqualified right of investiture, which the pope, who was appealed to, as unqualifiedly denied. After a protracted struggle, and continued threats of excommunication, the controversy ended in England, as it did afterwards in Germany, by compromise. Paschal offered to concede the objections against homage, provided Henry would forego the ceremony of investiture. To this he agreed.

INVOCAVIT; the first Sunday in Lent, so called because the primitive church began their worship, on

that day, with the words of the 91st Psalm, 15th verse, *Invocavit me et exaudivit eum*. It is also called *Quadragesima*, or the fortieth day, because it is forty days before Good Friday, the day when *Lent* ends.

INVOICE; an account, in writing, of the particulars of merchandise, with their value, customs, charges, &c., transmitted by one merchant to another.

INVOLUTION, in mathematics; the raising of a quantity from its root to any power assigned. Thus  $2 \times 2 \times 2 = 8$ . Here 8, the third power of 2, is found by involution. By continuing the process, we can obtain any power of 2, and so with other numbers.

IO; daughter of Inachus (according to some, of Argus Panoptes) and Peitho; according to others, of Iasus and Leucane. Jupiter fell in love with her. At first, she would not listen to his wishes; but, being enveloped by him with a thick cloud, she yielded herself to his embraces. Juno, notwithstanding, perceived the infidelity of her husband, and resolved to be revenged on both. Jupiter, to protect himself from the jealousy of Juno, changed her into a beautiful white heifer. Juno was not deceived, and begged the heifer of her husband. Approaching no evil, he granted her request; but she immediately placed it under the custody of the hundred-eyed Argus. Jupiter now regretted that he had complied with her request, but it was too late; he therefore sent Mercury to kill Argus, and set Io at liberty. This commission Mercury successfully executed, having lulled the watchful Argus to sleep by playing on the flute; but at the moment when he thought herself again at liberty, the jealous Juno afflicted her with madness, and persecuted her without a moment's rest, through the world. She sprang into the Ionian sea, reached Illyria, passed the Hæmus, went through Thrace, swam over the Thracian Bosphorus to Asia, passed through Scythia, over Caucasus, and came at length to Egypt. She found Prometheus in the Caucasian mountains, who comforted her, and showed her the way she must take. This way is described at length in the "Prometheus" of Æschylus. Her sufferings ended in Egypt. Here she regained her original form, and bore Epaphus, the son of Jupiter. At the instigation of Juno, the Curetes concealed the child, and were, in consequence, struck with lightning by Jupiter. After a long search, he found her son in Syria, and returned with him to Egypt, where she married the king, Telegonus. She was deified, and, according to some authorities, was the goddess whom the Egyptians worshipped under the name of *Isis*.

IODINE (from *ἰώδης, violaceous*, in allusion to the beautiful violet colour of its vapour) is the name of an undecomposed principle or element in chemistry. It had escaped the observation of chemists until 1812, when a manufacturer of saltpetre, at Paris, detected it in the ashes of sea-weeds, in the following manner. In evaporating the ley from these ashes, to procure the carbonate of soda which they contain, he noticed that the metallic vessels, with which he operated, were powerfully corroded, and that the corrosion was increased as the liquor became more concentrated. Having at hand, one day, a bottle of sulphuric acid, he added some of it to a portion of the mother-water, and was surprised to see a rich violet vapour disengaged; this vapour was the iodine. He at once communicated the observation to M. Clément Desormes, who set about collecting some of the vapour, and, after examining its leading properties, announced it to the royal institute of France as a new body. Its real nature was soon after unfolded through the accurate researches of

Gay-Lussac and Sir H. Davy. Its history proved singularly interesting in modifying the then prevailing theory of chemistry. Sir H. Davy had, a few years previously, promulgated the new theory of chlorine, which was still received with suspicion among chemists. The strong analogies, however, between this substance and chlorine, in their relations to combustibles,—both bodies forming compounds by uniting with them, similar to acids containing oxygen, or oxides,—were conceived to give great weight to the views of Sir H. Davy, and operated completely to overthrow the erroneous hypothesis of oxygenation, invented by Lavoisier. Its investigation, therefore, may be said to have formed a new era in chemistry. The physical properties of iodine are as follow: It is a soft, friable, opaque solid, of a bluish-black colour, with a metallic lustre, usually in scales, but sometimes in distinct crystals of the form of rhomboids or rhomboidal tables, referable to an octahedron, with a rhombic base as their primary form; its specific gravity is 4.946. It possesses an odour somewhat analogous to that of chlorine. It is a non-conductor of electricity, and possesses in an eminent degree the electrical properties of oxygen and chlorine. Iodine enters into fusion at 225° Fahr., and boils at 347°; but when moisture is present, it sublimates rapidly at a temperature considerably below 212°, and gives rise to a dense vapour of the usual violet hue. It is scarcely at all soluble in water, but is readily taken up by alcohol and ether, to which it imparts a reddish-brown colour. It extinguishes vegetable colours, but with less energy than chlorine. It is not inflammable. Its range of affinity for other bodies is very extensive; the most important compounds it forms with these we shall describe after alluding to its natural state and preparation. It exists most abundantly in the various species of fucus, which form the greatest part of the sea-weeds of our coast; it also occurs in the sponge, and in the coverings of many molluscous animals, and has been found in a great number of mineral waters, as those of Sals in Piedmont, Saratoga in New York, &c., and more recently has been detected in some silver ores from Mexico, and in an ore of zinc from Upper Silesia. But it is from the incinerated sea-weed or kelp, that the iodine, in large quantities, is obtained. As the soap-manufacturers are in the habit of obtaining their soda from kelp, iodine may be procured, very economically, from the residuums of their operation, according to the process invented by doctor Ure, which is as follows: The brown iodic liquor of the soap-boiler, or the solution of kelp from which all the crystallisable ingredients have been separated by concentration, is heated to about 230° Fahr., poured into a large stone-ware basin, and saturated with diluted sulphuric acid. When cold, the liquor is filtered through woollen cloth; and to every twelve oz. (apothecaries' weight) of it, is added 1000 grains of black oxide of manganese in powder. The mixture is put into a glass globe, or large matrass with a wide neck, over which a glass globe is inverted, and heat is applied, which causes the iodine to sublime copiously, and to condense in the upper vessel. As soon as the balloon becomes warm, another is substituted for it; and when the second becomes heated, the first is again applied. The iodine is withdrawn from the globes by a little warm water, which dissolves it very sparingly; and it is purified by undergoing a second sublimation. The test made use of for the detection of iodine in any solution, when it is suspected to be present, is starch, with which iodine has the property of uniting, and of forming with it a compound, insoluble in cold water, which is recognised with certainty by its deep blue colour. The solution should

be cold at the time of adding the starch; and, if the colour does not become apparent simply on the addition of the starch, a few drops of sulphuric acid should be cautiously added, when, if any iodine is present, the blue colour will make its appearance. This test is so exceedingly delicate, that a liquid, containing  $\frac{1}{100000}$  of its weight of iodine, receives a blue tinge from a solution of starch.

Iodine has a powerful affinity for hydrogen, which it takes from animal and vegetable substances, in the same manner as chlorine, and, uniting with it, forms hydriodic acid. The following are the methods for obtaining this acid in the gaseous and in the liquid state: Into a flask, to which a recurved tube is fitted, dipping under a jar of mercury, are introduced eight parts of iodine and one of phosphorus, and to the mixture a few drops of water are added; the water is immediately decomposed; the phosphorus, seizing its oxygen, forms phosphoric acid, while the hydrogen combines with the iodine. As there is not water present in sufficient quantity to dissolve the hydriodic acid, it passes over in the gaseous state, and is collected over the mercury. In contact with air, it smokes, or fumes, like the muriatic acid, and, like it, reddens vegetable blues. It is distinguished, however, from that acid, by the superior affinity possessed by chlorine for hydrogen, in consequence of which, if chlorine and hydriodic acid gases are mingled together, the yellow colour of the former disappears, and the violet vapour of iodine makes its appearance, which proves the decomposition of the hydriodic acid by the chlorine. If the decomposition is complete, the vessel will be wholly occupied by muriatic acid gas. To obtain the hydriodic acid in a liquid state, we have only to conduct the gas through water, until it is fully charged with it; or it may be obtained by transmitting a current of sulphureted hydrogen gas through water in which iodine, in fine powder, is suspended. The iodine, from a greater affinity for hydrogen than the sulphur possesses, decomposes the sulphureted hydrogen; and hence sulphur is set free, and hydriodic acid produced. The constitution of hydriodic acid is,

	By Volume.	By Weight.
Iodine . . . .	50	124
Hydrogen . . . .	50	1
	100	125

The solution of hydriodic acid is easily decomposed. Thus, on exposure for a few hours to the air, the oxygen of the atmosphere forms water with the hydrogen of the acid, and liberates the iodine. Nitric and sulphuric acids likewise decompose it by yielding oxygen, the former being converted into nitrous and the latter into sulphurous acid. The free iodine becomes obvious on the application of the above-mentioned test. The compounds of hydriodic acid with the salifiable bases may be easily formed, either by direct combination, or by acting on the basis in water with iodine. Sulphurous and muriatic acids, as well as sulphureted hydrogen, produce no change on the hydriodates, at the usual temperature of the air; but chlorine, nitric, and concentrated sulphuric acid, instantly decompose them, and separate the iodine. The hydriodates of potash and soda are the most interesting of their number, because they are the chief sources of iodine in nature. The latter salt is probably the one which affords the iodine obtained from kelp; while it is believed, that it is the hydriodate of potash, which is most generally found in mineral springs. Hence the necessity of adding sulphuric acid to the residual liquor of the soap-boiler, in order to procure iodine, which requires to be separated from its combination

with the alkali to which it is united, in the condition of hydriodic acid; and peroxide of manganese is also added, in order to facilitate the decomposition of the hydriodic acid.

Iodine forms acids also by uniting with oxygen and with chlorine. When it is brought into contact with protoxide of chlorine, immediate action ensues; the chlorine of the protoxide unites with one portion of iodine, and its oxygen with another, forming two compounds,—a volatile orange-coloured matter, the chloriodic acid, and a white solid substance, which is iodic acid. Iodic acid acts powerfully on inflammable substances. With charcoal, sulphur, sugar, and similar combustibles, it forms mixtures which detonate when heated. It enters into combination with metallic oxides, giving rise to salts called *iodates*. These compounds, like the chlorates, yield pure oxygen by heat, and deflagrate when thrown on burning charcoal. Iodic acid is decomposed by sulphurous, phosphorous, and hydriodic acids, and by sulphureted hydrogen. Iodine, in each case, is set at liberty, and may be detected, as usual, by starch. Chloriodic acid, which is also formed by simply immersing dry iodine in chlorine gas, deliquesces in the open air, and dissolves very freely in water. Its solution is very sour to the taste; and it reddens vegetable blues, but afterwards destroys them. It does not unite with alkaline bases; in which respect it wants one of the characteristics of an acid, and has hence been called by Gay-Lussac a *chloride of iodine*. Iodine unites with nitrogen, forming a dark powder, which is characterized, like chloride of nitrogen, by its explosive property. In order to form it, iodine is put into a solution of ammonia; the alkali is decomposed; its elements unite with different portions of iodine, and thus cause the formation of hydriodic acid and iodide of nitrogen. Iodine forms, with sulphur, a feeble compound, of a grayish-black colour. With phosphorus, also, it combines with great rapidity at common temperatures, attended with the emergence of heat. It manifests little disposition to combine with metallic oxides; but it has a strong attraction for the pure metals, producing compounds which are called *iodurets*, or *iodides*. The iodides of lead, copper, bismuth, silver, and mercury, are insoluble in water, while the iodides of the very oxidizable metals are soluble in that liquid. If we mix a hydriodate with the metallic solutions, all the metals which do not decompose water will give precipitates, while those which decompose that liquid will give none. Iodine, besides being employed for philosophical illustration, is used in the arts, for pigments, dyes, and medicine. The proto-ioduret of mercury is used in England as a substitute for vermilion, in the preparation of paper-hangings; and a compound of hydriodate of potassa 65, iodate of potassa 2, and ioduret of mercury 33, is employed in printing calico. The tincture of iodine, 48 grs. to 1 oz. of alcohol, is a powerful remedy in the goitre and other glandular diseases; but it is so violent in its action on the system as to require great caution in its administration. The hydriodate of potash, or of soda, is also applied to medical uses; and it is inferred, that the efficacy of many mineral springs, in certain diseases, is owing to the presence of one or the other of these salts.

IOLAUS. See *Protesilaus*.

IOLÉ. See *Hercules*.

IOLITE, CORDIERITE, or DICHROITE, is an earthy mineral, commonly massive, though sometimes crystallized in six or twelve-sided prisms, with indistinct cleavages, parallel to the sides of a six-sided prism, which is considered as its primary form; lustre, vitreous; colour, various shades of blue, generally inclining to black; streak, white; transparent or translucent; blue, if viewed in the direction of

the axis; yellowish gray, perpendicular to it; hardness, the same as that of quartz; specific gravity, 2.583. It consists, according to Stromeyer, of

Silica, . . . . .	69.534
Alumina, . . . . .	31.730
Magnesia, . . . . .	11.376
Oxide of Iron, . . . . .	5.696
Oxide of manganese, . . . . .	0.702
Water, or loss, . . . . .	1.649

Before the blowpipe, it melts in a good heat, but with difficulty, and only on its edges, into a glass not inferior to the mineral, either in colour or transparency. It occurs in aggregated crystals, with garnet, quartz, &c., at Cabo de Gata in Spain. A variety found in Bavaria, at Bodenmais, which is generally massive, resembling quartz, and imbedded in iron pyrites, has been called *pelion*. Handsome blue crystals of this species, found at Orijerfvi in Finland, have been called *steinheilite*, in honour of count Steinheil. The *sapphire d'eau* of jewellers is a transparent variety of the present species from Ceylon.

ION; 1. a son of Xuthus and Creusa, daughter of Erechtheus, who married Helice, the daughter of Selinus, king of Ægiale. He succeeded to the throne of his father-in-law, and built a city, which he called *Helice*, on account of his wife. His subjects, from him, received the name of *Ionians*, and the country that of *Ionis*. (See *Ionians*) 2. A tragic poet of Chios, who flourished about the eighty-second Olympiad. His tragedies were represented at Athens, where they met with universal applause. He is mentioned and greatly commended by Aristophanes and Athenæus, &c. 3. A native of Ephesus introduced in Plato's dialogues as reasoning with Socrates.

IONIA. See *Iolmkill*.

IONIA; the ancient name of Achæia (hence the *Ionian* sea and *Ionian* islands). By *Ionis* is generally understood that district of Asia Minor, where the Ionians from Attica settled, about 1050 B. C. This beautiful and fertile country extended from the river Hermus to the Mæander, along the shore of the Ægean sea, opposite the islands of Samos and Chios, and was bounded by Caria, Æolia, and Lydia. Commerce, navigation, and agriculture early rendered it wealthy and flourishing, as is proved by the great number of populous cities it contained, among which the most important were Ephesus (the chief place), Smyrna, Clazomenæ, Erythra, Colophon, and Miletus. These free cities formed the Ionian league, but Cræsus, and afterwards Cyrus, made them tributaries. They remained subject to the Persians until they recovered their independence by the assistance of the Athenians and Lacedæmonians, after having previously made an unsuccessful attempt, during the reign of Darius Hystaspes. They were again subjected, and again delivered by Alexander the Great. *Ionis*, at a later period, became a Roman province, and was totally devastated by the Saracens, so that few vestiges of its ancient civilization remain. The *Ionians* were considered effeminate and voluptuous, but, at the same time, highly amiable. Their dialect partook of their character. (See *Ionian Dialect*.) The arts and sciences flourished in this happy country, particularly those which contribute to embellish life. The Asiatic Greeks became the teachers and examples of the European Greeks. Homer the poet, Apelles and Parrhasius the painters, were Ionians. The Ionic column proves the delicacy of their taste. See *Architecture*, *Ionian Philosophy*, and *Ionians*.

IONIAN DIALECT; one of the Greek dialects, the softest of all, on account of the large proportion of the vowels to the consonants (see the article *I.*)

romans), which was particularly spoken in the Greek colonies in Asia Minor and on the islands of the Archipelago. It is divided into the old and new. In the former, Homer and Hesiod wrote. It originally differed little, or not at all, from the old Attic. The new Ionian originated after the Ionians had more intercourse with the other tribes, and planted colonies. Anacreon, Herodotus, and Hippocrates wrote in this dialect. See *Greek Language*, under the head of *Greece and Dialect*.

IONIAN ISLANDS; a republic in the south of Europe, under the protection of Great Britain, situated in the Ionian sea, along the western coast of Greece and Albania. The state is often called the *Republic of the Seven Islands*, on account of the seven chief islands of which it is composed, viz., Corfu, Paxos, Santa Maura, Thiaki or Ithaca, and Cephalonia, lying west of the gulf of Lepanto; Zante, near the western shore of the Morea; and Cerigo, to the south-east of the same peninsula. The other islands and islets of this little state are Merlera, Fano, Samouraki, Anti-Paxos, Calamos, Meganesi, and Cerigotto, which is the most southern and most eastern point of the republic, in 35° 50' lat. N., and 23° 17' lon. E. Merlera, in 39° 57' lat. N., is the most northern, and Fano, in 19° lon. E., the most western point. Most of the inhabitants of the Ionian islands are of Greek origin. A census, in 1814, gave a population of 218,000: at present, it amounts to about 227,000, of whom about 8000 are Italians, and 7000 Jews. There are also some English there. The inhabitants are in general superstitious, and their morals are lax. Until of late, the language spoken here was a corrupt Italian, but modern Greek now prevails. The English and Greek inhabitants have little intercourse, notwithstanding the efforts of the English government. In 1828, there were twenty-nine schools of mutual instruction, a college, and a university, founded in 1823.

The coasts of the islands are rugged, the surface uneven, containing a number of barren rocks and some high hills, interspersed with fertile plains and valleys. The climate is very mild, but subject to sudden changes. The productions are corn, vines, olives, currants, cotton, honey, wax, &c. Vines and olives form the chief source of income to the inhabitants. In 1825, the exports amounted to nearly £150,000. The currants and small dried grapes are exported in large quantities. Since 1815, this state has formed an aristocratic government, under the name of the *United Ionian Islands*, under the protection of Great Britain, and entirely dependent on her. A constitution was granted by Great Britain, in 1817. There is a British high-commissioner at Corfu, the capital of the state, and Great Britain has a right to occupy the fortresses, and keep garrisons. The high commissioner convokes the legislative assembly, appoints the governors of the different islands, and commands the forces. The legislative assembly consists of forty members, and holds its sessions at Corfu. Five senators, chosen by the legislative assembly from their own number, and a president, appointed by the commissioner, for five years, form the senate. The civil law is the law of the land. Revenue, about £150,000; expenditure for the force maintained by Great Britain (6400 men, among whom are four regiments of natives), £100,000.

These islands were inhabited at an early period, and formed small states in the most flourishing period of Greece. They were reduced by Alexander the Great, at a later period by the Romans, and they afterwards formed part of the Byzantine empire. The kings of Naples obtained possession, in the thirteenth century, of Corfu and other islands, but, in

the fourteenth century, the Venetians, then the masters of the Adriatic sea, occupied all the Seven Islands. Corfu placed herself under the protection of Venice, in 1386, and the other islands followed her example. Venice left the government in its former state, merely sending out *provveditori* as heads of the administration. The claims of Naples were extinguished by purchase, and Venice remained in possession of the islands, in spite of the repeated attacks of the Turks, until the republic of Venice was itself dissolved, in 1797. In 1799, the Russians and Turks conquered them; and the emperor Paul, by a ukase of March 21, 1800, declared them a state, under the name of the *Republic of the Seven United Islands*, forming an aristocracy under the protection of Turkey. In 1803, Russia granted a new constitution. In 1807, they were incorporated with the great empire of France; but the French were able to maintain only Corfu. Nov. 5, 1815, it was agreed between Russia and Great Britain (later also Austria), that the islands should form a republic, under the name of the *United State of the Ionian Islands*, and under the exclusive protection of Great Britain. In April, 1819, Great Britain agreed to cede to the Porte the city of Parga, on the continent, which had so long maintained itself against Ali Pacha (q. v.). The greater part of the Pargiots, in despair, emigrated to the Ionian islands. (See *Parga*.) The commercial flag of the Ionian Islands is acknowledged as the flag of an independent nation. See the works of Gell, Dodwell, Hughes, Mustoxodi, and Kendrik; also, *Essay on the Islands of Corfu, Leucadia, Cephalonia, &c.*, by W. Goodisson (London, 1822); *Antiquities of Ionis*, published by the society of Dilettanti, London.

IONIAN ORDER. See *Architecture*.

IONIAN PHILOSOPHY. As Grecian civilization was first developed among the Ionians (see *Ionians and Ionia*), Grecian philosophy also originated among them. The Ionian philosophy started with the question respecting the primitive elements of the world. To the Ionian school (*ai Iōniōi*) belong Thales, Anaximander, Pherecydes, and, in some points, Anaximenes. (See *Philosophy*, and consult Bouterwek, *De primis Phil. Græc. Decretis Physicis*, in the second volume of the *Comm. Soc. Goett.* 1811; Ritter, *Geschichte der Ionischen Philosophie*, Berlin, 1821, and *Geschichte der Philosophie*, volume 1st, by the same, Hamburg, 1829). In modern times, the Ionian philosophy has been revived, in connexion with the atomic system, by Berigard, Magnusus, Sennert, and Gassendi.

IONIAN SEA; ancient name of that part of the Mediterranean which lies between the south part of Italy and Greece.

IONIANS; a tribe of Greeks, deriving its name from Ion (q. v.). They first lived in the Peloponnesus, on the borders of the gulf of Corinth, where they built twelve cities, celebrated for their manufactures and commerce. The Achæans, being pressed by the Heraclides and Dorians, united themselves with them, and the country became insufficient for both people; the Ionians therefore emigrated to Attica, whence Neleus led a colony to Asia. (See *Ionia*.) Those who had remained in Attica were mingled with other tribes, and the Asiatic Ionians alone retained the name.

IONIC FOOT consists of four syllables, two short and two long. If the two short syllables are in the beginning (— — — —), it is called *ionicus minor*: if the two short syllables follow (— — — —), it is called *ionicus major*. Horace used the former.

IOTA; the Greek name for *i*. See *I*.

IPECACUANHA, according to the latest authorities, is the product of two different plants, both

natives of South America. The gray is the root of a species of *richardia*; the other, that of the *cephælis ipecacuanha*. The two roots, however, do not differ in their medicinal properties, and they are much employed indiscriminately. It was first brought to Europe towards the middle of the seventeenth century; but was not generally used till about the year 1686, when it was introduced, under the patronage of Louis XIV. Its taste is bitter and acrid, covering the tongue with a kind of mucilage. It is one of the safest and mildest emetics with which we are acquainted, and is administered as a powder, in the tincture, or infused in wine. It is also less injurious, if it does not operate as an emetic, than antimony, from its not disturbing the bowels as that does.

**IPHICRATES**; a famous Athenian military commander, in the fourth century before the Christian era. He was born in obscurity, but raised himself to eminence in his profession, by his courage and talents, early in life. In the war of Corinth, 395 B. C., he opposed, with success, Agesilaus, the warlike king of Sparta. He afterwards commanded a body of auxiliary troops, in the service of Artaxerxes, king of Persia, in an expedition to Egypt; and, in 368 B. C., he relieved Sparta, when invaded by the Theban general Epaminondas. In the social war, he was one of the commanders of the fleet fitted out by the Athenians, for the recovery of Byzantium, when, being accused of treachery by one of his colleagues, he defended himself with such spirit, that he was acquitted by his volatile countrymen; but, though he lived to a great age, he did not again engage in active service. In the early part of his career, he restored to his dominions Seuthes, king of Thrace, whose daughter he married. Iphicrates was a strict observer of discipline, and was the author of some important improvements in the arms and accoutrements of the Athenian soldiery. He was accustomed always to fortify his camp in the field, even in a friendly country; and, when once asked why he took so much trouble, he answered, "Because, if, contrary to probability, I should be attacked, I may not be obliged to make the disgraceful excuse, that I did not expect it."

**IPHIGENIA**, daughter of Agamemnon and Clytemnestra (according to some, an illegitimate daughter of Theseus and Helen, adopted by Clytemnestra in childhood), was to have been sacrificed to Diana, at the advice of the prophet Calchas, when the goddess, enraged with Agamemnon, because he had slain, in hunting, her consecrated hind, detained the Greek fleet in Aulis by a calm. Under the pretence that she was to be married to Achilles, Iphigenia was taken from her mother, and led to the altar. But, in the moment when the priest was about to give the death blow, Iphigenia disappeared, and, in her stead, a beautiful hind was substituted, whose blood gushed out on the altar. Diana had relented, and conveyed her in a cloud to Tauris, where she became the priestess of the goddess. Conformably with the cruel law of the country, she was obliged to sacrifice every Greek that landed there. Her brother Orestes, coming thither on his wanderings, in despair at the murder of his mother, and wishing to take away the statues of Diana, was likewise condemned to be sacrificed to the goddess. A recognition took place in the temple, and, after deliberating on the means of escape, Orestes succeeded in removing Iphigenia and the statues of Diana. Some nations maintained, that they derived the worship of Diana of Tauris from Iphigenia. She herself is said to have arrived at the island of Leuca, and, after being endowed with immortal youth, and the name of Orilochia, to have married the shade of Achilles. Pausanias says that her grave was shown at Megara. In two famous

operas by Gluck, and Goethe's masterpiece, *Iphigenia auf Tauris* (Iphigenia at Tauris), Iphigenia is the leading character.

**IPHITUS**; king of Elis, in Greece, the son of Praxionidas, and grandson of Oxylius, measurable as the institutor of the famous Olympic games. They are said to have been originally celebrated by Pelops, or, according to some, by Hercules, in honour of Jupiter; and, after being neglected for several ages, they were restored or re-established by Iphitus. Controversies have arisen as to the age in which the prince lived. Some chronologers place him 884 B. C.; but Sir Isaac Newton has shown that he probably lived a century later, and that the first games of his institution were held 766 B. C.; from which period they were continued, without interruption, for several centuries. See *Olympic Games*.

**IPSARA**. See *Psara*.

**IPSILANTI**. See *Ypsilanti*.

**IRAK ADJEMI**. See *Persia*.

**IRAK ARABI**; the ancient Babylonia and Chaldaea.

**IRAN**. See *Persia*.

**IRELAND**; a large and fertile island of Europe, the second in extent of the British islands, is situated in the Atlantic ocean, between lon. 5° 19' and 10° 28' W., and lat. 51° 15' and 55° 23' N. It is separated from Great Britain by the Irish channel or St. George's channel, and the North channel. The channels vary much in breadth. The least breadth is between the Mull of Kintyre, in Argyleshire, and Torhead, in the county of Antrim, the distance between these two places being about fourteen miles. The nearest land to Ireland on the west is America, on the south Galicia, in Spain; and on the north the Hebrides.

*History*.—The beginning of the history of Ireland is enveloped in fable. The historians of the country speak of Greek and Phœnician colonies, give lists of kings, &c., for which there is no historical foundation. The vernacular language of the Irish proves that they are a part of the great Celtic race, which was once spread all over Western Europe. (See *Gaul*.) An Irish manuscript has been found more ancient than the tenth century. The oldest and most authentic Irish records were written between the tenth and twelfth centuries; some of them go back, with some consistency, as far as the Christian era; but there is no evidence that the Irish had the use of letters before the middle of the fifth century, when Christianity and Christian literature were introduced by St. Patrick. The new faith did not flourish till a century later, when St. Columba erected monasteries. In the eighth and ninth centuries, the scholars of Ireland were among the most distinguished at the courts of the Saxon kings, and of Charlemagne. But when the Northmen commenced their descents on the coast, the ecclesiastics took to flight; and it is evident from the condition of the people at a later period that the learning of the Irish clergy never extended beyond the walls of the monasteries. Divided since a number of barbarous and hostile chiefs, Ireland had been for a long time torn by internal wars, and for nearly two centuries, ravaged by the Danes, when, in the beginning of the eleventh century, Brian Borroimhi, or Borroimh (the Conqueror), united the greater part of the island under his sceptre, restored public tranquillity, and expelled the northern invaders. In 1155, Henry II, king of England, obtained a bull from Adrian IV., granting him the possession of Ireland. In 1169, English troops under the earl of Pembroke (Strongbow) landed in the country, which was soon partially reduced by the invaders, aided by the mutual hostilities and jealousies of the native chiefs. The country over, which the English

actually ruled included the four counties of Dublin, Meath, Louth, and Kildare, and was called the *pale*. In the rest of the island, the native chiefs still maintained their independence. In 1310, Edward Bruce, brother of the king of Scotland, landed in Ireland, at the head of a Scotch force, and caused himself to be crowned king of the island; but, not being vigorously supported by the Irish, who had invited his assistance, he was defeated by the English, and the Scotch were obliged to return without accomplishing any thing. There still remained one independent prince, in the province of Ulster, whose daughter and heir having been married to the duke of Clarence, son of Edward III., that province came into the hands of the English in 1361. A parliament, held at Kilkenny in 1367, forbade intermarriages with the Irish, the use of their language, &c., under severe penalties, and thus contributed to widen the distinction between the two nations, which it should have been the policy of the English government to amalgamate. In the reign of Henry VI., Richard, duke of York, was appointed chief governor; and an attachment to his descendants continued to influence the Anglo-Irish during the reign of Henry VII., as appears in the affair of Lambert Simnel. In his reign (1495) was passed *Poyning's act* (so called from Sir Edward Poyning, lord-deputy of Ireland), which provided that all former laws passed in England should be in force in Ireland, and that no Irish parliament should be held without previously stating the reasons on account of which it was to be summoned, and the laws which it was intended to enact. When Henry VIII., in the sixteenth century, embraced the reformation, the Irish continued to adhere to the Catholic religion. But, in 1541, Henry received from the Irish parliament the title of *king of Ireland*, instead of *lord*, which he had before borne, as a vassal of the pope. The monasteries were suppressed, the tribute to the papal see abolished, and, to reward the chieftains for their submission, O'Neil, O'Brien, and De Burgo were created earls; they were the oldest peers of Irish descent. Under Edward VI., the deputy proposed to the Irish parliament the adoption of the reformation. Three archbishops and seventeen bishops left the assembly; most of the clergy fled the country, and those of the lower clergy who remained, being deprived of their incomes, lived on the charity of their parishioners. Elizabeth, in 1560, caused the measures adopted in the reign of Mary to be abrogated, and replaced every thing on its former footing. She endeavoured to improve the condition of Ireland, and employed able men to effect her purposes, yet her reign was marked by a series of risings, which finally terminated in a general war against England, usually called the *rebellion*. O'Neil, earl of Tyrone, instigated by the pope, and supported by the Spaniards, was the leader in this war, which, though successfully begun, ended with the reduction of the whole island (1603). In 1613, the first national parliament was held in Ireland; but of 226 members of the house of commons, 125 were Protestants, and the upper house consisted of twenty-five Protestant bishops and twenty-five temporal lords, of whom but few were Catholics. The reign of James (1603–25) was, on the whole, favourable to Ireland; the arbitrary power of some of the chieftains was restrained, the administration of justice improved, &c.; but religious troubles were occasioned by the disabilities to which the Catholics were subjected. On the accession of Charles I., Wentworth, afterwards earl Strafford, was appointed lord-lieutenant; and his administration was beneficial to the country. But the republican inclinations of the English residents, the hate which existed between them and the Irish Catholics, the influence of the Irish clergy, who

were educated in foreign countries, with other circumstances, led to an attempt to shake off the English yoke. Dr Lingard says of this insurrection, that it has been usual for writers to paint the atrocities of the natives and to omit those of their opponents, but that revolting barbarities are equally recorded of both, and that if among the one there were monsters who thirsted for blood, there were among the other those who had long been accustomed to deem the life of a mere Irishman beneath their notice. After the death of Charles, Cromwell was appointed lieutenant of Ireland, and, with his usual energy and promptitude, but with great cruelty, soon reduced the whole country. All the possessions of the Catholics were confiscated, about 20,000 Irish were sold as slaves in America, and 40,000 entered into foreign service, to escape the severity of the conqueror. Charles II. restored the fourth part of the confiscated estates to the Irish, and James II. appointed Tyrconnel, a Catholic, lord-lieutenant of Ireland, and filled the parliament with Catholics.

But the sudden deposition of James from the English throne changed the face of matters. Almost at the same time that information was received that William had ascended the English throne, and meant immediately to send troops and supplies into Ireland, intelligence came that James had landed in Munster with an army. On the 24th of March 1689, he entered Dublin. His promises of protection to the Protestants were rendered very suspicious, by the solemn procession with which the Catholic clergy welcomed him into Dublin, and, in a very short time, were unequivocally proved to be insincere. As the Protestant strength lay chiefly in the north of Ireland, James resolved to direct his march thither. Londonderry was to be first reduced. In this city Lundy commanded, a man suspected of attachment to James, but to whom William, in the midst of his embarrassments, had been obliged to commit this important place. The suspicion that attached to him was too well founded. He refused to defend the town; and had it not been for the skill and intrepidity of George Walker, a clergyman, James would instantly have gained admittance into it. The inhabitants, encouraged by him, resolved to defend the town, and elected Walker, and a Major Baker, their governors. The garrison consisted of 7361 men; but there was not one well mounted cannon, no engineer, no person who possessed any considerable degree of military skill. The fortifications too, originally not strong, were by no means in a good state, the stores were few; and besides the garrison, there were 30,000 people, who could be of little or no use, to maintain. Under such circumstances, they determined to defend their town against James's army, consisting of 20,000 men, well equipped in every respect, prepared for the siege, and led by him in person. It is not to be supposed that Walker and his brave associates were qualified to defend the town according to the rules of military art. They depended solely on zeal, perseverance, and courage. Their sallies were frequent, fierce, and destructive to the besiegers; and so confident were they in themselves, that they always kept the gates open, in order that they might sally forth whenever an opportunity occurred; and when James's army battered the walls, they told them that was useless, as they might enter by the gates if they were so disposed. The prospect of reducing this place, so defended, appeared to James so distant, that after having continued his assaults for eleven days, he returned to Dublin, leaving his forces with orders to continue the siege. From force, there seemed now no chance of gaining the town. The besiegers, therefore, resolved to wait patiently till famine forced it to surrender. Of the approach of

this, the inhabitants were not unapprehensive; but they trusted that supplies of forces and provisions would speedily arrive from England; and, in the mean time, the clergy in the town, both of the establishment and belonging to the dissenters, by daily addressing the people in the cathedral, kept up and even increased their determination never to yield.

The town had been first assailed on the 17th of April. On the 30th of July, three ships were seen in Loch Foyle, part of some which had before appeared there. On these vessels the eyes both of the besiegers and besieged were anxiously fixed. The attempt to approach the town was extremely difficult and hazardous; and the besiegers now did every thing in their power to increase the difficulty and danger. Where the lake narrowed, its shores were lined with batteries, and a boom formed as strong as it could be made, was stretched across this narrow part. This boom consequently must be broken, before the vessels could possibly approach. One of them came near it. All eyes were fixed on the event. Sailing with considerable velocity, she broke the boom. The besieged were almost intoxicated with joy, when the next moment their joy was changed to despair, on observing the vessel on shore, in consequence of the rebound given her in breaking the boom. The next moment the recoil of her guns, which were fired on the besiegers as they attempted to take possession of her, again set her afloat. The garrison were now relieved from famine; and as on famine alone the besieged had trusted for success, they immediately retired, having lost 8000 men. Of the 7360 of which the garrison consisted, 4300 survived; but a large portion of these were incapable of service.

As soon as the Protestants of Enniskillen learned the issue of the siege, they went in pursuit of the enemy, and not only harassed them, but by their rapid excursions, struck terror even to the capital. At length three different armies were sent against them. Two of these they defeated, and the third, under the duke of Berwick, they obliged to retreat.

The Protestants had long looked for effectual succours from England. At length they arrived under Schomberg and Solmes. From Bangor, in the county of Down, where Schomberg landed, he advanced to Dundalk, taking possession of Belfast, Antrim, Carrickfergus, &c. on his route. His encampment at Dundalk was very injudiciously chosen in a low and damp spot, by which sickness attacked his troops. Against him, thus encamped, the army of James marched, commanded by him in person. The situation of Schomberg, though unhealthy, was strong; so that James, after making a show of immediate and general attack, retired to Ardee. The people of England having indulged in great hopes from the operations of Schomberg's army, were loud in their expressions of disappointment and indignation, when they learned that his plan seemed rather defensive than offensive; and William resolved, in order to pacify the people, to go himself into Ireland; and he accordingly landed at Carrickfergus on the 14th of June, 1690.

Having put himself at the head of his forces, the army of James retired before him to the southern side of the Boyne, near Drogheda, where it halted; James, who had joined it from Dublin, declaring his resolution to try the fate of a battle. The hostile armies were nearly equal, that of James consisting of 33,000 men, and that of William of 36,000 men. The army of the former was composed of French and Irish; that of William of Dutch, Danes, and other foreigners, among whom were some Huguenots, and English and Irish; the last were principally Inniskillen Protestants. The position of James's army

was strong; but William, after having reconnoitred it, resolved to cross the Boyne and attack him. For this purpose, he formed his army into three divisions, with orders to pass the river in three different places. The right wing crossed early in the morning of the 1st of July, 1690, without opposition, and, by their manoeuvres, soon put to flight those of the enemy with whom they had to contend. The passage of the centre division was not effected so easily; and, after it was effected, the Huguenots were thrown into disorder. To retrieve which, Schomberg put himself at their head, and being taken prisoner, he was accidentally killed by the fire of his own troops. Nearly at the same time fell George Walker, the heroic defender of Londonderry. The object of William himself, who headed the third division, was, after crossing the river, to take the enemy in flank; but the English cavalry under his immediate command, could not withstand the impetuous attack of their opponents, and were forced to give way. In this dilemma, the Enniskilleners immediately advanced, charged the enemy in the most brave manner, and thus afforded time for the cavalry to rally. The infantry of James now gave way; and James himself, alarmed at his danger, put himself at the head of a regiment of cavalry, and gained the pass of Duleek, three miles to the south of the field of battle. The rest of his forces having also passed through this defile, formed again, and effected their retreat in good order. The loss of the vanquished is said to have been 1500, and that of the victors 500.

James fled with such rapidity, that he reached Dublin that night. He stopped there a very short time; and after having advised his partisans to submit to William, he continued his route, and embarked at Waterford for France. His army also retreated by Dublin; but they directed their march towards Athlone and Limerick.

William did not at first pursue the defeated army; but having received the submission of the garrison of Drogheda, he advanced slowly to the south, and encamped about two miles from Dublin. A proclamation was immediately issued, promising pardon and protection to the lower orders of men who had remained at home, or should return thither, and give up their arms; but expressly excluding from pardon the leaders of the rebellion. Commissioners were also appointed to seize all forfeitures arising from the rebellion.

As the enemy's forces had retreated to Athlone and Limerick, it became necessary to take measures for following and reducing them. Accordingly, after William had permitted his army to rest a short time, he detached ten regiments of infantry, and 600 of horse, towards Athlone, while he himself marched southward with a large force. Athlone was first attacked; but William's troops being repulsed, their commander judged it prudent to give up the enterprise, and to march to join the king. The great object of the monarch was the reduction of Limerick. He began his approaches to this city, which was very strong, on the 9th of August. The garrison was commanded by Boileau, a Frenchman, who took every measure that skill and experience could suggest for the defence of the place. One of his first enterprises was to intercept an escort, and succeeding in this, he gave fresh spirit to his troops, and an earnest to William of the difficulties he might expect to encounter. The king, however, was naturally of a temper not easily daunted or dispirited. He proceeded in his plans, and, on the 18th of August, was enabled to open his batteries. On the 27th, having effected a breach, an assault was ordered; but after this attempt had been carried

on for the space of three hours, William was obliged to retreat, with a loss of 500 killed and 1000 wounded; and soon afterwards he ordered the siege to be raised, and his army to retreat to Clonmel. Thence he himself proceeded to Waterford, and embarked for England. On his departure, the command of the forces was left to count Solmes and Ginckle, and the care of the civil government to two lords justices.

The earl of Marlborough had, before William raised the siege of Limerick, sailed from Portsmouth with 5000 men; and, landing near Cork, he reduced this place and Kinsale. This event, so prejudicial to the cause of James, was almost immediately followed by the departure of Boileau and his French soldiers from Limerick, between whom and the Irish there had long been much jealousy. The Irish were not, however, dispirited by these events. On the contrary, they prepared for an attack on the garrison at Mullingar, and, for this purpose, had collected forage for 5000 cavalry for five days at Athlone. Ginckle, on learning this, resolved to anticipate the attack, and, marching at the head of 3000 men from Mullingar, he attacked a considerable body of the Irish, who were encamped at Ballymore. The attack succeeded; the enemy fled; but, rallying at a place called Grenoge, they again gave battle, and were again defeated, and thrown into complete disorder. By this defeat, their plan of offensive operations against the English garrisons was frustrated.

The partisans of James would probably have given way to despair, had not their hopes been kept up by the promise of supplies from France; but only officers came, and among them Saint Ruth, who was empowered by James to take the command of all his troops in Ireland. This general, after having learnt the number of the forces which he was to command, and of those by which he would be opposed, deemed it prudent to act solely on the defensive; and he therefore strengthened his posts on the west side of the Shannon, while with his main army he took his station behind Athlone. Against Saint Ruth thus situated, Ginckle resolved to commence offensive operations. On the 18th of June, he came in sight of the town; a breach was soon made in the wall of what is called the English town, and that part was taken by storm; but it seemed impossible to reach the Irish town, the bridge being broken down, and the Shannon being here extremely deep, and at the same time very narrow. Ginckle, under these circumstances, twice attempted to repair the bridge, but the works were destroyed. His officers and troops, instead of being discouraged, were eager to ford the river, notwithstanding the obstacles and dangers to which they would be thus exposed; and the general giving way to their impetuosity, they rushed into the stream, gained the opposite shore, and in spite of the enemy's incessant fire, in half an hour were masters of the town. This disaster increased the mutual hatred of the Irish and French; and of it, and the hatred thus increased, Ginckle endeavoured to take advantage, by issuing a proclamation, offering pardon to those who would desert James. This offer, however, produced little effect; and it was evident that the cause must be entirely decided by force of arms.

Saint Ruth, immediately on the reduction of Athlone, retired with his army, which consisted of 25,000 men, to the heights of Kilcommedeen. Here he took up a strong position, and awaited the approach of Ginckle, who was not slow in following him, notwithstanding his army consisted of only 18,000 men. This inferiority, however, was amply compensated by the spirit by which his soldiers were animated. Indeed a most bloody contest was about

to take place. The first effort of Ginckle was to force a pass on the right of the enemy; and this having been effected, his whole left wing advanced through it; and attacked the right of the Irish. The contest was severely contended; and the Irish, even after they were obliged to give way, retired only to flank their assailants in their turn. Saint Ruth, as soon as he was informed of the attack on his right, drew great part of his cavalry from his left to support it. Advantage was immediately taken of this, and orders given to force the pass of Aghrim castle, on the left of the enemy by the cavalry, while the infantry made a movement to support this attack. The latter charging with impetuosity, the enemy designedly gave way, and the assailants, pursuing too far, were overpowered by a charge on the front and flank at the same time. The cavalry, however, had succeeded in their object, which induced Saint Ruth to make them the principal object of his attack. But, while he was giving orders to that effect, he was slain by a cannon ball. The disputes between the French and Irish now produced the most fatal results; for Saarfild, the Irish general, being totally unacquainted with Saint Ruth's plans, was unable to follow them up, and, before he could decide in what manner to act, the English were victorious. Their loss was only 700 killed, and 1000 wounded, whereas the Irish lost 7000, besides 450 prisoners, and all their cannon, ammunition, &c. Allowing his troops a few days' repose, Ginckle marched against Galway, which soon surrendered, on condition that its garrison should be permitted to march to Limerick. The terms in other respects were liberal as well as politic; for, as soon as they were known, considerable numbers deserted the cause of James. Still, however, his partisans were numerous, and such as remained firm, were animated by a most determined spirit of resistance.

No place of consequence now remained to James except Limerick, and thither Ginckle directed his march. Recollecting, however, the ill success of his master before this place, he resolved to proceed with the utmost caution. He took measures to prevent the garrison receiving supplies by sea, and to secure his own communication with Kerry, in case he should be obliged to take up his winter quarters there. As the garrison was equal in numbers to his own army, it would have been madness to have attempted to have taken the town by assault. Instead, therefore, of wasting his time in making breaches in the walls, he resolved to cut off their provisions, by cutting them off from the county of Clare, whence they were drawn. This enterprise was successfully performed, to the surprise and consternation of the Irish, who, when they saw the batteries dismounted, thought that the siege was about to be raised. The next object of the general was to gain possession of Thomond Bridge and King's Island, which lie to the north of what is called the English Town. The Shannon was crossed, the works that protected the bridge were approached and stormed, and, after a desperate resistance, the English made a lodgment within ten yards of it. Ginckle was surprised at his own success; but a general engagement which the enemy ought to have hazarded on this occasion, was prevented by the disputes between the Irish and the French. This dissension, together with the success of the English, produced an offer to capitulate; and Ginckle here, as at Athlone, gave the most liberal terms. In a few days after Limerick was thus reduced, a French fleet appeared in the Shannon, with such supplies of troops, &c. as must have rendered it impossible, if they had got into the city, to have taken it.

The articles of Limerick, as they are called, that is, the terms on which this city, and all the other

posts in possession of the adherents of James, were surrendered, were in substance as follows: "That the Catholics should enjoy such privileges in the exercise of their religion, as were consistent with law, or such as they had enjoyed in the reign of Charles II.: That their Majesties, as soon as their affairs would permit, should summon a parliament, and endeavour to procure from it such further security as might preserve them from being troubled on account of their religion: That all the Irish in the kingdom in the service of James, should be pardoned, and exempted from all actions for debt, on account of plunder committed by them in the course of the war: That they should be reinstated in their property, and in their rights and titles, as soon as they took the oath of allegiance, enjoined by an act of the English parliament in the first year of king William's reign: That every lord and gentleman, who was included in this capitulation, should be allowed to carry arms for defence or amusement: That the garrisons should march away with all the honours of war: And that those who might choose to leave Ireland, should be permitted to carry off their effects to any country except Britain, ships being provided for that purpose by the British government. Fourteen thousand Irish availed themselves of this article, and left their native country."

As William was now completely master of Ireland, it was hoped and expected that he would immediately summon an Irish parliament, but this he did not do till 1692, when he wanted money. In the mean time the English parliament legislated for Ireland; the most important of their acts was one to substitute other oaths, instead of the oath of supremacy, which, in fact, excluded Catholics from both houses of parliament. In 1692, when the Irish parliament met, it became evident that the commons were disposed to stand up for the rights of their country much more firmly than William wished or expected; they even went so far, as to contend that Poyning's law did not extend to money bills, and rejected one that was sent over to them from England, expressly because it had not originated with them. This parliament was therefore dissolved, in the hopes that the next would be less sturdy in the maintenance of their privileges.

In 1695, a new parliament was assembled, which, among other things, explained and confirmed the act of settlement, and confirmed the articles of Limerick, but not without such modifications and alterations as were by no means consonant to their spirit, and therefore were not justifiable: this parliament also passed some penal statutes against the Catholics. The great majority of its members were by no means disposed to question the authority of the English parliament; but some of the members of the commons stood resolutely up, not merely for the independence of the Irish upon the English parliament, but even for the independence of the kingdom of Ireland upon the kingdom of England.

The reign of queen Anne, so far as it regards Ireland, was distinguished principally by the severe penal statutes which were passed in the Irish parliament against the Catholics. It never seems to have occurred, that excessive severity only tended to increase the bigotry and ignorance against which it was directed, and that mild measures, aided by endeavours to enlighten the Catholics, and adopted in the spirit of charity, without a constant reference to the state of Ireland as a conquered country, would much more effectually have promoted the object which the British government, and, under their influence, the Irish parliament, professed to have in view. But, besides the irritation which was thus produced among the Irish Catholics, the Irish nation

in general were constantly reminded, in the most galling and unnecessary manner, of the dependence of their parliament upon that of England; and the violence of party—always great in Ireland—was augmented by the English government, to serve the paltry purposes of political intrigue.

In 1724, dean Swift distinguished himself by the Drapier's letters, the object of which was to point out the consequences that would result from a patent granted to a man of the name of Wood, for supplying Ireland with a copper coinage. Such was the ferment occasioned by these letters, that the patent was revoked next year. It is now pretty well ascertained that Swift was not the patriot he was then considered, and that Wood's coinage (though the granting him a monopoly was improper and unjust) would by no means have been the source of profit to himself, or so prejudicial to the people, as was represented in the Drapier's letters. But Ireland, at this period, was admirably adapted to be the scene of every kind of political imposture and intrigue. She was miserably governed; her interests were never consulted, but always sacrificed either to the interests of England, or, what was worse, and more provoking, to the interests of such individuals as the British ministry wished to oblige. The viceroy only came over once in two years. The effective power was with the lords justices, and their time and thoughts were occupied in forwarding the plans of the British cabinet, and promoting their own private interests.

The privileges of the Catholics, already greatly curtailed, were still further encroached upon, by an act passed in 1727, by which they were totally deprived of the elective franchise. Such, however, was their attachment to their native soil, that, though a scarcity, reaching almost to a famine, drove thousands of Protestants to America, scarcely any Catholics emigrated.

In 1745, when a rebellion raged in the heart of Britain, and when the British ministry, conscious of the harsh and unjust manner in which they had treated Ireland, were apprehensive that she also would encourage the Pretender, they sent over the celebrated earl of Chesterfield, who so well discharged his duty, that he discountenanced all party distinctions; gave to the Catholics the full protection of the laws; and, by similar conduct in other respects, prevented the Irish even from indulging a wish to support the Pretender; so that the unexpected and singular spectacle was exhibited, of Ireland tranquil and loyal, at a time when Scotland, and even England, teemed with favourers of the exiled family.

In 1749, the power of the Irish parliament was again brought under discussion, in consequence of the intended application of the surplus of the hereditary revenue of the crown towards the payment of the national debt. The question was, whether the right of disposing of this surplus was vested in the king or the Irish house of commons; or, in other words, whether his majesty's previous consent was necessary. At this time the English party gained their point; but when the question was renewed in 1753, the patriots were victorious.

In 1759, Britain and Ireland were alarmed with the preparations for invasion making in the French ports; but no landing took place, except that of Thurot with 600 men at Carrickfergus, and he re-embarked in the course of a few days. The conduct of the Irish troops, as well as of the peasantry, on this occasion, proved that they were much more loyal and worthy of confidence than they were allowed to be by those who calumniated them, for they were eager to rush to the defence of their country; and such as were engaged behaved with surprising valour and fidelity.

We now come to the time of the first appearance of those associations of the peasantry, and others of a higher class, for purposes of outrage, or of effecting political objects, by which the history of Ireland is henceforth so much distinguished. In 1762 the Whiteboys first created alarm. They took this name, which succeeded that of Levellers, from the circumstance of their covering their ordinary dress by a shirt or white frock. They consisted of labourers in the woollen manufacture, who had been driven out of employment by its decline; and of labourers in husbandry, who had been reduced to the same state, in consequence of the general conversion of arable into pasture land. To add to their distress, at this time a spirit of enterprise and improvement had recently promoted the enclosure of commons, on which these people had previously enjoyed the right of commonage. The outrages of the Whiteboys were dreadful; and the alarm was greater than even they warranted, in consequence of a suspicion that they were instigated by, and connected with, the Catholics. The next year an insurrection arose in Ulster. In this only Protestants were concerned. The cause of this was the hardships under which, it was alleged, the poorer classes laboured with regard to keeping the roads in repair. The insurgents called themselves *Boys of Oak*, from wearing oaken branches in their hats. They soon, however, carried their views beyond their original object; and, on their proceeding to interfere violently with respect to this, and the rent of land, they were put down by an armed force.

The first circumstance, after the accession of George III., connected with the history of Ireland, that deserves our notice and record, was the passing of the octennial bill, in 1768. The parliament of Ireland, unlike that of Britain, continued in existence as long as the monarch lived, being dissolved only by his death taking place. In 1761, an attempt was made by Lucas and others of the patriotic party, to limit the duration of the Irish parliament, and to place it on the same footing, in this respect, as the British parliament; this, however, did not succeed, and it is even doubtful whether the British government intended that the measure should be carried in 1768; for the British privy council returned the heads of a bill transmitted to them for limiting the duration of the Irish parliament to seven years, with an alteration which extended the duration to eight years; probably expecting that, by this interference, the Irish parliament would be induced to reject the bill altogether; but the Irish parliament, with great temper and good sense, passed the bill as returned to them.

At this period, lord Townshend was lord-lieutenant. His favourite and principal object was to destroy the power of the Irish aristocracy, and to take out of their hands the influence and distribution of places and pensions, which had been hitherto allowed them, in consequence of the supposed necessity of courting their favour and votes. This was a difficult point; but the viceroy carried it, though not by the most justifiable means. From this time, the lord-lieutenant, or in other words, the British government, was regarded and treated as the only source of honours or emoluments. During the administration of this nobleman, who was very popular among the Irish, not merely on account of his public measures, but also on account of his disposition and manners, open and convivial, and thus highly congenial to those of the people over whom he was placed, some disturbances broke out in Ulster, in consequence of a system introduced there of letting land on fines. As the great majority of the small farmers and peasantry were totally unable to pay these fines, and were consequently deprived of their farms, they became des-

perate, and committed such violent outrages on those who had taken their lands, that government was obliged to have recourse to military force. The insurrection was thus quelled; but the distressed inhabitants, deprived of the means of subsistence, were driven to America in great numbers.

The breaking out of the American war, produced a remarkable change in the language and conduct of the British government as they related to Ireland; proposals were made in the British house of commons in favour of Irish commerce; and some of the penal statutes against the Catholics were annulled. They were now enabled to acquire full property in land, and a son could no longer force a settlement from his father by conforming to protestantism, provided the Catholics subscribed an oath of allegiance and a declaration, which were prescribed. Still, however, Irish commerce and trade languished, and the patriots of Ireland aimed at much greater privileges with respect to it, and to their political state in general, than had yet been granted. The means by which their views might be forwarded were at hand. The American war had drawn from Ireland nearly all her regular forces, and her coasts, thus unprotected, were exposed to invasion. In consequence of the town of Belfast not receiving a garrison adequate to their protection, the inhabitants, in 1779, entered into armed associations to defend themselves against the enemy. This gave rise to the system of volunteers, which soon spread over the whole country. The Irish now began to feel their strength, and even the house of commons unanimously passed a resolution, on the first day of their session this year, that, in their address to the king, it should be represented to his majesty, that "it was not by temporary expedients, but by a free trade alone, that Ireland could now be saved from impending ruin;" and in order to give effect to this address, they voted their supplies only for six months. A motion was also made, that the granting of new taxes would at that time be inexpedient, which was carried by a large majority. Thanks were voted, unanimously, in the house of commons, and, with only the dissentient voice of the lord chancellor, in the house of lords, to the volunteers, for their exertions in defence of their country. Lord North, who was at this time prime minister, now found himself obliged to give way; but hoping that the Irish would be content with the removal of commercial restrictions, he carried a bill through the British parliament, which in some measure effected that object. But the Irish looked to greater objects; and, unfortunately for his own views, lord North, in order to induce the British manufacturers and merchants to agree to his commercial concessions, had represented them as a boon resumable at pleasure. The Irish thus learned, that what had been granted, had been granted, either through fear, or as a matter of favour, and not as their right, and they became sensible that they could not be secure, unless they had an independent legislature of their own. Resolutions to this effect were published by the different volunteer corps, who, in order that they might act with more effect, formed a union among themselves, and they were not only animated by the same spirit, but, in all their resolutions and proceedings, directed to the same object.

This spirit animated all ranks and classes: it was no longer an association confined to one part of the kingdom, composed of ignorant and poor men, without talents or influence, and aiming at some local and temporary object. At the head of the Dublin volunteers was the duke of Leinster; and, on the 9th of June, 1780, with him in the chair, they resolved, "That the king, lords, and commons, of Ireland, only, are competent to make laws binding

the subjects of this realm ; and that they would not obey or give operation to any laws, save only those enacted by the king, lords, and commons, of Ireland, whose rights and privileges, jointly and separately, they were determined to support with their lives and fortunes." The house of commons, which had hitherto gone along with the sense of the nation at large, seems now to have been placed under ministerial influence, or at least to have been of opinion that the nation were proceeding too rapidly and too far ; for a motion made by Mr Grattan, that no power on earth, save the king, lords, and commons, of Ireland, had a right to make laws for Ireland, was withdrawn ; and the Irish parliament, acting in the spirit which caused this motion to be withdrawn, passed into laws two bills which had been altered by the British cabinet. Hence the parliament became very unpopular.

In 1781, the force of the volunteers had been augmented to 50,000 men. By forming committees of correspondence and a national committee, they gave to their system a single animating spirit, by which their power was wonderfully increased ; and as the British government still obstinately refused to comply with their requests, a crisis seemed to be at hand. At this period, that administration which had lost Britain her American colonies, resigned ; and they were succeeded, in March, 1782, by a Whig administration, at the head of which was the marquis of Rockingham. The duke of Portland was immediately appointed lord-lieutenant. Mr Grattan moved an address to the king, in the house of commons, which was unanimously carried in both houses, in which it was declared, that " the crown of Ireland was an imperial crown, inseparably annexed to the crown of Great Britain ; but that the kingdom of Ireland was a distinct kingdom, with a parliament of her own, the sole legislature thereof ; that in this right they conceived the very essence of their liberty to exist ; that in behalf of all the people in Ireland, they claimed this as their birthright, and could not relinquish it but with their lives ; that they had a high veneration for the British character ; and that their determination was in sharing the freedom of England, to share also her fate, and to stand or fall with the British nation." The lord-lieutenant assured parliament that the British legislature had concurred in a resolution to remove the causes of their discontents, and that his majesty was graciously disposed to give his royal assent to acts calculated to fulfil their wishes. As an earnest of the sincerity of this declaration, a law was passed, by which all interference of the British privy council to alter Irish bills was abolished, and the parliament of Ireland thus placed on the same footing as that of Britain. Acts were also passed for the limitation of the law against mutiny to two years ; for the right of habeas corpus, and for the independence of the judges ; and the act by which the Irish house of peers had been deprived of their supreme judicial power in their own country, was repealed. These concessions, however, were not deemed sufficient by some patriots, particularly by Mr Flood, who brought in a bill, declaring the sole and exclusive right of the Irish parliament to make laws in all cases whatsoever, both internal and external, for the kingdom of Ireland : only six members voted for this motion. Mr Grattan opposed it ; and the volunteers of Leinster, Ulster, and Connaught, were likewise inimical to it.

The volunteers having accomplished the objects which they originally had in view, did not disband themselves, but directed their views and exertions to a reform in parliament. In order to act with vigour and effect, they followed their former plan of a national convention, which they appointed to be held

in Dublin on the 10th of November, 1783. On the 29th of the same month, a motion was made in the house of commons by Mr Flood, founded on the resolutions of this convention, which, after a long and warm debate, was rejected by a very large majority. This termination, instead of rousing the volunteers to perseverance, as it would have done, when they had their original object in view, seems to have disconcerted and alarmed them ; for the convention adjourned to an indefinite period, after having passed a resolution to carry on individually, their efforts for a parliamentary reform ; and having agreed to address the king, expressing their loyalty, and beseeching him not to ascribe their efforts to restore the constitution to its pure and pristine form, to any love of innovation, or want of attachment to his government or power. Soon after this the volunteer system declined, ministers hastening its decline by raising fencible regiments, into which they drew the officers of the volunteers by pecuniary inducements.

The cause of parliamentary reform, though no longer supported by the volunteers in their associate character, was not deserted by the people, or by its advocates in parliament ; and their hopes were raised by the circumstance, that Mr Pitt, who had been its most strenuous supporter, was now prime minister. It was soon found, however, that Mr Pitt was no longer of the same opinion ; and Mr Flood's motion for leave to bring in a bill to reform the Irish house of commons, was negatived, though not till after a long debate. The advocates for this measure, out of doors, were not cast down ; the citizens of Dublin, legally convened by the sheriffs, voted a series of resolutions in favour of this measure, and also appointed a committee to prepare an address to the people at large, and a petition to the king. The people were invited to form a national congress, composed of five persons from every county and large town ; and the meeting of this congress actually took place in Dublin, on the 25th of October, 1784, notwithstanding the endeavours of government to prevent it, which were carried, at least, as far as the law warranted.

The system of tithes has always been a source of ill will, even where those who paid them were of the established religion ; but it seemed very hard and unjust to the Catholics, that they should pay towards the support of a clergy whose services they did not need, nor wish for. Besides, the tithes pressed hard on the poor renters of a piece of ground, perhaps scarcely large enough to support a man and his family, even if he had received the whole produce. From this feeling with regard to the oppression of tithes, arose, in 1786, a species of insurrection in the south of Ireland, carried on by persons who styled themselves Right-boys. They administered oaths, binding the people not to pay more as the tithe of an acre, than a sum they fixed—to permit no proctor—and not to allow the clergyman to take his tithes in kind. Not being sufficiently opposed in this outrage, they proceeded farther ; to fix the rents of land—to raise the wages of labour—and to oppose the collection of the tax called hearth-money. This called forth the attention of the legislature, and in 1787 an act was passed, to prevent tumultuous assemblies and illegal combinations.

At the breaking out of the French revolution it was natural that those in Ireland, who had been so long and so ardently endeavouring to gain for their own country what they deemed its rights, and essential to its prosperity, should rejoice at the event when it began, and that they should feel, by it, inspired to renew their attempts to obtain their favourite objects of parliamentary reform and Catho-

the emancipation. The mode in which they might hope to attain these objects seemed pointed out to them: by the volunteers,—by union and associations they had prevailed, and thus also they might be equally successful. Accordingly, in June 1791, there appeared at Belfast the plan of an association, under the name of United Irishmen; and in November this association was actually instituted at Dublin: their declared object was, “the forwarding a brotherhood of affection, a communion of rights, and a union of power, among Irishmen of every religious persuasion, and thereby obtaining a complete reform in the legislature, founded on the principles of civil, political, and religious liberty.” Such were their avowed objects; but there is reason to believe, that, even at the first formation of this association, the leading members looked further; or, at least, that they had determined, if it should be necessary, to obtain their professed objects by means inconsistent with public tranquillity, and with their duty as subjects. That they had such a necessity in contemplation, is evident from the formation in Dublin of national guards, distinguished by a green uniform, and by buttons with a harp under a cap of liberty instead of a crown. The 9th of December 1792 was appointed for the general muster of these guards, and all the volunteer companies were invited to attend; but the muster never took place, in consequence of the strong measures of precaution adopted by government. Thus prevented from assembling, the leading men among the United Irishmen put forth a paper, signed by Archibald Hamilton Rowan as their secretary, in which they expressed their expectation that the volunteers would resume their arms for the maintenance of tranquillity against foreign and domestic enemies, and the Protestants generally to choose deputies to a national convention, with which, when formed, the Catholics might act. The Catholics, as might be supposed, were not indisposed to take advantage of this state of the country. Besides the grievances which were common to them and the Protestants, they had various grievances of their own, arising from their religion; and from the declaration of the United Irishmen, they were led to hope that the Protestants, so far from opposing their claims, would now co-operate with them in their endeavours to obtain them. Accordingly they also had their convention, which assembled on the 3d of December, 1792, in Dublin. After voting a petition to the king, and appointing a permanent committee for the management of Catholic affairs during the recess, they adjourned. That the real nature of the claims which they put forth might be understood, and the objections generally urged against their claims being complied with might be removed, they abjured the dangerous tenets which they were commonly supposed to entertain—that excommunicated princes might be murdered or deposed by their subjects; that the murder of heretics is lawful; that no faith is to be kept with them; that they could be absolved from their oaths of allegiance; that the pope had any jurisdiction within the realm; or that any human power could forgive sins, without sincere repentance. They also renounced all claims to the estates of their ancestors, which had been forfeited; and disavowed all designs of subverting the religious establishment of Ireland.

The government seemed to think, that the safest conduct for them to pursue was to avoid both extremes; they were not disposed to grant all the Catholics wished, nor to withhold every thing. In conformity with this determination, in 1793, the legislature admitted the Catholics to the practice of the law—to intermarry with Protestants—and to an unrestrained education. The legislature, during this session of parliament, also passed a law to prevent

the election, or other appointment, of conventions, or other unlawful assemblies, under pretence of preparing or presenting public petitions, or other addresses, to his majesty or parliament. This act was directly aimed at a proposed meeting of a national convention of the United Irishmen at Athlone, which was prevented. A report of a secret committee of the house of lords threw much light on the views and proceedings of the United Irishmen, as well as on those of a description of insurgents called Defenders. The latter were Catholics in Armagh, Louth, Meath, and the adjacent counties, who, having first associated to defend themselves against the ill treatment inflicted on them by gangs of Presbyterians, called Peep-of-day Boys, became afterwards the assailants.

We have mentioned that Archibald Hamilton Rowan was secretary to the United Irishmen at the time their manifesto was published; he was on that account arrested, and in 1794 brought to trial. It was suspected at the time of his trial, that the views of the United Irishmen went farther than they avowed, and that the utter subversion of the constitution, and the separation of Ireland from England, was in their contemplation, and the object of their meetings and schemes. This was afterwards proved on the trial of an English clergyman of the name of Jackson, for a treasonable correspondence with the agents of the French government; for Rowan, who had been condemned to a fine, and imprisonment for two years, contrived to escape out of prison, and fled out of the country, conscious that, on the trial of Jackson, evidence of his real designs would be brought to light. Jackson was condemned, but he took poison, and expired before he was removed from court. Two others, who were leading men among the violent democratic party, Napper Tandy and Theobald Wolfe Tone, the principal framer of the United Irishmen, also fled from their country. Indeed, there was now too much reason to believe, that the United Irishmen not only aimed at a separation from Britain, but aimed at this object by means of the co-operation of France,—a method at once most dangerous to that liberty which they professed themselves so anxious to secure, and utterly at variance with real patriotism or enlightened views.

It was not to be supposed that the French government was ignorant of the state of Ireland, or indisposed to take advantage of it in their war with Great Britain. Indeed it was matter of surprise that they had not attempted to land troops in a country so disturbed, and in which there was avowedly so numerous and active a part of the inhabitants desirous to throw off the British yoke, and for that purpose, to accept any foreign assistance that might present itself. An agreement was in fact made between the leading men in the Irish Union, and the French directory, for the landing of a French force in Ireland, on condition that the invading army should act as auxiliaries, receiving their pay and instruction from the Union. As soon as this arrangement was settled, preparations for the invasion of Ireland were made at Brest. The Irish Union, in order to be ready to second the efforts of their new allies, were uncommonly active and zealous in their preparations and plans; but, in the midst of these, they were thrown into a state of uncertainty, and induced to suspend their operations, in consequence of receiving, first, the intelligence that the invasion would take place immediately, that is, in the beginning of the winter of 1796; and almost immediately afterwards, a letter, which they had no reason not to regard as authentic, that the invasion would be deferred till the spring of 1797. The invading fleet, however, anchored in Bantry Bay, on the 24th of December, 1796; but as the general, and a great part of his troops were on board ships that had

not arrived, the admiral, after waiting for him a few days, returned to Brest, having previously ascertained, however, that the country was well defended, and that even the peasantry, towards whom the French had been taught to look for immediate and hearty co-operation, were apparently adverse to them.

A proclamation was issued on the 17th of May, 1797, declaring the civil power inadequate to quell the insurrection; and this proclamation was followed by orders for the military officers to act without waiting for any authority from the civil power. The military, who had previously been highly irritated by the resistance of the insurgents, and who, it is too probable, had entered Ireland, with the belief that it might be treated in all respects as a conquered country, now gave way, in too many instances, to the most oppressive outrages. Under the pretence that arms were concealed, houses were sometimes burnt or plundered; and the military torture of the picket was employed to force a discovery. The United Irish, perceiving that their only chance of success was by assuming the appearance of being reduced to obedience, and conducting their operations in a more secret manner, discontinued their meetings; and the state of the country generally improved so much, that in August, 1797, the administration of justice was again committed to the civil power. But the United Irish were only laying their schemes deeper, and were inactive and tranquil only, that they might burst out with more violence and effect. Hitherto they had been chiefly confined to the northern provinces; but now the associations began to extend to the western and southern parts of Ireland, and the whole organisation to assume a military form. According to their new plan, the lowest societies consisted of twelve persons, who lived near one another, and among whom there was frequent and confidential intercourse. Five of these societies elected each a secretary, and these secretaries formed a baronial committee, which had the superintendence of the first society. Ten of these lower baronial committees elected each a delegate, and the ten delegates composed an upper baronial committee, which directed the business of the ten lower committees. In like manner was the organization of county, district, and provincial committees effected. The supreme command was lodged in an executive directory, which was composed of five persons, unknown to all except the secretaries of the four provincial committees. From this directory the orders were conveyed in the most secret but efficient and prompt manner; and they were instantly and fully obeyed. Such was the civil organization of the Irish Union. The military resembled it, and, in fact, was grafted upon it. The secretary of each of the lowest societies was its non-commissioned officer; and the delegates of the lower and upper committees were respectively captains and colonels. There was also a military committee appointed by the directory, to contrive plans for the direction of the national force towards the grand object they had in view. In May, 1797, the number of men enrolled as members of the Irish Union in Ulster alone, was nearly 100,000. In the other parts of the kingdom, except Dublin and the counties of Wexford, Kildare, East Meath, West Meath, and King's County, their numbers were comparatively few; but they were using their utmost endeavours to extend the Union all over Ireland.

As soon as the members of the Irish Union found that they could not propagate their views by means of newspapers, they had recourse to hand-bills, which were privately printed and circulated by their agents. In these, abstinence from spirituous liquors was recommended, in order that the revenue might be impaired: and this recommendation, which it might have been

thought no motive would have induced the lower classes of the Irish to follow, was obeyed so generally and faithfully, that their habits were observed to be decidedly more sober than usual. The members were also cautioned against purchasing the quit-rents of the crown, as the bargains would not be valid in case of a revolution. A caution was also given against the acceptance of bank notes. All these circumstances evidently proved that the Irish Union were still in hopes of accomplishing their object by a revolution; but, as they could not hope for this by their own unaided efforts, they again had recourse to France. Assistance was readily promised them; and preparations for the invasion of Ireland were made at Brest and in the Texel; but the expedition from the latter place was rendered abortive, by the defeat of the Dutch fleet at the battle of Camperdown. Still the Irish Union looked towards assistance from the Brest expedition; but the French government appearing to have forgotten their promise, Arthur O'Connor, who was a member of the Irish directory, was commissioned to proceed to France; but, on his passage through England for that purpose, in February, 1798, he was arrested, along with an Irish priest of the name of Coigly, and Binns, a member of the corresponding society of London. They were tried; O'Connor and Binns were acquitted, but detained on another charge of treason; Coigly was condemned and executed. By this time, the number of men sworn into the conspiracy amounted nearly to half a million, and plans were formed for the simultaneous rising of this body. Their object, however, was discovered by a man of the name of Reynolds, who was a delegate for the province of Leinster; and from his information, the members who formed the committee of this province were arrested. Emmet, Marnevin, and Bond, members of the directory, were also arrested. Government, at the same time, by the seizure of papers, were made thoroughly acquainted with all the plans of the Union, and thus were enabled to frustrate them. The Union, thus deprived of their directory, proceeded to elect new members, among whom were two brothers of the name of Sheares; but neither these nor the other members were equal in talents to the former members; and yet greater talents were now requisite, not merely on account of the discoveries made by government, but also because the lower members of the Union, wearied with waiting, and anxious not so much to accomplish the political objects of the Union, as to gratify their own private revenge, could not be managed except by men of the greatest talents and influence.

On the 30th of March, 1798, government issued a proclamation, which proved that they meant to adopt the most vigorous measures which were in their power, for the immediate suppression of the disaffection and disorders in Ireland. At the same time general Abercrombie, who then commanded the forces in Ireland, was directed by the lord-lieutenant to proceed with his army into the disturbed counties, vested with full powers to act as he should think proper. His first object was to restore the discipline of the army, which was in such a state, that it could not be safely trusted with the execution of the orders he meant to issue. Afterwards, on the 3d of April, he published a manifesto, calling upon the inhabitants of Kildare, where his headquarters were fixed, to surrender their arms within ten days, and, in case of non-compliance, threatening that large bodies of troops should live among them at free quarters, promising rewards to those who would give information of concealed arms or ammunition, and denouncing other severities, in case the inhabitants did not return to a state of tranquillity. At the expiration of the ten days, the troops were quartered on those who were

known or suspected to be disaffected; and their behaviour was such as in most instances might be expected from men of their habits and feelings, hitherto little accustomed to strict discipline.

The insurgents did not seem intimidated by these proceedings against them; and as they were ignorant that government were acquainted with their plans, they still persevered in the determination to rise in a body on a fixed day. Before that day arrived, however, government caused lord Edward Fitzgerald, who had contrived the plan of attack, and who was distinguished for his boldness, talents, and influence, to be arrested. He made a desperate resistance, and died soon afterwards of a wound which he received before he was taken. The two brothers Sheares, and other conspirators, were arrested the same month; and, on the 21st of May, the plan of insurrection was announced by lord Castlereagh, secretary to the lord-lieutenant, to the lord mayor of Dublin. The night of the 23d was the time fixed for it. An attack on the troops stationed near Dublin, and on the artillery, was to have been first executed. The castle was, about the same time to have been surprised; after which, the parties engaged in these enterprises were to have united. The stoppage of all the mail coaches on the great roads, was to have been the signal for the rising of the people in the various parts of the country. The scheme was certainly well arranged, and had it not been discovered, might have been attended with the most disastrous consequences.

Even though thus discovered, the insurrection broke out in a manner that caused great alarm, and, for some time, exposed parts of Ireland to all the horrors of a civil war. On the 24th of May, the insurgents, though they were nearly without leaders, and with scarcely any arms except pikes, commenced their operations by an attack on Naas, Carlow, and other places, from which they were repulsed with loss. They had previously destroyed the mail-coaches in their road to Dublin, to give notice to their confederates that they were about to commence their operations, and to retard the communication of them to government. As soon as the first acts of rebellion took place, general Lake, who had succeeded general Abercrombie in the command of the forces, issued a proclamation, in which he expressed his determination to use, in the most summary and vigorous manner, the powers with which he had been entrusted to suppress the rebellion; and commanded all persons of every rank, except officers and magistrates, to remain in their houses from nine o'clock at night till five in the morning. Proclamations were also issued by the lord mayor of Dublin and the lord lieutenant. In the first, all persons in Dublin were ordered to give in a list of their arms, or to surrender them if they had not a license to possess them; and every housekeeper to fix on the outside of his door a list of the names of all persons resident in his house. In the second proclamation it was stated, that orders had been sent to all his majesty's general officers in Ireland, to punish, according to martial law, all persons assisting in the rebellion. The progress of the rebels towards the south-west was checked by their repulse at Carlow; but the city of Dublin was still partially blockaded by them. To complete the plan for its relief, Sir James Duff made a rapid march with 600 men from Limerick, and arriving at Kildare, opened the communication between the capital and the country.

On the 26th of May, the insurrection broke out in the county of Wexford, where it was not apprehended that the insurgents were in great force. They were headed by a priest of the name of Murphy, a ferocious and ignorant fanatic. On the 27th, two bodies of them made their appearance at Oulart and Kiltro-

mas. At the latter place they were defeated by 200 or 300 yeomen; but at the former place, where Murphy himself commanded, they were victorious. Murphy immediately proceeded to Enniscorthy, of which, by the assistance of the Catholic inhabitants, he gained possession. The inhabitants of the city of Wexford were now in great alarm, as they could plainly distinguish the flames of the burning houses at Enniscorthy. As they were little prepared for defence, they resolved to negotiate with the insurgents, or rather, to endeavour to persuade them to return peaceably to their homes. For this purpose, two gentlemen, who had been arrested on private information, were sent to them; but they kept one of these to be their leader, and sent the other back to Wexford. Against this place they now determined to proceed. Its small garrison took a position outside, but afterwards returned into the town, which was almost immediately evacuated, and taken possession of by the rebels. Their force was about 15,000 men; and by the capture of Wexford, the southern parts of the county, as well as the eastern and western, were at their mercy. They now divided into two bodies; one of which directed its march to Gorey, in the northern part of the county, in the hopes of thus forcing a passage to the capital; and the other to New Ross, by reducing which they would be enabled to enter the counties of Kilkenny and Waterford. The inhabitants of Gorey were apprised of their danger, but they trusted it would be averted by the arrival of troops under general Loftus and colonel Walpole, which immediately marched by different routes to attack the insurgents, who were posted on a hill seven miles from Gorey, under the command of a priest of the name of Roche. This man seems to have been possessed of great military talents, for he immediately resolved to quit his position with his whole force, upwards of 10,000 men, and attack Walpole while separated from Loftus's troops. He came up with him at Clough, and, attacking him quite unexpectedly, the British were defeated, with the loss of their artillery. Loftus, in the mean time, following the insurgents to Gorey, ignorant of the defeat of Walpole's corps, found them posted so strongly that he durst not attack them, but retreated into the county of Carlow. The body of the rebels who had marched towards Ross were not so fortunate. They had chosen for their leader a person of the name of Harvey, whom they had liberated from Wexford jail. He formed a plan of attacking three separate parts of the town of Ross at the same time: The attack was accordingly made in a furious but irregular manner. At first the rebels gained some advantages, but they soon were thrown into confusion; and general Johnson, who commanded a strong party of the regular army in the town, took advantage of this circumstance, and, after a desperate resistance from some divisions of the rebels, while others were totally without discipline or management, he succeeded in completely defeating them, and in saving the place. Enraged at this defeat, the rebels massacred in cold blood more than 100 of their Protestant prisoners at Wexford.

On the 9th of June, the insurgents advanced to the north to attack Arklow. The garrison in this place, not conceiving themselves strong enough to defend it against the rebels, left it, but afterwards returned, in consequence of their not attempting to seize it. The rebels, however, changed their plans, and advanced against it; but on the very day of attack, there arrived the Durham fencible regiment. The royal force now consisted of 1600 men, and, being arranged in lines, with artillery in front, they were enabled to cover three sides of the place, a

river protecting the other side. The force of the insurgents amounted to more than 20,000, but only about 4000 or 5000 of these had guns. They advanced with great impetuosity to the cannons' mouths, but they were in every assault driven back with immense slaughter. The battle lasted four hours; and though, during the whole of that time, the Durham fencibles bore the brunt of it, yet they stood firm and undaunted. The pikemen of the insurgents had not, however, yet come into action, and general Needham, apprehensive that the fencibles, wearied out with repeated attacks, would not be able to withstand these formidable assailants, sent directions to colonel Skerret, who commanded the fencibles, to retreat. This, however, he refused to do; and though it was now dark, and the insurgents might have profited by this circumstance, they discontinued the attack, and retreated.

The insurgents of whom we have been hitherto speaking, consisted almost exclusively of Catholics. They hoped to be assisted in their plans by the Protestants of the north of Ireland; but in this they were disappointed. There were, indeed, insurrections in Antrim and Down; but the Protestants who engaged in them, after a few skirmishes with the royal troops, gave up the enterprise, chiefly in consequence of being assured that the rest of the Protestants in the north, though in general well disposed, would not co-operate with them, having learned that the insurrection in Wexford was totally of a religious character, and that the Catholics engaged in it had repeatedly behaved with great cruelty to the Protestants. The insurgents in Wexford were thus left to themselves, and measures were taken by government to crush them effectually and speedily. On the 20th of June, their whole force was assembled on Vinegar-hill, near Enniscorthy. General Lake immediately formed his plan, which was, to surround this post; and for this purpose, all the divisions of the royal army were put in motion. In the mean time, the insurgents were guilty of the most atrocious acts of cruelty, not merely against those who had opposed their plans, but even against those who were known to be favourable to them, in case they were Protestants. These were dragged to Vinegar-hill, where, without trial, they were either shot or transfixed with pikes, or, in some cases, put to death in a still more barbarous manner. At Kilan, the Protestants of both sexes were collected, with an intention of burning them alive in their parish church, when fortunately their design was prevented by the arrival of a body of yeomen.

General Lake had collected nearly 13,000 troops, with a train of artillery proportionate to that number, for the attack on Vinegar-hill. This attack took place on the 21st of June. The town of Enniscorthy was the first object of attack, and the insurgents were driven from their post. They fled through a space of ground which was to have been occupied by the troops of general Needham. These had not come up, whether from missing the road, or some other accidental cause, or, as was supposed, because general Lake wished to leave the insurgents some outlet, is not ascertained. Wexford was taken by the royal troops the same day as Enniscorthy: previously, however, a battle had taken place at Horetown, between the troops of general Moore and the insurgents under Roche. The combat was long doubtful, but at length terminated in the defeat of the rebels. General Moore immediately encamped near Wexford, in order to secure the Protestants in that town from massacre. Before his arrival, however, the rebels in it had committed great outrages. These were principally directed and encouraged by a man of the name of Dixon. While the rebel force con-

tinued in Wexford, this man had not been able to carry his designs into execution; but soon after they marched out against general Moore, Dixon, at the head of a mob, which he had previously inflamed with whisky, murdered the Protestants in a manner, to which, for wanton cruelty, not even the atrocities of the French revolution can produce a parallel. In the mean time, the battle at Vinegar-hill, though strenuously contended by the insurgents, ended in their complete defeat. They were completely broken, and fled; and their loss in the battle and pursuit was so considerable, that the whole party was completely disheartened.

The movements and proceedings of the insurgents, after the battle of Vinegar-hill, were desultory, without union or plan. One body of them marched to Arklow, and, finding no royal troops there, massacred many of the inhabitants. Another body, under Murphy, who had originally raised the insurrection in Wexford, directed their march towards the country of Carlow, with the design of stirring up the inhabitants there and in Kilkenny; but in this they were disappointed, partly by the measures of the royal forces, and partly by the indisposition of the inhabitants. They now determined to return to Wexford, and on the 26th of June arrived at Kilkenny. Here they again changed their route, and moved towards the Wicklow mountains; but they soon found that they had no other chance of safety but by dispersing into small bodies, being no longer capable of withstanding the forces that were sent against them. After various movements and skirmishes, therefore, they finally dispersed.

Soon after these events, lord Camden, who had been viceroy during the rebellion, was recalled, and earl Cornwallis was appointed his successor. The appointment gave great and general satisfaction: the character of few noblemen, for political honour and humanity, was higher than that of lord Cornwallis, and his appointment seemed a pledge on the part of government, that they meant to pursue a different system in Ireland. He carried with him a general pardon for all who would submit, with very few exceptions; but his arrival could not immediately put a stop to the system which had been hitherto pursued. On the 3d of July, the pardon which lord Cornwallis brought with him was published in the Dublin gazette. His majesty's generals were thereby authorized to give protection to such insurgents as, being simply guilty of rebellion, should surrender their arms, abjure all unlawful engagements, and take the oath of allegiance. In order that this measure might receive the fullest authority and sanction, an act of amnesty was passed in favour of all who had been engaged in the rebellion, except the leaders, those who had been guilty of murder, and those who should not comply with the conditions above specified. From this amnesty were excluded Napper Tandy, and about thirty others who had fled to the continent. Afterwards the chief leaders of the rebellion were allowed to make their terms with government. Seventy-three of them bound themselves to give all the information in their power respecting the transactions of the United Irishmen, so far as it could be done without naming any individual; to emigrate into some country agreed upon, from which they were not to pass into any other country at war with Britain, or to return to Ireland.

The Irish insurgents had been long anxiously expecting assistance from France; at last, when it was too late, a force of about 900 regular troops, commanded by general Humbert, landed at Killybegs, on the 22d of August, and, being joined by some of the Catholic inhabitants, immediately marched to Castlebar. As soon as lord Cornwallis learned their

arrival, a force was collected, and marched against them. General Hutchinson arrived at Castlebar on the 25th, and was immediately joined by general Lake, the chief commander in the west. The British troops were drawn up in an advantageous position between Castlebar and the French, who were advancing towards it. At seven o'clock in the morning of the 27th, Humbert arrived with about 800 of his own troops, and 1000 Irish peasantry. His only artillery consisted of two small guns. The army opposed to him amounted to nearly 3000. Scarcely was the engagement begun, when the royal army were seized with a panic and fled, leaving their artillery, which consisted of six pieces of cannon, and their ammunition, behind them. Their officers in vain attempted to rally them: they fled, without stopping, thirty-eight miles, to Tuam, which they reached that night; and, at one o'clock of the 28th, some of them reached even Athlone, having marched eighty miles in twenty-seven hours. Here they were stopped by the arrival of the viceroy. From Castlebar, the French, after gaining this most unexpected victory, proceeded to the eastward, into the heart of the country, with what design it is impossible to conjecture, unless from the expectation of being reinforced by the peasantry on their march. General Lake and his column followed to watch their movements, while lord Cornwallis, with the chief army, moved towards Carrick, on the Shannon. At length, on September the 8th, general Lake having come up with their rear, at a place called Balamuck, a sharp action took place, which fortunately terminated in the surrender of the French, and the capture or dispersion of the rebels. The troops of Humbert amounted to 748 privates and 96 officers. The Catholic peasantry of the county of Mayo, who had first risen to assist the French, still continued in arms, notwithstanding the surrender of Humbert. They even attacked Castlebar, but were repulsed. They were afterwards obliged to take refuge in Killala, from which, being stormed by the royal forces, they were driven with great slaughter.

The French government at last seemed as if they meant to send assistance to Humbert; and, as a prelude to this assistance, a brig arrived near the north-west coast of Donegal, where it landed its new supplies. Among these was Napper Tandy, who had been constituted general of brigade in the French service. As soon, however, as he learned the fate of the army of Humbert, he reembarked. He was afterwards arrested at Hamburg by the British government, tried in Ireland, pleaded guilty, but was pardoned. Another attempt of the French to revive a cause now desperate was equally unsuccessful. A squadron, consisting of one ship of the line, and eight frigates, with troops and ammunition on board, despatched for Ireland, was fallen in with off the western coast of that island by the squadron of Sir John Borlase Warren, on the 12th of October, who captured the ship of the line and three frigates. Afterwards the rest, except two frigates, were taken. Another squadron, of three frigates, with 2000 troops on board, anchored in the bay of Killala on the 27th of the same month; but, on the appearance of some British ships, they set sail, and escaped.

The plan of a union between Great Britain and Ireland, appears to have been first proposed by the Irish peers, in their address to queen Anne in the years 1703 and 1707, but at this time the British cabinet was averse to it. Afterwards, when the Irish volunteers forced the British government to render the Irish parliament independent of that of Britain, a union was sought for by the British, but it was no longer an object of desire among any classes of the Irish. The almost uninterrupted

insurrections by which Ireland was disturbed after the commencement of the French revolution, seem to have suggested to the British cabinet the idea of seriously bringing about a union. On the 22d of January, 1799, the measure was recommended by the viceroy to parliament. In the house of lords a favourable address was voted by a large majority. In the commons, after a debate which lasted twenty-two hours, there was a majority of only one in favour of the measure. When it was again brought forward the next day, those who opposed the union had a majority of five. Before the conclusion of the session, however, those who were favourable to it had attained a majority; but the detail of the measure was postponed till the next year. In the British parliament, the question had also been introduced during the session of 1799, and, after considerable discussion, but with less opposition than in the Irish parliament, a series of resolutions, recommending a union, had been voted. When the Irish parliament assembled again on the 15th of January, 1800, a motion was made hostile to the measure, which, after a long and animated debate, was negatived by a majority of forty-two. On the 5th of February, lord Castlereagh communicated a message from the lord-lieutenant, in favour of a union, and developed the plan on which it was to be effected. On a division of the house for taking this message into consideration, there appeared 158 in favour of it, and 115 against it. The house of peers were more decidedly in favour of a union. In order to counteract the effects of opposition, government had recourse to those means, which the distribution of places of honour or emolument must always put in their power, and which too frequently have overcome the consciences of those who have been the most loud in their professions of purity, independence, and patriotism. By the active and judicious employment of these means, the majority in the house of commons had been greatly reduced, and the prospect of carrying the measure was rendered every day more favourable. Besides, many of those, both in and out of parliament, who, during the first impulse of their feelings, had reprobated the union, without considering the arguments that might be urged in favour of it, having become cool, and divested themselves of prejudice, resolved to support it.

The subject of the union being again introduced into the British parliament, it was discussed in both houses, and on the 2d of July received the royal assent. The articles of union were partly commercial and partly political. The proportion of revenue to be raised in the two kingdoms was fixed by a comparison of their aggregate imports and exports, by which Ireland was to raise two parts of the revenue for every fifteen raised by Great Britain, during the first twenty years after the union. At the close of that period, the proportion was to be regulated by parliament. One hundred commoners from Ireland were to sit in the imperial parliament, and the proprietors of disfranchised boroughs were to receive a pecuniary compensation. Four lords spiritual, by rotation of sessions, and twenty-eight lords temporal, elected for life by the peers of Ireland, were to sit in the house of lords. The first of January, 1801, was fixed as the commencement of the union.

After the union, the history of Ireland naturally falls into that of Britain. The reader is therefore referred to that article. The union, notwithstanding the many commercial advantages it bestowed on Ireland, did not bring that tranquillity to the country, which its advocates anticipated. The annals of the country are still unhappily marked by instances of insurrection and outrage, proceeding either from national jealousy, religious animosity, the feuds of clans

or families, or from the severe privations to which the peasantry are subjected by the exactions of middlemen and landlords.

Since the union, the most important event for Ireland has been the passing of the Catholic Emancipation bill in 1829, by which the political disabilities under which the Catholics had hitherto laboured were finally removed. In the article *Catholic Emancipation*, the reader will find an account of this bill, with an abstract of the various motions made respecting it, before it was ultimately carried. It is unnecessary, therefore, to enter upon the subject in this place.

**Topography.**—The greatest length of Ireland, measuring from N. E. to S. W., is 306 miles; its greatest breadth 174 miles. The total superficies of the island is, in square miles, according to Wakefield and Arrowsmith, 32,201. A late parliamentary document states it at 19,441,944 statute acres.

Ireland is divided into four large provinces, namely, Ulster, in the north; Munster, in the south; Leinster, in the east; and Connaught, in the west. These are subdivided into thirty-two counties; of which Ulster has nine, viz., Donegal, Londonderry, Antrim, Tyrone, Fermanagh, Monaghan, Armagh, Down, and Cavan;—Munster, six, viz., Waterford, Tipperary, Cork, Kerry, Limerick, and Clare;—Leinster, twelve, viz., Louth, Meath, West Meath, Longford, Dublin, Kildare, King's County, Queen's County, Wicklow, Carlow, Kilkenny, and Wexford;—and Connaught, five, viz., Galway, Mayo, Sligo, Leitrim, and Roscommon. The islands, of all sizes, belonging to Ireland are 196 in number, of which 140 are inhabited, containing a total population of 43,000. Of these islands, eighty belong to Connaught, seventy to Munster, forty to Ulster, and six to Leinster.

The following table exhibits the names of the counties of each province alphabetically arranged, the length, breadth, territorial extent, baronies, parishes, and chief towns of each county, with the distance of each town from Dublin.

PROVINCE OF ULSTER.

Ireland is distinguished for the number and extent of its lakes or loughs, its rivers, and its bays. Lough Erne occupies about one-sixth of the county of Fermanagh, measures forty miles in length, but varies in breadth from one mile to nine, and is adorned with about 100 islands. Lough Neagh washes the shores of five different counties, and is of a quadrangular form, 32 miles long by 16 in width. It is now navigated by steam-boats. These are the largest fresh-water loughs in Ireland. Donegal contains many small lakes, contributing to its picturesque scenery; one of them, called Lough Dearg, is celebrated as the theatre where superstitious ceremonies are annually enacted at St Patrick's Purgatory. There are upwards of twenty lakes in the county of Cavan, in one of which the river Erne takes its rise, the source of the great lake of that name. Loughs Melville, Nilly, and Gill, are the most interesting in the north-west angle; and in Connaught, the lakes called Carra, Mask, and Corrib, may be termed inland seas. There are four expansions of the Shannon, lakes Allen, Boin, Rea, and Derg. There are about thirty pools formed in the mountain glens of the county Clare; and Kerry is celebrated for its beautiful lakes at Killarney. The celebrated lakes of Glendalough and the beautiful lough of Luggelaw are numbered in the ten pools of the county of Wicklow; and the county of Westmeath is a region of waters. Here are Lough Ouel, the reservoir of the Royal Canal; Belhaven Lake, and the loughs called Ennell and Sillin, all possessing extensive areas; besides the largest and most beautiful, Derryvarragh. There are, besides, several great inlets or arms of the sea, which it is customary in Ireland to call loughs; the principal are Lough Swilly, Foyle, Larne, Belfast, and Strangford. The lakes of Ireland are so important as mediums of conveyance, that the rivers appear rather less valuable here than in other countries.

Many of the rivers of Ireland are extended through lengthened lines, and navigable for considerable distances. The Shannon is the noblest river in the island; indeed, it is without a rival in the three kingdoms, for size and extent of course. It rises at the foot of Culca mountain, in the county of Cavan, and passing by Carrick, Lanesborough, Athlone, Banagher, Portumna, Killaloe, and Limerick, falls into the sea, after a course of 190 miles, during almost the whole of which it is navigable. Besides a number of minor streams, the Shannon receives the Fergus below Clare and Ennis, the Suir below Ballinacree, and the Brosna near Banagher. The Liffey joins it at Lough Ree, and the Camlin near to Tarmonbarry. It is crossed by bridges at Carrick, Athlone, Banagher, Portumna, Killaloe, and Limerick. That at Portumna is of great length, and built of wood, the others are all of stone. The Suir is the second river in magnitude. It rises in the mountains of Kilkenny, and flowing past the large towns of Cahir, Chancel, and Carrick, washes the quays of Waterford, and falls into the Atlantic below Dunmore East, after having its waters swelled by those of the Nore and the navigable Barrow. The rapidity and floods of the Nore render improvement in its navigation impracticable; but the Barrow, which rises in the King's County, and takes a southerly course of many miles, affords a valuable line of inland navigation. The Lee rises in the romantic lake of Gougane Barra, in the county of Cork, and after a short course from west to east, and being augmented by numerous rivulets, falls into the harbour of Cove, six miles below Cork city, the head of its navigation. There are three Blackwater rivers in Ireland. The southern is the finest river. It rises in the borders of Kerry and Cork, and flows by Mill Street, Mallow, Fermoy, Lismore, Capouquin, and Youghal, at the last of which

places it is crossed by a wooden bridge of 1400 feet in length. The Slaney may also be ranked amongst the rivers of note in the southern counties; it takes its rise in the county of Wicklow, and passing down into Carlow and Wexford counties, becomes navigable at Ennisclorthy, and ultimately falls into Wexford Haven. The city of Dublin occupies both banks of the river Liffey, a stream which otherwise would be little known to geographers. The river flows out of a little pool in the county of Wicklow, called Liffey Head, and meandering into Kildare, turns eastward into Dublin, and running through the middle of the city nearly, falls into Dublin Bay. Few navigable rivers fall into the sea on the eastern coast, although there are many eminently suitable to the erection of mills and application of water power to machinery. The Boyne is navigable naturally as far as Drogheda, one mile from the coast; and a still-water navigation is formed by means of its waters to Navan, where the central Blackwater unites with the Boyne. Art has rendered the rivulet, called the Newry Water, both known and valued; and the Lagan, like the Liffey, derives its consequence from its proximity to Belfast, which stands on its northern bank. The Bann is the first river of note from Belfast to Coleraine. It is divided into two parts, the Upper rising in the Mourne Mountains, and discharging its waters into Lough Neagh, the Lower conveying the surplusage of that great lake into the Atlantic Ocean, a little to the north-west of Coleraine. Lough Foyle is the estuary of the river bearing that name, upon which the city of Derry stands, and as far as which it is navigable by vessels of 500 tons burden. Lighters proceed to Lifford, a distance of twenty-five miles; and an artificial communication renders Strabane accessible by water. The Morne and the Finn are tributaries to the Foyle. The Guibarra is the principal on the Donegal coast, except the outlet of Lough Erne, called the Erne River, known by its famous salmon-fishery. The Moy, which runs by Thalliner and Ardnaree, is navigable for a short distance, and also possesses a valuable salmon-fishery. The coast of Connaught is deficient in deep and navigable rivers, but this loss is amply supplied by an uncommon number of the finest natural harbours in Europe.

Ireland cannot, on the whole, be called a mountainous country, its central districts composing one vast plain, which crosses the country from east to west. It is, however, diversified by ranges of mountains superior in extent to any in England, with the exception of those in Wales. In the province of Ulster, the adjacent counties of Donegal, Londonderry, and Antrim are mountainous. Knocklade in Antrim attains an altitude of 1820 feet. The eastern half of the county of Down abounds also with lofty hills, projecting into the sea, and forming sublime and prominent features in the view. They are usually denominated the mountains of Mourne; and the summit of Slieve Donard, the loftiest, is elevated 2809 feet above the level of the sea. Tyrone and Monaghan are, properly speaking, hilly; but Sligo, Mayo, all the west of Connaught province, and particularly the county of Clare, present a continued and unbroken chain of mountain masses, interspersed with fertile valleys and spacious lakes. Benbulbin, in Sligo, reaches a height of 1697 feet. Culkagh, in Cavan, stands 2155 feet high, and Nephin, in Mayo, one of the most remarkable in Connaught, is 2600 feet over the surface of the sea. The most famous of the Connaught range, however, is Croagh Patrick, a cone-formed and conspicuous mountain, overhanging Clew Bay, and rising to an elevation of 2510 feet. An altar or cairn appears on its summit, to which pilgrimages are sometimes made, and on the west

side is discovered the beautiful marble called serpentine. This is the hill so famed in song and story, from which St Patrick is said to have banished all noxious animals existing in the island, and to have "bothered them entirely." The twelve Pins of Connemara are also remarkable landmarks, and enter into the composition of many interesting landscapes. South of the Shannon, the hills of Kerry raise their heads, and continue ascending towards the south, until the lordly Reeks of M'Gillicuddy are seen exalted to their proud pre-eminence; Carran-Tual, the highest, attaining an elevation of 3410 feet. Around stand Mangerton, 2550; Purple Mountain, 2280; and many others of nearly equal heights. The summit of Carran-Tual is the highest point in the kingdom. The chain extends away southward to the wilds of Glengarriff and Bantry, thence easterly to the Bogra hills, and along the south bank of the Blackwater. A little north-east of the Bogra hills are the Galtees, a chain of twenty miles in length, extending from Seefin, near Charleville, to the river Suir. The highest point of this range is elevated 2500 feet. In the King and Queen's counties is the fine range of the Slieve Bloom Mountains, the fruitful source of rivers and rivulets, and admitting of an easy passage from one side to the other in one place only, that is through the Gap of Glandine. Wicklow, in the vicinity of Dublin, is a mountainous region. Some of the hills are lofty, (Lugnaquilla is 3070 feet high,) and many are picturesquely formed.

*Agriculture.* Of the early agriculture of Ireland, very little is known. With a soil singularly prolific in pasture, and rather humid for the easy management of grain, it is probable that sheep and cattle would be the chief rural products for many centuries. In the twelfth century and earlier, various religious establishments were founded, and then it is most probable tillage on something like the Roman mode of culture would be introduced. The monks, says O'Connor, fixed their habitations in deserts, which they cultivated with their own hands, and rendered them the most delightful spots in the kingdom.

There is no evidence of any agricultural improvements having been introduced before the time of Elizabeth, when the enormous demesnes of the earl Desmond were forfeited, and divided amongst a number of English undertakers, as they were called, who entered into a stipulation to plant a certain number of English families on their estates, in proportion to the number of acres. Among others who received portions were, Sir Walter Raleigh, and Spenser, the poet. The former is said to have then introduced the potato.

The reign of James I. was one of comparative tranquillity for Ireland: the power of the judges, and of the English government, was extensively fixed; the Irish laws and customs were abolished, and the English laws were established in all cases without exception, through the whole island. Numerous colonies were also sent from England and Scotland, especially the latter, to occupy the forfeited estates; and seven northern counties were wholly allotted to undertakers. This was called the "plantation of Ulster," and was attended by the introduction of an improved agriculture, and by the linen manufacture, which is still carried on by the descendants of the first colonists in the same counties. The city of London participated in this distribution of land. The corporation having accepted of large grants in the county of Derry, they engaged to expend £20,000 on the plantation; to build the cities of Derry and Coleraine, and at the same time stipulated for such privileges as might make their settlement convenient and respectable. Under a pretence of protecting this infant settlement, or perhaps with a

view of raising money, the king instituted the order of Irish baronets, or knights of Ulster; from each of whom, as was done in Scotland with respect to the knights of Nova Scotia, he exacted a certain sum, as the price of the dignity conferred.

Of the husbandry of Londonderry a curious account was published about a century ago, by the archbishop of Dublin. He states that there was little wheat grown, and that of very inferior quality; the soil being considered as unsuitable to its production. Potatoes remained three or four years in the ground, reproducing a crop, which at the best was a very deficient one. Lime was procured by burning sea shells. The application of them in an unburnt state arose from accident. A poor curate, destitute of the means for burning the sea shells which he had collected, more with a view to remove an evidence of his poverty, than in any hope of benefit, spread them on his ground. The success which attended the experiment occasioned surprise, and insured a rapid and general adoption of the practice. The improvements made since the period of which the archbishop treats, Curwen remarks, are undoubtedly very considerable; and, whilst we smile at the very subordinate state of agriculture at that time, may we not on reasonable ground expect that equal progress will at least be made in this century as in the last?

A considerable impulse was given to the agriculture of Ireland after the rebellion of 1641, which was quelled by Cromwell, as commander of the parliamentary army in 1652. Most of the officers of this army were yeomen, or the sons of English country gentlemen; and they took pleasure in instructing the natives in the agricultural practices to which they were accustomed at home. Afterwards, when Cromwell assumed the protectorship, he made numerous grants to his soldiers, many of whom settled in Ireland; and their descendants have become men of consideration in the country. Happily these grants were confirmed at the restoration. Some account of the state of culture in that country at this time, and of the improvements which it was deemed desirable to introduce, will be found in Hartlib's *Legacy*.

The establishment of the Dublin Society in 1749, gave the next stimulus to agriculture and general industry in Ireland. The origin of the Dublin society may be dated from 1731, when a number of gentlemen, at the head of whom was Prior of Rathdowney, Queen's county, associated themselves together for the purpose of improving the agriculture and husbandry of their country. In 1749, Prior, through the interest of the then lord lieutenant, procured a grant of £10,000 per annum, for the better promotion of its views.

Arthur Young's Tour in Ireland was published in 1780, and probably did more good than even the Dublin Society. In this work he pointed out the folly of the bounty on the inland carriage of corn. His recommendation on this subject was adopted; and, according to Wakefield, "from that hour may be dated the commencement of extended tillage in Ireland."

The soil of Ireland is, generally speaking, a fertile loam, with a rocky substratum; although there are many exceptions to this description, and many varieties. Generally speaking, it is rather shallow; to which cause the frequent appearance of rocks near the surface, or at no considerable depth, is to be attributed. It possesses a much greater proportion of fertile land, in proportion to its extent, than either England or Scotland. Not only is the island blessed with this extent of cultivable ground, but it is almost all of such a quality as to yield luxuriant crops, with little or no cultivation. Sand does not exist except on the sea shore. Tenacious clay is unknown, at

least near the surface. Great part of the land of Ireland throws up a luxuriant herbage, without any depth of soil, or any skill on the part of the husbandman. The county of Meath, in particular, is distinguished by the richness and fertility of its soil. and, in Limerick and Tipperary, there is a dark, friable, sandy loam, which, if preserved in a chaste state, will yield crops of corn several years in succession. It is equally well adapted for grazing as for arable crops, and seldom experiences either a winter too wet, or a summer too dry. The vales in many of the bleakest parts of the kingdom, as Donegal and Tyrone, are remarkable for their richness of soil and luxuriance of vegetation, which may be often accounted for by the deposition of the calcareous soil, washed down by the rains of winter, which spreads the richest manure over the soil below, without subjecting the farmer to any labour.

The bogs, or peat mosses, of Ireland, form a remarkable feature of the country, and have been proved by the parliamentary commissioners to be of great extent. They estimate the whole bogs of the kingdom at 2,330,000 acres, English. These bogs, for the most part, lie together. In form, they resemble a great broad belt, drawn across the centre of Ireland, with its narrowest end nearest to the capital, and gradually extending in breadth as it approaches the western ocean. The bog of Allan is not one contiguous morass, but this name is indiscriminately applied to a great number of bogs, detached from each other, and often divided by ridges of dry country. These bogs are not, in general, level, but most commonly of an uneven surface, swelling into hills, and divided by valleys, which afford the greatest facility to their being drained and improved. In many places, particularly in the district of Allan, the rivulets which these inequalities of surface produce have worn their channels through the substance of the bog, down to the clay or limestone gravel beneath; dividing the bog into distinct masses, and presenting, in themselves, the most proper situations for the main drains, for which purpose, with the assistance of art, they may be rendered effectual.

Farming in Ireland is, generally speaking, in a backward state. With a few exceptions, such as the county of Meath, and some other well cultivated districts, the farmers are destitute of capital, and labour small crofts, which they hold of middlemen interposed between them and the landlord. The fact that in Ireland the landlord never lays out any thing upon repairs or buildings, coupled with the general inability of the farmer to do either in a substantial manner, is very significant as to the state of agriculture. But the worst features of the rural economy of this island are the entire want of capital in the farmers, and the complete indifference of the landlord to the character, wealth, or industry of his tenant. "Capital," says Wakefield, "is considered of so little importance in Ireland, that advertisements constantly appear in the newspapers, in which it is stated, that the preference will certainly be given to the highest bidder. Bargains are constantly made with a beggar, as a new tenant, who, offering next rent, invariably turns out the old one, however industrious." The rent of land in Ireland, from these causes, coupled with the excessive competition of the peasantry for small farms, as their only means of subsistence, has risen to a great height.

The agricultural implements and operations used in Ireland are of a rude construction. The plough, the spade, the flail, the car, all equally partake of imperfections and defects. The fallows are never attended to; three ploughings are usually deemed sufficient, and, from the imperfection of the plough,

the ground at the end is generally full of weeds. Trenching land is very general; they form it into beds, and shovel out a deep trench between them, throwing up the earth. Wheat is not by any means generally cultivated. The Irish wheat is, for the most part, coarse and of inferior quality, and does not yield so much saccharine matter by twenty per cent, as the English. Barley is more generally cultivated in Ireland than wheat, and is generally sown after potatoes. Oats, however, constitute the species of grain which is most extensively raised; it is calculated that, throughout the whole kingdom, there are ten acres of oats sown for one of any other species of corn. The Irish oats, however, are decidedly inferior to the English. The potatoes of Ireland have long been celebrated, both on account of their quantity and excellent qualities; they are cultivated on every species of soil, either in drills or lay beds.

The dairy is the most extensive and the best managed part of Irish husbandry. Kerry, Cork, Waterford, Carlow, Meath, Westmeath, Longford, and Fermanagh, as well as the mountains of Leitrim and Sligo, are principally occupied by dairy farms. Butter is the chief produce. The average number of cows on a dairy farm amounts to thirty or forty; three acres of land, of middling quality, are deemed necessary for the subsistence of each cow. A cow produces on an average eight quarts in twenty-four hours in summer, and five in winter; four good milkers will yield a quarter of a cwt. of butter in a week. The best butter is made in Carlow; the worst in Limerick and Meath. Generally speaking, the Irish are very cleanly in making this article; and it is exported to England, the East and West Indies, and Portugal. The art of salting butter, Chaplun observes, is better known in Ireland than in any other country. The grazing of Ireland is not, as in England, a part of the regular rotation of crops, but is carried on in a country exclusively devoted to the breeding of cattle, like the highlands of Scotland. Great tracts of the country also are devoted to the grazing of sheep. Roscommon, Galway, Clare, Limerick, and Tipperary are the chief breeding counties for sheep; and Galway, Clare, Roscommon, Tipperary, and Meath are the places where they are fattened. The sheep are of the long-wooled kind, and very large: they are never kept in sheep-folds, and hardly ever fed on turnips; which is chiefly owing to the very limited demand for mutton among the labouring people.

Ireland is divided, by Wakefield, into nine agricultural districts, in each of which the mode of culture is somewhat different from what it is in the others.

The first district comprehends the flat parts of Antrim, the eastern side of Tyrone, Down, Armagh, Monaghan, and Cavan. Throughout this district, the farms are extremely small, and the land is generally dug with a spade. Potatoes, flax, and oats are the crops usually cultivated, and these are grown till the land is exhausted, and suffered to "lie at rest," as they term it, till its strength is recruited by the cow, the goat, two or three sheep, and the poultry lying upon it for some years. The ploughs used in this district are of the rudest structure, and perform their work in the most slovenly manner. Three or four neighbours unite their strength to each plough, every one bringing his horse, his bullock, or his cow. All the other operations of agriculture are performed in an equally slovenly manner. The little wheat that is raised is "lashed," as they call it; that is, the grain is knocked out by striking the sheaf across a beam placed above a cloth: it is, however, afterwards threshed with a flail. The operation of threshing usually takes place in the highway, and it is

dressed by letting it fall from a kind of sieve, which, during a pretty strong wind, is held breast-high by a woman. Many cotters in this district have a cabin with no land attached to it. They hire an acre or two, for grass or potato land, from some cotter in their vicinity. The custom of hiring labourers is unknown. The neighbours all assist each other in their more considerable occupations, such as sowing and reaping. The dwellings here are miserably small; often too small to contain the numerous families that issue from their doors. Land is every where divided into the most minute portions.

Under the second district may be comprised the northern part of Antrim, Londonderry, the north and west of Tyrone, and the whole of Donegal. Agriculture here is in a worse state than in the preceding district. There is no clover, and hardly any wheat.

The third district comprehends the northern parts of Fermanagh. Here the farms are much larger than in the former, and the agricultural system pursued far superior. They plant potatoes on a lea, twice reversing the lands; and flax, oats, and weeds constitute the course. Some wheat is grown, but oats still form the prevalent crop. In the neighbourhood of Enniskillen, the farmers are so rich as to be able to eat butcher's meat daily, and drink smuggled wine.

The fourth district comprehends Sligo, Mayo, Galway, Clare, and parts of Roscommon and Longford. In some parts of this district the spade culture is pursued; but, in general, the land is cultivated by a plough drawn by four horses abreast. In Roscommon, the old custom of yoking the horses by the tail is still continued; although, as early as 1634, an act of parliament was passed against this absurd practice. Oats are chiefly raised in this district, and, along the coast, barley is cultivated. A large portion of the rent depends on the illegal distilleries, and much of the district is let on lease to several persons jointly, according to the village system.

In the fifth district, which comprehends Limerick, Kerry, the south side and northern part of Cork, and the county of Waterford, cultivation is in a very rude state; little corn is grown here, with the exception of the southern part of Cork. Land is extremely divided, and the farms very small. The greater part is a grazing country.

The sixth district includes the southern parts of Cork. The spade culture is here almost universal, and the farms unusually small. Hogs constitute the main support of the poor.

The seventh district includes part of Tipperary, with Queen's county and King's county. The best farming in Ireland is observable in this district; a systematic course of husbandry being pursued, by which the land is kept in good heart. Oxen and horses are used in the plough, and hedgerows and good wheat fallows are to be seen. Near Roscrea the cultivation of turnips is followed, and they succeed well. Ninety acres are considered a large farm. Leases are generally for three lives.

The eighth district comprises Wexford and a part of Wicklow. Beans are here sometimes introduced into cultivation, but they are sown broadcast, and never hoed. The mode of ploughing is very awkward: one man holds the plough, another leads the horse, and a third sits on it to keep it down.

The ninth district comprehends the northern part of Kilkenny, Kildare, the cultivated parts of Westmeath, Meath, and Louth. Wheat here enters into the system of culture, but the preparatory fallows are very bad. Clover has been introduced into the district, but under the bad system of sowing it upon land exhausted, and covered by weeds. Farms are large, and the mode of culture similar to the English.

STATEMENT of the SUPERFICIAL CONTENTS, and whether CULTIVATED or otherwise, of each COUNTY in IRELAND, together with the Estimated Annual Value thereof, the Amount of County Presentments, and the Population as enumerated in 1831.

**Manufactures.**—The manufactures of Ireland are not so extensive as the resources of the country might justify. The most important is the linen manufacture, but in point of antiquity the woollen takes precedence. It existed in Ireland at a very early period, and was the object of legislative enactment so far back as the 31 year of Edward IV. (A.D. 1462.) The jealousy of the English manufacturers, however, checked and depressed its increase by a variety of prohibitory acts, which they got passed through parliament at different periods, and which were only repealed at the Union. The manufacture is confined to the production of the coarser description of goods; as yet, no fabric of superfine cloth has been successfully made. Flannels are made in Wicklow, blankets in Kilkenny, and broad cloths at Middleton and Cork. The spinning of wool into yarn is much followed by the women in the north-west parts of the island. There are at present employed in establishments for the manufacture of woollen cloths upwards of 6,500 persons; worsted stuffs, near 3000, and flannels about 3000, making a total of 12,500 individuals.

The foundation of the linen manufacture in Ireland was laid by the unfortunate earl of Strafford, in the reign of Charles I., and during the time he resided in that country as chief governor. He sent to Holland for flax-seed, and to the Netherlands and France for competent workmen. The flax was sown, and succeeded according to expectation; spinners and looms were set to work; and his lordship, to animate others, embarked himself in the business, and expended in promoting it, £30,000, of his private fortune. Afterwards, the duke of Ormond supported very much the linen manufacture of Ireland, but it had not gained much ground at the time of the revolution, the woollen being the true and natural staple of the Irish, their climate and extensive sheep-grounds ensuring to them a steady and cheap supply of the raw material, much beyond the home consumption: and it appears from the preamble to the English statute of 10th and 11th William III., chap. 10, that they were at the time possessed of a profitable export of it. This export was supposed to interfere, and very probably did, with the export from Great Britain; and a plan was in consequence undertaken there, to annihilate the woollen trade of Ireland, and to confine the Irish linen manufacture in its place. Accordingly, an act was passed in England, 1698, for inviting foreigners to settle in Ireland, as the preamble recites, and with that view, enacting, that the import of all sorts of hemp and flax, and all the productions thereof, should from thence be admitted duty free from Ireland into England; giving a preference, by that exemption from duty, to the linen manufacture of Ireland, over the foreign, estimated at the time, as a report of the Irish house of commons, on the 11th of February, 1774, states, to be equal to 25 per cent.

The board of the trustees of the linen manufacture of Ireland was constituted in the reign of queen Anne, and met for the first time in the beginning of the year 1710. It has always been composed of the principal personages of Ireland and Great Britain, who were entitled the trustees of the linen manufacture of Ireland. A system of laws was framed for the regulation of the linen manufactures, and the prevention of fraud, which for wisdom, penetration, and an attention which extended to the most minute articles, would do honour to the most enlightened country. Considerable sums (from £18,000 to £25,000 per ann.) was intrusted by parliament to the distribution of the trustees in premiums, for extending and encouraging the linen manufacture. Under this auspicious influence it flourished and grew apace, whilst every day new proselytes to industry were induced to take shelter under its benignant shade.

The following table exhibits the amount of linen and linen yarn exported from Ireland to all parts of the world from 1710 to 1823, with the official value of the same.

GRAND TOTAL OF THE LINEN EXPORTED.					
Grand Total from the Year	Linen.		Official Value of Linen Exported.		
	Plain and Coloured.	Yarn.	Plain and Coloured.		Total Official Value.
			L.	Yarn.	
1710 to 1719	19,814,816	121,042	1,137,354	1,122,809	2,260,223
1720 to 1729	36,259,347	147,238	1,912,959	872,367	2,785,346
1730 to 1739	52,479,563	150,139	3,294,519	548,762	4,133,281
1740 to 1749	74,916,255	203,537	5,169,551	1,251,248	6,417,798
1750 to 1759	127,139,229	260,944	8,167,714	1,163,677	9,530,394
1760 to 1769	160,874,400	333,940	10,713,291	2,003,538	12,716,819
1770 to 1779	203,109,197	317,525	14,434,318	1,902,175	16,336,493
1780 to 1789	251,892,458	321,553	16,818,992	1,941,346	18,760,338
1790 to 1799	408,723,904	204,837	27,309,717	1,222,051	28,535,768
1800 to 1809	391,636,967	156,572	25,546,229	739,424	26,300,967
1810 to 1819	419,378,079	130,950	27,919,743	773,880	28,705,622
1820 to 1823	176,851,345	29,664	11,779,988	177,994	11,967,982
1710 to 1823	2,315,298,462	2,353,851	15,241,395	14,463,374	168,704,771

Distillation is another branch of industry characteristic of Ireland, but by no means attended with the same happy effects. It has hitherto been carried on chiefly in defiance of the revenue and government, and has given birth to a vast system of contraband, equally destructive of morals and of public order. All the mountains, bogs, and deep valleys of the north and west abound with illicit stills, in spots where the most diligent search can scarcely discover them; and where detected, they can scarcely be seized without the aid of an armed force. When the troops are seen advancing, concerted signals are made, and the small light stills are soon conveyed to a distant quarter. The farmers and proprietors encourage illicit distillation as the most ready mode of affording a market for their grain. The quality of the spirit was long much superior to that produced by the legal distillers, owing to the injudicious restrictions imposed on the latter; so that, in selling, it was considered the highest possible recommendation to give assurance that it "never paid duty." Even in the regular distilleries established in the great cities, Mr Wakefield gives reason to think that, through a purchased collusion on the part of the officers, not more than half the produce paid duty. He calculates the entire loss on them to be £856,000, and that on the illicit distillation nearly as much; so that, instead of a revenue of £2,280,000, which ought to have entered into the treasury, the amount was only £664,000. The most rigorous laws were enacted in vain, for they only rendered the people concerned in this practice more desperate and determined. Of late, however, the system has been entirely new-modelled; the duty, as in Scotland, has been reduced to two shillings a gallon, and free exportation permitted; and the strictest measures have been taken to put a stop to abuses in the collection of the revenue. The effect has been remarkable; the quantity of spirits paying duty, which from 1818 to 1822 varied from 3,000,000 to 4,000,000, rose in 1824 to 7,800,000, and in 1832 to 8,657,000; thus warranting a presumption that the contraband fabrication of this article has been greatly diminished; yet doubts may be entertained if the cheapness of a commodity of which the excess is so pernicious be on the whole beneficial to the country.

The killing and salting of beef and pork for sale forms a great branch of Irish commerce. During the American war, the number of oxen and cows slaughtered amounted to about 50,000 annually; but Mr Wakefield supposes them reduced in 1808 to about 18,000; partly owing to the extended tillage, and partly to the great increase in the export of live cattle. Each animal is found to produce upwards of

six cwt. of beef, seven stones of tallow, and nearly one cwt. of hide. The despatch with which the animals are slaughtered, the meat cut up and salted, and afterwards packed, is astonishing. The beef is packed in three different forms, called planter's beef, India beef, and common beef; the first two having the coarse pieces taken out, and charged four shillings additional per cwt. While the export of salt beef has diminished, that of pork has of late been much extended.

The cotton manufacture, since 1822, has spread through Ireland in a very surprising manner, particularly in the counties of Antrim, Down, Louth, and part of Dublin. The coarser linen fabrics are disappearing before it, and proceeding to the westward and southward, retaining still an equal hold of the kingdom in general. More recently this fabric has rather declined, and linen has regained the ascendancy.

Fishery is a branch of industry for which the extended shores and deep bays of Ireland would be peculiarly adopted. Nor do the inland waters, the rivers and lakes, less abound in the species of fish appropriate to them. The diligence of the Irish in taking fish for immediate consumption is considerable, being urged on by the frequent abstinence from other food which their Catholic profession enjoins. Their trout and salmon are distinguished both for size and taste: the salmon are caught by weirs, stake-nets, and other contrivances, but with so little precaution that their number has been sensibly diminished. The eels also are delicate and attain a great size; and the use of eel-weirs, a practice but partially known on this side of the Channel, is very general. These processes, however, do considerable injury by flooding the adjoining lands. Dublin, and the other great towns, obtain a regular supply of sea-fish, though at prices so high as to place the consumption beyond the reach of the lower orders. The curing of fish has made very little progress, when compared with the opportunities which the coasts of Ireland afford. In 1809, parliament appointed a board of commissioners for the promotion of Irish fisheries, placing at their disposal a sum of £5000 to be employed in erecting small piers, fitting out commodious boats, and providing other facilities. Since that time, the curing of fish has made considerable progress, though Ireland still cannot come into any sort of competition with Scotland. In 1824, the herrings produced by the coast fishery amounted to 34,201, on which was allowed a bounty of £6726. The open sea fishery produced 7638 barrels, on which a bounty was given of £17,300. There were also cured 2934 cwt. cod, 2645 cwt. ling, 9500 cwt. hake. The last is chiefly caught on the coasts of Waterford and Cork. There is supposed to be a most extensive bank, extending from its western coast as far as Newfoundland.

**Commerce.**—With the exception of the linen manufacture, the manufactured products of Ireland are quite inconsiderable. She has, however, very great facilities for the production of raw materials; and it is in all respects more suitable for her, as well as for England, that she should direct her efforts to this department, and import manufactured articles from Britain, than that she should attempt to enter into an unequal competition with the latter in manufacturing industry. Previously to 1806, there were several restrictions on the importation of corn from Ireland into England; but these were wholly abolished, and since that epoch her exports of corn to this country have increased from less than 400,000 to above 2,600,000 quarters! In 1825 the other restraints on the intercourse between Ireland and Great Britain were mostly abolished; and owing to this circumstance, and to the establishment of a regular inter-

course by steam packets between Liverpool, Glasgow, Bristol, and the principal towns on the east and south coasts of Ireland, the trade between the two countries has been vastly increased. This has been productive of much advantage to both parties, but principally to Ireland; and, notwithstanding the agitation of which she is the prey, it is not to be doubted that she has made very considerable advances in the way of improvement within the last half dozen years. Owing to the trade between the two countries being now placed on the footing of a coasting trade, no account has been kept, later than 1825, of the reciprocal imports and exports of each, except in the case of corn.

The shipping interest of Ireland is on a very small scale when compared with that of the sister island. On the 31st December, 1830, she had 1424 vessels; the tonnage of which was 101,820, navigated by 774 men and boys. In 1832 there were built twenty-five ships, of 1909 tons. There were entered inwards, in 1831, 14,499 ships, of 1,420,362 tons; outwards, 9801 ships, 1,073,545 tons. Of these were employed in trade with Great Britain, 13,584 ships, and 1,262,221 tons, inwards; 9029 ships, 921,128 tons, outwards; in foreign trade, 915 ships, 158,161 tons, inwards; 772 ships, 152,417 tons, outwards.

**Church.**—The conversion of the Irish to Christianity is generally ascribed to St Patrick, a native of Scotland, who is said to have received his mission from pope Celestine, and to have been raised to the archiepiscopal chair of Armagh. It appears that till the twelfth century, the pope had no authority in Ireland, (Ledwich, p. 78.), and that long before that time, a regular hierarchy had been established there, with numerous bishops; every church almost having one, besides those which were appointed to each see. The learned antiquary Ledwich remarks, that until the arrival of the English in Ireland, the number of its sees, and the succession of its bishops, as well as the history of its ecclesiastical affairs, are involved in great obscurity.

The number of clergymen of the established church consisted of 1,700, viz., 4 archbishops, 19 bishops, 33 deans, 24 archdeacons, 500 canons, prebends, &c. The total dignitaries bring 667, and working clergy 1,113. Total general, 1,700. By an act, however, recently passed, two archbishoprics are to be converted into bishoprics, and ten bishoprics are to be abolished. The aggregate revenue of the ecclesiastical establishment of Ireland is estimated by several authors, as not exceeding £1,000,000 per annum.

The Roman Catholic church of Ireland is composed of four archbishops and twenty-two bishops. The archbishops take their titles, as in the established church, from Armagh, Dublin, Cashel, and Tuam. Of the bishops eight are suffragans of Armagh, and are those of Ardagh, Clogher, Derry, Down and Connor, Drogheda, Kilmore, Meath, and Raphoe. Dublin has but three suffragans, Leixlip and Ferns, Kildare, and Ossory. Six are suffragans to Cashel, viz., Ardfer and Aghadoe, Clonfert, Ross, Cork, Killaloe, Limerick and Waterford, and Lismore. Four are subject to Tuam, viz., Achery, Clonfert, Elphin, and Killalla. There is besides the bishop of the united dioceses of Kilmacduagh and Kilfenoras, the one in Connaught, the other a Munster, who is alternately suffragan of Tuam and Cashel. As in the established church, there is also a dignitary in Galway called a *Warden*, who has nearly episcopal jurisdiction, and is no farther subject to higher powers than that he is liable to the triennial visitation of the archbishop of Tuam. Every bishop has a vicar-general of his own appointment, who holds his office only *durante vacante*, and whose jurisdiction ceases on the death of the

prelate. Every diocese has also a dean, who has the peculiar direction of all ecclesiastical matters appertaining to Ireland, and also an archdeacon, named by the bishop. These are two mere nominal dignities, having neither power nor emolument annexed to them. On the death of a bishop, the clergy of the diocese are empowered by the canon law to elect a *vicar capitular*, who is invested, during the vacancy of the see, with episcopal jurisdiction; but if such election does not take place within a specified number of days after the demise of the bishop has been notified to them, the archbishop of the province may appoint of his own authority, the vicar. The clergy, in the mean time, assemble, and fix their choice on one of their own body, or sometimes on a stranger, that he may be appointed to the vacant see. The bishops also of the province consult each other, and unite in presenting two or three men of merit, one of whom is usually appointed. The appointment of the Irish bishops takes place on Monday, and on the following Sunday is submitted to the pope, who may confirm or annul the nomination at will.

The parish priest is supported by voluntary contributions, if that can be called voluntary which is established by ancient custom and general prevalence. His income springs from various sources. From *Easter and Christmas* dues. These consist in a certain sum paid by the head of every family to the parish priest for his support, and in consideration of his trouble in catechising, instructing, and hearing the confessions of his family. The sum is greater or smaller in proportion to the circumstances of the parishioner. In the country parishes it is generally a shilling at Easter, and a shilling at Christmas; some give half a crown, some a crown, and some few a guinea a year. There is no general ecclesiastical law to enforce the payment of these trifles; but as the mode was struck out in what has been denominated the council of Kilkenny, under Rinnuccini, it has continued ever since to be practised, and from custom has acquired the force of law. The sum to be paid at weddings is different in different dioceses. The parochial fee for each christening is two shillings or half a crown, besides which the sponsors usually give something more. Some trifle is generally given for visiting the sick; a shilling usually in the country.

The estimate of the income of clergymen who are not of the established church amounts annually to £264,000, and the number of clergymen, 2,378, at an average of £110 each. The number of hearers is 6,600,000, computed as follows: Catholics, 5,500,000 Presbyterians, 800,000, and Methodists and other sects, 300,000. The places of worship amount to 2,378. The number of all the clergymen is thus given in the Dublin Evening Post, of 14th March, 1822. Catholic clergy, 1,994—Presbyterian 239, and other sects 145. Total clergymen, 2,378. And the established church clergy 1,697. Grand total of all sects of clergymen, 4,075.

In some parts of the country custom has established, that a certain quantity of hay and oats is sent by the more opulent parishioners to the clergyman, that his turf should be cut, his corn reaped, his meadow mowed, &c., gratis. The general stipend of the curate is the third part of the general receipts of the parish; but in some instances he receives half the parochial emoluments.

The following is a statement of the incomes of the dignitaries of the Established Church.

	Gross Income.	Net Income.
Archbishop of Armagh,	£13,169 16 7	£9,994 0 3
— of Dublin with Kildare,	9,320 12 9	7,746 18 0
Bishop of Meath,	5,220 10 0	4,068 10 7
— of Down, Connor, and Dromore,	5,806 0 7	4,201 17 3
— of Derry and Raphoe,	8,033 3 9	5,969 3 6
— of Kilmore, Armagh, and Elphin,	7,477 17 0	6,225 9 8
— of Ferns, Leighlin, and Ossory,	6,550 2 10	5,730 15 5
— of Cabel and Emly, Waterford and Lis-		
more,	7,354 2 0	6,308 5 2
— of Limerick, Ardfer, and Aghadoe,	5,368 13 5	4,973 9 1
— of Cork, Ross, and Cloyne,	5,008 18 10	4,091 7 10
— of Killaloe and Killynora,	4,342 9 1	3,966 9 11
— of Tuam, Killalla, and Achonry,	5,020 1 3	4,018 17 9
Total of Archbishops and Bishops,	£84,932 6 1	£67,868 4 9

In order that the reader may have before him a full view of the present condition of church property in Ireland, we subjoin a series of Tables which have been constructed by the Clerical Society, and are founded upon authentic and ample returns. These tables show how little ground there is for the assertion that the clergy of the established church are paid chiefly by the Roman Catholic population. The proportion of composition to which Protestant property is liable exceeds nearly twenty times that which is payable out of lands of which the fee is in Roman Catholic proprietors.

TABLE FIRST.

Total No. of benefices.	No. of benefices for which returns have been received.	Total No. of acres.	Total amount of composition.	No. of acres belonging in fee to Protestants.	Amount of composition thereupon.	No. of acres belonging in fee to Roman Catholics.	Amount of composition thereupon.
1,412	1,077	11,762,854	£459,324 13s. 0½d.	11,047,807	£438,423 3s. 11½d.	715,047	£20,901 9s. 1d.

TABLE FIRST CONTINUED.

Total No. of Tithe-payers.	No. of acres. Liability undertaken by the landlords.	Amount of composition thereupon.	No. of payers thus struck off.	No. of acres. Liability devolved upon the landlords.	Amount of composition thereupon.	No. of payers thus struck off.	Total No. of acres either undertaken or devolved.
280,146	2,169,133	£68,102 19s. 0½d.	100,869	1,111,513	£38,728 17s. 11½d.	45,260	3,280,646

TABLE FIRST CONTINUED.

Total amount of composition thereupon.	Total No. of payers ascertained where the liability rests.	No. of acres unascertained where the liability rests.	Amount of composition thereupon.	No. of payers whose liability consequently remains doubtful.	Average per acre is
£106,831 17s. 0d.	146,129	8,482,206	£352,492 16s. 0½d.	234,019	d. 9½ 4p682 100000

TABLE SECOND.

No. of benefices whose income has been always paid, and is likely to continue so from the undertakings of the landlords and liability devolving, &c.			No. of benefices whose payment has ceased, owing to the direct interference of the late government, Lord Althorp's speech.			No. of benefices whose payment has ceased, owing to the action of priests, local magistrates, &c. &c.		
Benefices.	Acres.	Composition.	Benefices.	Acres.	Composition.	Benefices.	Acres.	Composition.
321	4,389,636	£128,922 19s. 8½d.	58	642,001	£25,543 19s. 9½d.	524	5,539,931	£220,739 1s. 2d.

TABLE THIRD.

No. of benefices averaging 4d. per acre and under.				No. of benefices exceeding 4d., and not exceeding 6d. per acre.		
Benefices.	Acres.	£	s. d.	Benefices.	Acres.	£ s. d.
105	2,435,179	25,968	9 7	55	1,739,575	26,489 6 6½

TABLE THIRD CONTINUED.

No. of benefices exceeding 6d., and not exceeding 1s. per acre.				No. of benefices exceeding 1s., and not exceeding 1s. 6d. per acre.		
Benefices.	Acres.	£	s. d.	Benefices.	Acres.	£ s. d.

**Government.**—The government of Ireland, before the Union, was formed strictly on the model of that of Great Britain; the lord-lieutenant representing, in a great measure, the person of the king, and the houses of lords and commons being exactly similar to that of the British. Since the Union, a near approach has been made to the system by which the affairs of Scotland were regulated on the like occasion; but advantages have been conceded to Ireland in the representation, and in the establishment of a court, with a resident viceroy.

The first establishment of the office of viceroy of Ireland is to be found in the reign of Henry II.; but when the extension of British power in Ireland rendered such an officer permanently necessary, it was provided by a statute.

#### LORD LIEUTENANTS OF IRELAND FROM 1361 TO 1835.

1361 Lionel, earl of Ulster	1715 Nov. 1st, Charles Fitzroy, duke of Grafton
1371 Edmund Mortimer, earl of March	1716 Charles lord viscount Townshend
1378 P. Courcy, lord lieut., but the lord Bergham general	1721 March 31st, Charles Paulet, duke of Bolton
1381 Robert de Vere, earl of Oxford, &c.	1721 August 28th, Charles Fitzroy, duke of Grafton
1381 King Richard II., in person	1724 Oct. 22nd, John lord Carteret
1387 Roger Mortimer, earl of March and Ulster	1721 Sept. 11th, Lionel, Cranfield, Seckville, duke of Dorset
1387 King Richard II., in person (second time)	1727 Sept. 7th, William Cavendish, duke of Devonshire
1391 Thomas, earl of Lancaster	1745 August 31st, Philip Stanhope, earl of Chesterfield
1391 John, duke of Bedford	1747 Sept. 13th, William Stanhope, earl of Harrington
1391 Edward, earl of March	1751 Sept. 9th, Lionel, Cranfield, Seckville, duke of Dorset
1415 John Talbot	1755 May 26th, William Cavendish, marquis of Harrington
1415 Thomas, earl of Lancaster	1757 Sept. 25th, John Russell, duke of Bedford
1415 Sir John de Grey	1761 Oct. 6th, George Dunk, earl of Halifax
1415 Sir J. Vernon, lord Dudley	1763 Sept. 22nd, Hugh, earl of Northumberland
1415 Sir Thomas Stanley	1765 Oct. 18th, Francis, earl of Hertford
1415 Lord and Wells	1767 Oct. 14th, George lord viscount Torrington
1415 James, earl of Ormond (first time)	1772 Nov. 26th, Simon Harecourt, earl of Harecourt
1415 James, earl of Shrewsbury	1772 Jan. 25th, John Hobart, earl of Buckinghamshire
1415 Edward, duke of York	1772 Dec. 23rd, Frederick Howard, earl of Carlisle
1415 Prince Edward, son to Richard III.	1778 April 14th, W. H. Cavendish, duke of Portland
1415 John de Pals, earl of Lincoln	1778 Sept. 15th, George Nugent, Grenville Temple, earl of Temple
1415 Jaeger, duke of Bedford	1778 June 2nd, Robert Henly, earl of Northampton
1415 Gerald, earl of Kildare (first time)	1778 Feb. 24th, Charles Manners, duke of Rutland, died 21st Oct. 1787
1415 Henry, duke of York, afterwards Henry VIII.	1787 Dec. 16th, George Nugent, Grenville Temple, marquis of Buckingham
1415 Gerald, earl of Kildare (second time)	1790 Jan. 6th, John Fane, earl of Westmoreland
1415 Thomas Howard, earl of Surrey	1794 Earl Fitzwilliam
1415 Henry, duke of Richmond	1795 Earl Camden
1415 Thomas, earl of Sussex	1796 Marquis Cornwallis
1415 Robert, earl of Essex	1801 May 24th, Philip, earl of Hardwicke
1415 Sir Charles Blount, lord Mountjoy	1802 Earl of Powis, (did not go over)
1415 Thomas, lord viscount Wentworth, earl of Stafford	1802 March 20th, John, duke of Bedford
1415 James, marquis of Ormond	1807 April 19th, Charles, duke of Richmond
1415 James Butler, duke, marquis and earl of Ormond	1815 August 26th, Charles viscount Whitworth
1415 John Roberts, lord Roberts	1817 Oct. 9th, Charles, earl of Talbot
1415 Butler, lord Berkeley	1821 Dec. 29th, Marquis of Wellesley
1415 Sir Capt. earl of Essex	1827 July do. do. do.
1415 James Butler, duke of Ormond	1829 Duke of Northumberland
1415 Henry Hyde, earl of Clarendon	1831 Marquis of Anglesey
1415 Richard Talbot, earl of Tyrconnel	1834 Marquis of Wellesley
	1834 Earl of Harrington
	1835 Earl Mulgrave

The lord lieutenant of Ireland corresponds with the secretary of state for the home department, by whose directions he is supposed to regulate his conduct; his salary amounts to £27,000 per annum. His residence is in Dublin castle, built in 1220. The officers of the lord lieutenant's household are a private secretary, a steward, a comptroller, a chamberlain, a gentleman usher, a master of the horse, with gentlemen of the chambers, pages, &c.

Ireland has a privy council, of which the chief officers of state are members. The lord lieutenant is president. The number of members of the privy council is between fifty and sixty. Next to the lord

lieutenant the secretary is considered the principal efficient officer.

**Revenue.**—The revenue of Ireland is small. With a population of nearly one half of Great Britain, the revenue seldom exceeds five million pounds, or not one-twelfth of the total revenue of the former, while the expenses and charges upon collection are much greater in proportion. In January, 1817, the exchequer of Ireland was united with that of Great Britain, and the charge for interest and management on the loans raised in England was consolidated with the public debt on that date.

**Social State.**—Since the year 1825, five parliamentary committees have sat on the state of Ireland, and have published five folio volumes on the subject. Much information has also been recently laid before the public by the travels and investigations of private individuals. And from all sources, abundant evidence is brought to prove, that a great amount of crime and misery prevails even at this day over the country. In 1833, there were 17,800 crimes perpetrated in Ireland, for which persons were committed to jail. In England, if there had been the same ratio between crime and population, there should have been 34,000 crimes: there were only 20,000. In Scotland, there should have been 4,000: there were but 2,000. A great proportion of these crimes consisted of personal acts of violence or outrage, arising from the brawls of factions, or disputes about the possession of lands. "A small Irish county town, during assizes," says Mr Inglis, who travelled through Ireland in 1834, and who has published a very sensible and dispassionate book on the subject, "presents a spectacle that is never seen in England; for even supposing the calendar to be as long, in an English as in an Irish county,—which it never is,—the difference in the character of the cases to be tried, materially affects the aspect of the town and its population. In England, a case of murder or manslaughter, brings to the county town only the near relations of the party to be tried,—and perhaps, of the party prosecuting; but in Ireland, things are on a different scale. The English murder is a private act, perpetrated by some ruffian for the sake of gain: the Irish homicide has been committed for no reason at all; and not by one cold-blooded ruffian, but by a crowd of demi-barbarians, who meet for the purpose of fighting; and who have no other reason for fighting, than because one half of the number are called O'Sullivan, and the other O' something else; so that when a manslaughter is to be prosecuted at an Irish assize, the case does not bring up merely the accused and his one or two witnesses; but it brings half the "boys" in the county who bear the same name as the accused; and as many more, of the same name as the man who was killed,—every one of the former, ready to kiss the book, and swear, that the boy accused of the homicide, never handled a shillelah, or lifted a stone, or was seen in a "scrimmage" in his days; and every one of the latter as ready to swear, that the boy that was killed, was the most peaceable boy that ever bore his name, and that he was killed for no reason at all. Besides these homicide cases, which are peculiar to an Irish assize, prosecutions of any kind bring together a greater number of persons than in England,—for be it a robbery, or a rape, or any other crime, of which a man is accused, all his relations come forward to swear an alibi. It may be easily conceived, therefore, what a motley crowd fills the streets of an Irish county town at the time of an assize. The most numerous class of cases at most Irish assizes, is that which is facetiously denominated *fair murders*; that is, homicides committed at fairs; and I do not know any means, by

which so much insight is to be obtained into the character of the Irish peasantry, and into the condition of the country, and state of things among the lower classes of society, as by listening to these prosecutions for *fair murders*. There were many of these prosecutions at the Ennis assizes; and, although I had already heard much of the factions, into which the peasantry are divided, I had no conception of the extent of this evil, nor of the bitterness with which this spirit of faction is attended. However these factions may have originated, there is now no distinction among their adherents, excepting that which arises from the possession of a different name. The O'Sullivans are as distinct a people from the O'Neils as the Dutch from the Belgians. The factions have chiefs, who possess authority. Regular agreements are made to have a battle; the time agreed upon is generally when a fair takes place; and, at these fights, there is regular marshalling, and "wheeling;" and, as for its being a crime to break a "boy's" head, such an idea never enters the brain of any one. The spirit of faction is brought into court by almost every witness in these prosecutions. I saw a witness, a woman, brought in support of the prosecution for a homicide committed on some cousin, who, on being desired to identify the prisoners, and the court-keeper's long rod being put into her hand, that she might point them out, struck each of them a smart blow on the head. As for finding out the truth, by the mere evidence of the witnesses, it is generally impossible. Almost all worth knowing, is elicited on the cross-examination; and it is always by the appearance and manner of the witness, more than by his words, that the truth is to be gathered. All the witnesses, examined for the prosecution, were, by their own account, mere lookers-on at the battle; nor stick, nor stone had they. *Their* party had no mind to fight that day; but, in making this assertion, they always take care to let it be known, that, if they had had a mind to fight, they could have handled their shillelahs to some purpose. On the other hand, all the witnesses for the prisoner aver just the same of themselves; so that it is more by what witnesses won't tell, than by what they do tell, that truth is discovered. Half the witnesses called, on both sides, have broken heads; and it is not unfrequently by a comparison of the injuries received on both sides, and by the evidence of the doctor, that one is helped to the truth. To save a relation from punishment, or to punish any one who has injured a relation, an Irish peasant will swear anything. This would be called, by some, hatred of the law; but, although, in swearing falsely, the Irish peasant wishes to defeat the ends of justice, he does not do so merely because he hates justice and the law, but because he thinks he is bound to save his relation, or any one of his faction. If the name of the man who was killed be O'Grady, then every witness who comes up to be sworn for the prosecution is also an O'Grady; or, if they be women, they were O'Grady's before they were married; and, if the name of the prisoner be O'Neil, then all the witnesses for the defence are O'Neils; or, if there be any exceptions in name, still there is a relationship of some kind."

But the destitution and misery existing among the Irish peasantry is still more appalling than the extent of crime. "The great mass of the labouring class in Ireland," (to use the same authority), "have no constant employment. Throughout the greater part of Leinster, Munster, and Connaught, a large majority of the labouring poor are unable to find constant employment. With the exception of Belfast, and in some few places where public works had created a temporary demand, I found nowhere full

employment for the people. As for their means of subsistence, when out of employment, little better. If they have not, themselves, a patch of potato land, they, or their wives, beg among the farmers round the country; relations, who have a little to spare, help them; and the priest also does something for them. The diet of those who are in employment consists of a scanty meal or two of potatoe, with, in addition, at times, of a little buttermilk. The one of the far greater number who are not in employment, consists of as many dry potatoes as serve just to sustain life. In Ulster, things are rather better: there are fewer of the latter class; and the farmers have more plentiful meals. As for clothing, an English beggar would not lift off the ground the clothes worn by old and young of the lower classes of Leinster, Munster, and Connaught. The young can scarcely be said to be clothed at all. Everywhere, the large towns, such as Belfast, Cork, and Limerick, and the labour employed on the domains of a very few resident noblemen, penance, without diet, at the highest wages ever given for constant employment: ninepence and eightpence is the more usual rate; and, in some places, sixpence is willingly accepted, for constant employment. With constant sixpence is the usual sum given. The wages of occasional employment vary with the occasion: in seasons of particular demand, one shilling, or more, even, may be given; but, at all other times, the number of labourers may be hired, by the week at eightpence, and even lower. The labour of women and children is scarcely wanted, where half the male population are unemployed. Women employed in agricultural labour, are generally some part of the family of the landholder. Where not one half of the people are in constant employment, it would be unfair to state the average amount of employment obtained by a labourer throughout the year, to be more than for one half of the year: during that half-year, his wages cannot be fairly stated at more than 8d. for four months; and for the other two months, seed and harvest times, 1s. The hundred and ten working days, at 8d. are £3 9s. 4d.; and the first two days, at 1s.; added to this, make £6 1s. 4d. which is all the labourer, obtaining an average amount of employment, may earn in a year: this sum, divided by 365—the number of days what the labourer has to support himself and his family—gives him, per day, not quite fourpence! I am very confident, that if the whole yearly earnings of the labourers of Ireland were divided by the whole number of labourers, the result would be under the sum,—fourpence a day for the labourers of Ireland. Early marriages and a numerous progeny are universal. If the labourer has four children also to work, the probability is, that he has at least two younger children to support: the occasional labour and scanty remuneration paid for the labour of a child, will certainly not do more than suffice for its own support throughout the year; and when we consider the general dearth of employment, and the large families of the Irish peasants, we may fairly conclude, that the labourer has to support himself and two children by his own labour, which we have seen averages 4d. per day. With respect to the yearly expense of food, two stone and a half of potatoes, no more than suffice for the daily support of a labourer, his wife, and two children; not taking the average price of potatoes at 3d. per stone, a very low average, mere subsistence cannot be purchased with the whole amount of wages, supposing the whole amount available for subsistence: but rent has to be paid. Formerly the pig was sufficient for this; but the market has so fallen, that something is wanted besides the pig to make

up the rent. Where no land is attached to the cabin, the average rent of it being 35s., at least 20s. of this sum must be made up from wages; so that the 4d. per day suffers a diminution of nearly three farthings. Where a little potatoe land is attached to the cabin, the value of the potatoes may be considered an equivalent for the amount of the rent. In the country, the landlords of cabins are generally small farmers, who are quite as hard set to make up their own rent, as their humbler dependents are to pay theirs. In the suburbs of the towns, great landowners, and often noble lords, are the landlords. In Wicklow, Wexford, Waterford, Kilkenny, and Tipperary counties, 30s. and 40s. is the usual rent of a cabin, either altogether without land, or with so inconsiderable a patch, that its value is scarcely any set off against the rent. In the more western and more northern parts of Ireland, with the same rent, a little potatoe land generally accompanies the cabin, excepting in the suburbs of the towns. The only difference between the best and the worst of the mud cabins, is, that some are water-tight and some are not; air-tight I saw none; with windows, scarcely any; with chimneys, that is, with a hole in the roof, for the smoke to escape through, as many, perhaps, with it as without it. As for furniture, there is no such thing; unless a broken stool or two, and an iron pot, can be called furniture. I should say, that in the greater part of Leinster and Munster, and in the flat districts of Connaught, bedsteads are far from general; and bed clothing is never sufficient. In the greater part of Ulster, cabins, and their furniture, are considerably superior."

This is a most melancholy picture of a people starving in a land of fertility—a land surpassed by no other in its physical adaptation both to agricultural and commercial purposes. Into the causes of the condition of Ireland, it would be difficult to inquire in a limited space. Hundreds of volumes have been written on the subject, and thousands of speeches spoken. It has been the leading theme of every magazine and review since the beginning of the century, and the favourite topic of every orator; yet the question is still unsettled. The most popular method of accounting for the miseries of Ireland used to be to attribute them all to the injustice or oppression of the British government; but however much Ireland may have suffered from England in former days, she has now little cause of complaint against this country. She is much more moderately taxed than Britain, and the parliamentary grants annually bestowed on her much exceed the proportion of those bestowed on any other part of the empire. Ireland, in short, for many years back, has received almost the exclusive patronage of both Tory and Whig administrations, and its interests have occupied more of the attention of parliament and the press than the interests of all the rest of the empire put together. The only public evil of which the Roman Catholic part of the population have now to complain is the exaction of tithes for the support of a Protestant clergy; but, as will be seen from tithes given in a previous page, the Catholics, in reality, have all along borne a very slender portion of this burden, and of late years have refused altogether to pay their modicum, in which refusal government has acquiesced. The entire abolition of tithes in Ireland would do good, in as far as it might tend to lessen the asperities which exist between Protestants and Catholics; but it is questionable if it would be otherwise beneficial to the country. The landlords would receive the sole advantage of it; for it is evident, that the rental of land would rise in proportion to the removal of the burden, and the

only change would be, that the tithe, instead of going into the pockets of a resident clergyman of character and education, disposed to look after the interests of the people, would go into the pockets of absentee landowners, the great body of whom have ever shown the utmost indifference regarding the welfare or comforts of their tenantry. Where, then, are we to look for the causes of that extent of crime and misery which unhappily characterizes the condition of Ireland, and where for the remedies? One of the great causes of the disturbances which take place in Ireland is the animosity which exists between Protestants and Catholics, or Orangemen and Ribbonmen. In England and Scotland, fortunately, no such animosity exists, or is limited to very small sections of zealots; but in Ireland, the feeling is universal, and often breaks out in acts of open hostility. Whatever might tend to soothe this feeling—to eradicate the unchristian spirit with which Catholics and Protestants there view each other—would be conducive to the peace and consequent prosperity of Ireland; but so far from any means being adopted to this end, it seems to be the object of the leading men of both parties to aggravate the feeling, and even to extend its baleful influence into England and Scotland, by the establishment of hostile associations.

The numerous factions into which the peasantry of Ireland is divided—factions independent of religious or political feeling—prove, also, prolific sources of outrage and disturbance. As in Scotland, in former times, these factions are generally only distinguished from each other by family surnames: the O'Sullivan's, the O'Neils, the O'Grady's, the Macshanes, and the like, consider themselves as distinct people, and would hold it very unbecoming to meet at a fair or a funeral without a fight. More bloodshed, according to Mr Inglis, and more savage brutalities arise from them than from either political or religious causes. With an extended education of the people, and an increase of their comforts, there is every reason to hope that these foolish factions would speedily become extinct. One hundred years have not passed since similar factions, distinguished either by names or by parishes, were prevalent in Scotland, and nothing was more common, at fairs or markets, than to see parties belonging to different villages or districts pitted against each other, and fighting with a ferocity not to be exceeded by the Irish. Such scenes are not now to be met with; and may we not hope that, with an improved condition of the people, both physically and morally, they would become as rare in Ireland as they are in Scotland.

But one of the greatest evils of Ireland—the source of more outrage than either religious animosity or factious feuds—is the view which the peasantry entertain regarding the possession of land. "The peasantry," says Mr Barrington, a crown solicitor, in his examination before a committee of the house of commons, "have always had objects connected with the land. I have traced the origin of almost every case I prosecuted, and I find that they generally arise from the attachment to, the dispossession of, or the change in, the possession of land." The outrages of 1775 arose from associations of peasants formed to regulate the prices of land. Many of the combinations, both of the last and present century, had for their object the reduction of rent. How many instances are there of the people preventing the ejection of an old tenant, or of murdering a new comer! In 1820, the middlemen pressed on the tenantry, and they, to the number of 1500, rose in Galway, and ravaged the country. In 1821, severe exaction of rent on the Courtenay estate roused a tenant of the name of Dillane. This man was the

celebrated captain Rock, and he excited a general opposition to rent over Clare, Limerick, Kerry, and Cork. In 1822, the peasantry rose in a body for the reduction of rent; and most of the cases of outrage subsequent to that period have been connected with land. The Carders, the Righters, the Shanavats, the Caravats, the Whiteboys, the Peep-o'-day boys, the Thrashers, the Riskavallas, the Rockites, the Whitefeet, the Blackfeet, the Lady-Clares, and Terry-Alts, are all varieties of the same gang, and have all, more or less, originated in the enforcement of rents or the ejection of tenants.

In seeking for the causes of these and other evils that afflict Ireland, and that prevent it from taking that place among the prosperous and civilized kingdoms of Europe which its many natural advantages, and the warm-hearted and quick-witted character of its inhabitants, so eminently entitle it to do, the reader may be surprised to learn, that the extensive cultivation of the potatoe in that country has been considered by some economists as its greatest curse. This startling doctrine was, we believe, first advanced by Mr J. R. Macculloch; and is supported by him with so much apparent reason, that we cannot close the subject better than by quoting his own words. After demonstrating that an acre of potatoes will feed at least double the number of individuals that can be fed from an acre of wheat, Mr Macculloch proceeds to say that,

"On the most moderate estimate, the population of a potato-feeding country may become, *other things being about equal*, from two to three times as dense as it could have been, had the inhabitants fed wholly on corn. But it is exceedingly doubtful whether an increase of population, brought about by a substitution of the potato for wheat, be desirable. Its use as a subordinate or subsidiary species of food is attended with the best effects—producing both an increase of comfort and security; but there are certain circumstances inseparable from it, which would seem to oppose the most formidable obstacles to its advantageous use as a *prime* article of subsistence.

"It is admitted on all hands, that the rate of wages is principally determined by the species of food made use of in a country. Now, as potatoes form that species which is produced at the very least expense, it may be fairly presumed, on general grounds, that wages will be reduced to a minimum wherever the labouring classes are mainly dependent on potatoes; and the example of Ireland shows that this conclusion is as consistent with fact as with principle. It is clear, however, that when the crop of potatoes happens to be deficient in a country thus situated, the condition of its inhabitants must be in the last degree unfortunate. During a period of scarcity, men cannot go from a low to a high level: if they would elude its pressure, they must leave the dearer, and resort to cheaper species of food. But to those who subsist on potatoes this is not possible; they have already reached the lowest point in the descending scale. Their wages being determined by the price of the least expensive sort of food, they cannot, when it fails, buy that which is dearer; so that it is hardly possible for them to avoid falling a sacrifice to absolute want. The history of Ireland abounds, unfortunately, in examples of this sort. Nothing is more common than to see the price of potatoes in Dublin, Limerick, &c., rise, because of a scarcity, to five or six times their ordinary price, and the people to be involved in the extreme of suffering; and yet it rarely happens, upon such occasions, that the price of corn is materially affected, or that any less quantity than usual is exported to England.

"It may be said, perhaps, that had potatoes not been introduced, wheat, or barley, or oats, would

have been the lowest species of food; and that whenever they happened to fail, the population would have been as destitute as if they had been subsisting on potatoes. It must, however, be observed, that the proportion which the price of wheat, or any species of grain, bears to the price of butcher's meat, tea, beer, &c., is always decidedly greater than the proportion which the price of potatoes bears to these articles: and it therefore follows, that a people, who have adopted wheat, or any species of corn, for the principal part of their food, are much better able to make occasional purchases of butcher's meat, &c., and will consequently be more likely to have their habits elevated, so as to consider the consumption of a certain quantity of animal food, &c. as indispensable to existence. And hence it appears reasonable to conclude, that a people who chiefly subsist on corn, would, in most cases, subsist partially on butcher's meat, and would enjoy a greater or less quantity of other articles: so that it would be possible for them, in a period of scarcity, to make such retrenchments as would enable them to elude the severity of its pressure.

"But though the population in corn-feeding countries were dependant on the cheapest species of grain, not for a part only, but for the whole of their food, their situation would, notwithstanding, be less burdensome than that of a population subsisting wholly on potatoes.

"In the *first* place, owing to the impossibility, as to all practical purposes at least, of preserving potatoes, the surplus produce of a luxuriant crop cannot be stored up or reserved as a stock to meet any subsequent scarcity. The whole crop must necessarily be exhausted in a single year; so that when the inhabitants have the misfortune to be overtaken by a scarcity, its pressure cannot be alleviated, as is almost uniformly the case in corn-feeding countries, by bringing the reserves of former harvests to market. Every year is thus left to provide subsistence for itself. When, on the one hand, the crop is luxuriant, the surplus is of comparatively little use, and is wasted unprofitably; and when, on the other hand, it is deficient, famine and disease necessarily prevail.

"In the *second* place, the general opinion seems to be, that the variations in the quantities of produce obtained from land planted with potatoes, are greater than the variations in the quantities of produce obtained from land on which wheat, or any other species of grain, is raised.

"And *lastly*, owing to the great bulk and weight of potatoes, and the difficulty of preserving them on shipboard, the expense of conveying them from one country to another is so very great, that a scarcity can never be materially relieved by importing them from abroad. In consequence, those who chiefly depend on potatoes are practically excluded from participating in the benevolent provision made by nature as equalizing the variations in the harvests of particular countries by means of commerce, and are thrown almost wholly on their own resources.

"We should, therefore, be warranted in concluding, even though we were not possessed of any direct evidence on the subject, from the circumstance of the potato being a crop that cannot be kept on hand, from its natural fickleness, and from the incapacity of importing it when deficient, or of exporting it when in excess, that the oscillations in its price must be greater than in the price of wheat; and such, as point of fact, is the case. The oscillation in wheat is thought great when its price is doubled; but in a scarce year the potato is not unfrequently as dear as in a plentiful one! And the comparatively frequent recurrence of scarcities in Ireland, and the destitution and misery in which they involve the

population, afford but too convincing proofs of the accuracy of what has now been stated.

"It is, therefore, of the utmost consequence to the well-being of every people, and to their protection in years of scarcity, that they should not subsist principally on the potato. In this country the pressure of a scarcity is evaded by resorting to inferior species of food, such as potatoes, and a lower standard of comfort; but if our people were habitually fed on the potato, this would be impracticable. The chances of famine would thus be vastly increased; while, owing to the low value of the potato as compared with most other things, the labourers would have less chance of preserving or acquiring a taste for animal food, or other necessities and luxuries; and, consequently, of changing, at any future period, their actual condition for a better."

**Population.**—The reader will find in the table at page 126, a list of the population of the various counties of Ireland. By a recent Report of the Commissioners of Public Instruction, it is estimated that there are about six millions and a half of Catholics in Ireland, and one million and a half of Protestants. The Protestants are very unequally distributed; for while Ulster has 1,100,000, being about one half the entire population of that province, the other three provinces have but 400,000 Protestants in a population of above five millions.

**IRENÆUS, Sr**; presbyter, and at a later period, bishop of Lyons, towards the end of the second century, a pupil of Polycarp and Papias; a man of considerable learning, and animated with an ardent zeal for Christianity. He was violent in his opposition to the heretical Chiliasts. His works are all lost, except his *Libri V. adversus Hæreses*, and these are extant only in a translation. He suffered martyrdom (after 202), and is honoured as a saint. His day is April 6. His works have been edited by Federarient (Paris, 1596, folio), Grabe (Oxford, 1702, folio), Massuet (Paris, 1710.). His fragments have also been collected by C. M. Pfaff (Hague, 1715).

There are several other martyrs of this name, and three men of the same name are mentioned in the Greek Anthology.

**IRENE**; 1. in mythology, one of the Hours (see *Hours*), denoting peace.

2. An empress of Constantinople, alike famous for talent and beauty, and for her crimes; was born at Athens, and, in 769, married, Leo IV., after whose death, by poison administered by her, she raised herself (780), and her son, Constantine VI., who was then but nine years old, to the imperial throne, with the aid of the nobles. She believed it necessary to strengthen herself in this dignity by new acts of violence, and caused the two brothers of her murdered husband, who had formed a conspiracy against her, to be executed. Charlemagne at that time menaced the Eastern empire. Irene at first delayed him by promises. She at last went so far as to oppose him, arms in hand; but he totally defeated her army in Calabria, in the year 788. Two years before, she had convened two general councils at Nice, in which the Iconoclasts were particularly attacked. (See *Iconoclasts*.) When

Constantine had grown up, he refused to permit her to participate longer in the government, and actually reigned alone seven years, when he was arrested at the order of his mother, his eyes plucked out, and himself finally murdered. Irene was the first female who reigned over the Eastern empire. Her entrance into Constantinople on a triumphal car of gold and precious stones, her liberality to the people, the freedom which she bestowed on all prisoners, and other artifices employed by her, were not sufficient to secure her from the consequences of her criminal accession. She had ordered many nobles into banishment, and, to secure yet more firmly the possession of the throne, had just resolved to marry Charlemagne, when Nicephorus, who was placed on the imperial throne, exiled her, in 802, to the isle of Lesbos, where she died, in 803.

**IRETON, HENRY**; an eminent commander and statesman, of the parliamentary party, in the civil wars of Charles I. He was descended from a good family, and was brought up to the law; but, when the civil contests commenced, he joined the parliamentary army, and, by the interest of Cromwell, whose daughter Bridget he married, he became commissary-general. He commanded the left wing at the battle of Naseby, which was defeated by the furious onset of prince Rupert, and he himself wounded and made prisoner. He soon recovered his liberty, and took a great share in all the transactions which threw the parliament into the power of the army. It was from his suggestion that Cromwell called together a secret council of officers, to deliberate upon the disposal of the king's person, and the settlement of the government. He had also a principal hand in framing the ordinance for the king's trial, and sat himself as one of the judges. Ireton accompanied Cromwell to Ireland, in 1649, and was left by him in that island as lord deputy. He reduced the natives to obedience with great vigour, but not without cruelty. He died in Limerick, in 1651. Hume calls him a memorable person, celebrated for vigilance, capacity, and a rigid exercise of justice, during his unlimited command in Ireland. After the restoration, his body was taken up, and suspended from the gallows, with that of Cromwell, and was buried in the same pit.

**IRIA**; a Basque word, signifying *town, city*.

**IRIARTE, or YRIARTE, THOMAS D'**; a Spanish poet, born in 1752, and died in 1803. As a poet, he is known by his Literary Fables (1782), which have been translated into English, his poem *La Música* (1784, 4to.), dramas, &c. His works were published in 8 vols., at Madrid, in 1805.

**IRIDIUM**; the name of a metal discovered in 1803, by Mr Tennant, in the black residuum from the solution of the ore of platinum. Its name was bestowed in allusion to the rainbow (*iris*), in consequence of the changeable colour it presents while dissolving in muriatic acid. Its colour is white; it is brittle, and very difficult of fusion; specific gravity, 18.68. Its greatest specific gravity in the unfused state is stated by Dr Turner to be 15.8628. Berzelius estimates its prime equivalent at 98.8. Iridium is the least fusible of all metals, and the last mentioned chemist failed in all his attempts to bring it to a state of fluidity; but Mr Childrun succeeded in procuring a small globule, by means of his powerful galvanic apparatus. It is acted upon with difficulty even by the nitro-muriatic acid; but, when oxidized by digestion with it, it unites with other acids, and with the earths, particularly with alumine. It combines with sulphur, by heating a mixture of ammonia, muriate of iridium, and sulphur: the compound is a black powder, consisting of 100

iridium and 33.3 sulphur. Lead unites with this metal easily, but is separated by cupellation, leaving the iridium on the cupel, as a coarse black powder. Copper forms with it a very malleable alloy, which, after cupellation, with the addition of lead, leaves a small proportion of the iridium, but much less than in the preceding instance. Silver forms with it a perfectly malleable compound, the surface of which is merely tarnished by cupellation; yet the iridium appears to be diffused through it in fine powder only. Gold remains malleable, and little altered in colour, though alloyed with a considerable proportion; nor is it separable either by cupellation or quartation. Dr Wollaston has observed, that, among the grains of crude platinum, there are some scarcely distinguishable from the rest, but by their insolubility in nitro-muriatic acid. They are harder, however, when tried by the file, not in the least malleable, and of the specific gravity of 19.5. These he concluded to be an ore consisting entirely of iridium and osmium.

**IRIS**; daughter of Thaumass and Electra (daughter of Oceanus), the sister of the Harpies, and the fleet, golden-winged messenger and servant of the gods, especially of Jupiter and Juno, who, in reward of her services, as tradition runs, transported her to heaven, in the form of a rainbow. She is represented as a beautiful virgin, with wings and a variegated dress, with a rainbow above her, or a cloud on her head exhibiting all the colours of the rainbow. The physical appearance of the rainbow is the foundation of this fable, conformably with the custom of the Greeks. The rainbow was believed to draw vapours up to the clouds from the sea and land, and to drink up the rivers with the head of an ox. The ring of the eye, or the coloured circle around the pupil of the eye, is also called *iris*; and *iris-stones* are specimens of crystal or quartz, which exhibit the colours of the rainbow.

**IRIS, FLAG, or FLOWER-DE-LUCE**; a genus of plants comprising upwards of eighty species, remarkable for their pointed, sword-shaped leaves, and their large and beautiful flowers. They constitute one of the chief ornaments of the northern regions of the globe, and usually grow in wet places, bearing flowers of various colours, but the prevailing tint of which is blue. Nine species are natives of the United States, some of which possess active cathartic properties.

**IRKUTSK**; a Russian government in Asia, formerly containing two and a half million square miles, with a population of from 5 to 600,000 inhabitants. The present government, formed in 1823, is the eastern part of the former government; it contains 400,000 inhabitants, and reaches from 95° 40' E. longitude to the Northern Frozen ocean and the Pacific ocean, forming the Russian frontier towards China. The soil is chiefly sterile, the climate cold. The mountain chains Sayanskie and Stanovoi render the face of the country uneven. The seas of Kamtschatka and Okotsk, into which many promontories project, wash its coasts. In the warmest summer months only is navigation possible, and the communication with other countries is very much interrupted. The rivers are the Lena, Olonek, Anabara, Kolyma, Indigerka, which empty into the icy sea; the Anadyr, Kamtschatka, Argoun, Schilka, which empty into the Pacific ocean. The climate is various, but the winter is every where long. In the southern part, grain is raised, and some vegetables are produced in every district. The woods abound in bears; few cattle are raised; the reindeer are numerous, as are also sables, foxes, and sea-otters. Swarms of mosquitoes molest man and beast. The waters contain many salmon, which make part of

the food of the bears and wolves. The mineral kingdom is not destitute of precious metals, but they are little worked. The inhabitants are Russians, Tartars, Mongols, &c., in a low state of civilization. A circle of the government is also called Irkutsk, and the capital of both bears the same name. It was built in 1669, is situated on the Angara, and contains thirty-three churches, a theatre, several schools (a Japanese gymnasium, a garrison school, a seminary for priests, a printing-office, a library with 3000 volumes, &c.), soap boileries, manufactories of cloth, salt works, and has considerable commerce, as the entrepot for the fur trade with China. Population, 20,000. It is connected by its position with three commercial routes—that of Kiakta, that of eastern Siberia and Kamtschatka, and that of western Siberia and Russia. The commerce carried on here is valued at £180,000 annually. The furniture, ornaments, &c., from China, give this city a Chinese air. Lat. N. 52° 16' 41"; long. E. 104° 11' 41."

**IRMINSUL** (German *Irmensäule*); a statue worshipped by the ancient Saxons, which represented a man completely armed in the fashion of the ancient Germans, with a banner in his right hand and a lance in his left. This statue was then most sacred idol, and is said to have stood in a holy grove at Eresburg, a principal fortress of the Saxons (near the present Paderborn). Charlemagne demolished this fortress in 772, and with it that monument of antiquity. The history and meaning of the Irminsul is very obscure; according to common opinion, it was erected in honour of Herminus, the deliver of Germany (see *Arminius*); but it was probably the image of some distinguished divinity, perhaps of Woden himself, and the name of *Irmis* or *Hermann*, which signifies *man of war*, was attached to it, because Woden was the god of war.

**IRON** is the most valuable of all the metals. Though mentioned in the Pentateuch, we have reason to believe, from the facts that the fabrication of steel was unknown to the ancients, and that they were wholly destitute of metallurgical skill, that its uses were little known in the earlier periods of society. The Romans employed, as a substitute for it in their armour, an alloy of copper and tin. Its use has followed the progress of civilization in the world; and the amount of it consumed by any nation, at the present day, indicates very truly the degree of its advancement in the arts and sciences. The alchemical name of iron was *Mars*. In treating of this metal, we shall adopt the following order: its ores; their reduction to the metallic state; the chemical history of iron.

**Ores of Iron.** Iron exists in nature under four different states—the native state; that of an oxide, in combination with combustible bodies, particularly sulphur; and, finally, in the state of salts, as the sulphate, phosphate, and carbonate, of iron.

1. **Native Iron.** Natural malleable iron is a rare production of this globe, nearly all that has ever been found upon it having come to us from the atmosphere. It occurs in the form of a ramose stalactite, covered by brown, fibrous oxide of iron, mingled with quartz and clay, in a vein traversing a mountain of gneiss, near Grenoble, in France; also with spathic iron and heavy spar, at Kamedorf, in Saxony. More recently, it has been found in three places in the United States—at Canaan, in Connecticut, Pennsylvania, and North Carolina; at the latter place, it was found loose in the soil, in a mass weighing more than twenty pounds. In neither of these cases was the iron perfectly pure. That from Saxony, besides 92.50 of iron, contained 6.0 of lead and 1.5 of copper; that of Canaan was slightly

intermingled with carbon, so as occasionally to lose its malleability, approximating it to the character of steel; and that of Pennsylvania was alloyed with 1.56 per cent. of arsenic. A piece, weighing 7 oz. from the large mass of North Carolina, was crystallized in the form of the regular octahedron, the surfaces of which exhibited a plated structure: it was examined for other metals without success, though its imperfect malleability left no doubt of its containing a small proportion of arsenic. The meteoric iron differs very considerably from the terrestrial, native iron. Its colour is a light steel-gray, resembling platinum; it is easily cut with the knife, and it is flexible and perfectly malleable when cold. Specific gravity, 7.768. It occurs in large masses, sometimes of many tons weight, marked externally by impressions, like those produced by the hands and feet upon a soft, plastic mass; also in small globular and fliform masses, disseminated through meteoric stones. Occasionally, it presents imperfectly-formed octahedral crystals. A crystalline texture becomes visible, however, in cutting the large masses, and exposing the surfaces produced to the action of nitric acid, or allowing them to tarnish by heat. It invariably contains from 3 to 12 per cent. of nickel, and often traces of cobalt, neither of which metals have ever been found alloying terrestrial native iron. Meteoric iron is contained in all meteoric stones; in some, it exists in a very feeble proportion; in others, it forms one quarter of their weight; and again in others, it constitutes nearly the entire mass; while the largest masses of it ever found consist of it wholly, without the smallest mixture of foreign matters. In the two first-mentioned conditions, it has often been seen to fall from the heavens, while in the solid state, it never has been observed, by credible witnesses, to fall, but on one occasion, at Agram in Croatia. Some of the largest masses of meteoric iron known, are the following: that found by Pallas, in Siberia, weighing 1680 Russian pounds; that discovered by Rubin de Celis, in the district of Chaco-Gualamba, in South America, and which weighs 15 tons; and that found near Red River, in Louisiana, weighing 3000 pounds, and which is now deposited in the collection of the lyceum of natural history in New York. Besides these, other very considerable pieces have been noticed in Africa, Mexico, and Bohemia. Meteoric iron has been worked, as an object of curiosity, into knives, swords, and other instruments. For additional particulars concerning meteoric iron, and its origin, see *Meteoric Stones*.

2. *Magnetic Iron Ore, or Oxydulated Iron*, is of an iron-black colour, more intense than belongs to metallic iron; its powder is of a pure black. It occurs crystallized, in the form of the regular octahedron, which is its fundamental form; it usually, however, presents itself in large lamelliform masses, with distinct octahedral cleavages, in granular concretions, or compact. It is brittle, has the hardness of feldspar, and a specific gravity of 5.094. It exerts a decided action on the magnetic needle; and certain specimens, especially of a compact variety, attract and repel, alternately, the poles of a needle, according as we present the same point of a fragment of the ore to one or the other of the extremities of a needle. This variety, which is found in several countries, is called *native loadstone*. Its magnetic virtue strengthens by exposure to the air. The magnetic iron consists of 28.14 protoxide of iron, and 71.86 of peroxide of iron. It is infusible before the blowpipe, but assumes a brown colour, and loses its attractive power, after having been exposed to a great heat. It is soluble in nitric acid, and may be obtained crystallized by fusing it, as often happens in

the roasting of it, in furnaces, to effect its reduction. It occurs in primitive rocks, chiefly in gneiss, mica-slate, hornblende-slate, and chlorite slate, and rarely in limestone, when it forms veins, beds, or even entire mountains. It also composes the chief ingredient of certain sands, which have been washed and deposited by the same currents which separated it from its original beds. The different varieties of this ore are exceedingly rich in metal, often yielding eighty per cent. of iron, and are every where explored, when found in sufficient quantities, and connected with abundance of fuel and facility of transportation. In Sweden, it forms the object of numerous important explorations, among which may be cited that of the mountain of Taberg, near Jonkoping, in Smoland, where it is so abundant as to be worked under the open sky; that of the island of Utö, where excavations extend to a great distance under the contiguous sea; that of Dannemora, in Upland, which is at present under the control of the British; that of Gallivara, beyond the polar circle, where the ore forms an entire mountain; and, finally, those immense deposits of ferruginous sand which are so extensively wrought in Dalecarlia, in Smoland, and in Wermeland. The oxydulated iron is also explored at several places in Siberia, Piedmont, and the kingdom of Naples. In the United States, it exists in the greatest abundance, and is wrought at numerous localities. The primitive range of mountains upon the western side of lake Champlain, affords numerous veins and beds of it, sometimes more than twenty feet in thickness, and little intermingled with foreign substances. The principal works for its reduction are at Peru, and near Crown Point. A valuable deposit of the compact magnetic iron, precisely similar to that worked at Dannemora in Sweden, occurs at Franconia in New Hampshire, and is worked extensively at Munroe, Hamburg, and many other places. The present ore forms the best iron which is made for the manufacture of steel; and hence the employment of Swedish iron by the English for this purpose.

3. *Chromated Oxide of Iron (Chromate of Iron)* is found crystallized in regular octahedra, and massive. Lustre, imperfectly metallic; colour, between iron-black and brownish-black; streak, brown; opaque, brittle; hardness, the same with the preceding species; specific gravity, 4.498. Vauquelin and Klaproth make it consist of

Oxide of chrome, . . . . .	43.00 . .	55.50
Protoxide of iron, . . . . .	34.70 . .	33.00
Alumina, . . . . .	20.30 . .	6.00
Silica, . . . . .	2.00 . .	2.00

Alone, before the blowpipe, it is infusible, but acts upon the magnetic needle, after having been exposed to the reducing flame. It is dissolved when heated with borax, to which it imparts a beautiful green colour. It was first found in the department Du Var, in France, in the form of nodules and kidney-shaped masses. It was afterwards discovered in Stiria and Scotland; at the former place, imbedded in serpentine, at the latter, in limestone. In the United States, it exists abundantly in Maryland, near Baltimore; also, in small quantities, in Connecticut, near New Haven, in limestone, with serpentine. It is a highly valuable mineral, when it occurs in quantity, for extracting the oxide of chrome, which is employed either alone or in various combinations with the oxides of other metals, as cobalt, lead, mercury, &c., both for painting on porcelain, and for painting in oil. The quantity of chromate of lead, or chrome yellow, manufactured in Baltimore annually, is estimated at 50,000 pounds. See *Chrome*.

4. *Specular Iron Ore, and Red Iron Ore*. This species, scarcely less interesting than the last in economical importance, presents many difficulties to the

mineralogist, in consequence of the complicated forms of its crystals, and the diversified appearance of its compound varieties. It is crystallised in a great number of forms, whose fundamental figure is a slightly acute rhomboid of  $86^{\circ} 10'$  and  $93^{\circ} 50'$ , which may be derived from its crystals by cleavage. The general tendency of its secondary forms is to hexagonal prisms and irregular octahedra. Lustre, metallic; colour, dark steel-gray, iron-black; streak, cherry-red, or reddish brown; surface of the crystals frequently tarnished; opaque, except in very thin laminae, which are faintly translucent, and show a deep blood red colour; brittle; hardness, the same with the preceding species; specific gravity, 5.251. Its action upon the magnet is feeble; it never attracts iron filings, or offers magnetic polarity. Besides occurring in distinct crystals, and in lamelliform and compact masses, with a metallic lustre, it also presents itself in reniform, botryoidal, and stalactitic shapes, and earthy-looking masses, where, from the smallness of the individuals, no signs of the metallic appearance are discernible. These varieties have received distinct names, and have often been treated of, in mineralogical systems, as belonging to a distinct species, which, on account of their colour, has been designated *red iron ore*. But this distinction is now given up, as an uninterrupted transition has been noticed between all the varieties of the red iron ore and the crystalline specular iron. The following are some of the varieties of the present species, according as they have acquired distinct appellations in mineralogical books, and among mankind in general: that in distinct crystals is called *specular iron*; that in thin, lamellar concretions, with a metallic lustre, is called *micaceous iron*; the rest, with a metallic lustre, is denominated *common specular iron*. Those varieties which have lost their metallic appearance, are included within, 1, the red iron ore, divided into *fibrous red iron ore*, or *red hematite*; *compact and ochrey red iron ore*, which are massive, and consist of impalpable granular individuals, more or less firmly connected; and *scaly red iron ore*, or *red iron froth*, consisting of very small, scaly, lamellar particles, which, in most cases are but slightly coherent: 2. clay iron ore, divided into *reddle*, which possesses an earthy, coarse, slaty fracture, and is used as a drawing material; *jaspers*, clay iron ore, which has a large, flat, conchoidal fracture, and considerable hardness when compared with the other varieties of red iron ore; and *columnar and lenticular clay iron ore*, which are distinguished, the first by the columnar form, the latter by the flat-tish, granular form of its particles. The micaceous iron, analysed by Bucholz, and the red hematite, analysed by D'Aubuisson, have been found to consist of

Peroxide of iron, . . .	100.00	90.00	94.00
Oxide of manganese, . . .	0.00	a trace	a trace
Silica, . . .	0.00	2.00	2.00
Lime, . . .	0.00	a trace	1.00
Water, . . .	0.00	2.00	3.00

The proportion of metal to that of oxygen, in the species, is as 69.34 : 30.66. The clay iron ores, being more or less mixed with earthy substances, vary in their contents, and several of their properties are dependant upon the nature of these admixtures. The specular iron is infusible before the blowpipe, but melts with borax, and forms a green or yellow glass, like pure oxide of iron. It is likewise soluble in heated muriatic acid. The specular iron (in the crystalline, lamelliform, and compact varieties, with a metallic lustre) forms very powerful beds, and even entire mountains, which are traversed by a multitude of fissures, and cavities lined with small, but exceedingly brilliant crystals of this substance. It yields,

in the ordinary operations of reduction, sixty per cent. of metal. Its most celebrated locality is the island of Elbe, which has afforded iron for sixteen centuries. Its mines are still believed to be inexhaustible. They annually yield 32,000,000 of French quintals of ore, which are transported for reduction into Tuscany, the Roman states, Liguria, and the kingdom of Naples. It is also found at Framont in the Vosges (where its exploration occupies 200 miners), in Saxony, Bohemia, Sweden, Siberia, and in the United States of America. Wherever it exists, it is explored with profit. It deserves to be mentioned, also, that specular iron, in exceedingly brilliant crystals and scales, occurs very frequently among the ejected matter of volcanoes, as in the lavas of Vesuvius and Auvergne, where it is, undoubtedly, a product of sublimation. The red hematite is found in beds and veins, in primitive and secondary countries. It occurs abundantly in Saxony, the Harz, Silesia, and in England. It affords excellent iron, and often in the large proportion of sixty per cent. Most of the plate iron and iron wire of England are made of it. In Scotland, it is used, along with the ore of that country, at the Carron and Glasgow works. The ochrey red iron ore usually accompanies the other varieties of this species, and is treated conjointly with them. In places where it is found in considerable quantities, it is sometimes collected, washed, and employed as a polishing substance. The compact red iron ore is found in France and some other European countries, where it is reduced, and affords a good soft iron, yielding fifty per cent. of metal. But its most important use is as a polisher. It forms, when perfectly compact, the burnisher of the button-maker, by means of which he imparts to gilded buttons the highest polish of which they are capable. The best specimens for button-polishers command a very high price, and usually come from little pebbles and rolled masses of this ore, found in secondary countries. The following table exhibits a mineralogical analysis of nine specimens of iron ore found in the district of Clydesdale.

(a) From Crossbasket, about seven miles south-west from Glasgow. Colour light grayish, or greenish-black. Fracture from fine-grained even to coarse-grained, uneven, very easily frangible, soft, easily scratched by the knife. Specific gravity taken in distilled water at the temperature of  $69^{\circ}$  - 3.1720.

This is the highest and also the least valuable of the Crossbasket strata of ironstone, which are at present raised for the use of the blast furnace. The thickness of the stratum is from three to three and a half inches.

(b) From Crossbasket. Colour light grayish-black. Fracture fine-grained, earthy, slightly uneven. Rather tough, but particularly soft. Specific gravity 3.3001.

This ore is found at a distance of four feet under the ground in one. It constitutes a stratum of about nine inches in thickness, and is esteemed the purest and most valuable of the Crossbasket ores.

(c) From Crossbasket. Colour light grayish-black. Fracture fine-grained, earthy, slightly uneven. Rather tough, but more easily frangible, and softer than the last-mentioned ore. Specific gravity 3.2295. The average thickness of the stratum is from six to eight inches.

(d) From Crossbasket. Colour brownish-black. Fracture earthy, fine-grained, uneven. Easily frangible and soft. Specific gravity 3.1175.

This stratum of ironstone is situated next under that from which the preceding specimen was taken, and forms the lower

which is at present wrought at Crossbasket. It varies in thickness from ten to fourteen inches. Both it and the preceding are reckoned of good average quality. This ore furnishes a curious instance of the superfluous and seemingly unaccountable alterations that are liable to take place in every chemical manufacture, whose fundamental principles are little understood, and in some, perhaps, does this happen more frequently than in the smelting of iron. Although it forms the thickest of all the Crossbasket strata, and therefore holds out powerful inducements, in an economical point of view, to the iron smelter, it was at one period regarded at the Clyde iron-works as an ironstone totally unfit for the manufacture of good iron; and having once received an unfavourable character, it was allowed to remain unworked for a long course of years. It is only of late that its employment has been again resumed; but, so far from being held in low estimation, it is now considered to be little inferior in quality to any of the Crossbasket ores, and is used very extensively in the blast furnace.

Immediately above this stratum there is situated a bed of schist, containing a regular stratification of very large nodules of ironstone. Being extracted by the miner simultaneously with the subjacent ore, they are used to a considerable extent in the blast furnace, and are esteemed an ironstone of uncommon quality. The black bituminous substance which occurs sporadically in nodular ironstone, exists very generally distributed throughout this stratification of balls.

(e) A specimen found in the neighbourhood of Clyde iron-works, which are situated about four miles south-east from Glasgow. Its mineralogical details are the following:—Colour pale, between brocoli-brown and clove-brown. Fracture rather fine-grained, uneven. Not particularly hard, easily scratched by the knife. Specific gravity 3.1482. The thickness of the stratum is about two inches and a half. It is considered at the works to be an ore of a very inferior quality, and is seldom smelted.

Immediately above this ore there is situated a bed of schist, which contains an immense number of petrifications of different kinds of bivalve shells: they consist of a *very pure ironstone*, resembling in appearance the subjacent land.

(f) Their forms are remarkably perfect, and they contain no visible remains of the original shell.

(g) As ore lying under the last mentioned stratum, and in close contact with it. Colour between yellowish-grey and hair-brown. Fracture fine-grained, earthy, even. Rather hard; scratched with some difficulty by the knife. Specific gravity 3.2100. The stratum to which it belongs is situated above the splint coal, with the intervention of only four inches of schist, and both minerals are therefore worked out together with great advantage to the smelter. It is the most valuable ore in all the beds around Glasgow, except that called the *black ironstone*, which is at present smelted at the Clyde iron-works. The thickness of the stratum is between one and a half and two inches.

(h) This specimen was procured from Easterhouse, near the line of the Monkland canal, and about six miles east from Glasgow. Colour clove-brown. Fracture fine-grained, rather uneven. Somewhat tough and hard, but easily scratched by the knife. Specific gravity 3.3109.

This ore exists in precisely the same relative situation, with regard to all the other accompanying minerals, as the two ores from the Clyde iron-works, which have just been described; and wherever it makes its appearance, it seems to have been produced by the concurrence of these two strata. This compound stratum has always a uniform texture and composition throughout. Its average thickness is two and a half to three inches. It is used pretty extensively in the blast furnace, and is esteemed an ore of good average quality.

(i) From the neighbourhood of Airdrie, about ten miles east from Glasgow. Colour clove-brown, the intensity of the shade varying considerably in streaks which are parallel to the direction of the stratum. When reduced to powder the colour is brown. Fracture fine-grained, earthy, rather uneven. Tough, and difficultly powdered; communicating a feeling of elasticity under the pottle. Rather hard; scratched by the knife. Adheres slightly to the tongue, a property which did not appear to be possessed in a sensible degree by any of the ores already described. Specific gravity 3.0553. Numerous bivalve shells, of a pale wood-brown colour, occur scattered through the mass of the ore, and form a strong contrast with its darker shade. This is one of the most valuable iron ores of Scotland, where it is familiarly known under the name of *black ironstone* or *Musket's black sand*. The latter appellation has been given from the circumstance that it was first smelted by Mr Musket, to whom we have already referred as the metallurgist most distinguished for his practical skill.

It lies about fourteen fathoms below the fifth Glasgow coal-bed, or splint coal, and constitutes a layer about fourteen inches in thickness. It is remarkable that it has hitherto been found nowhere except in the neighbourhood of Airdrie; although several attempts have been made in other localities to reach it by boring. At the Clyde iron-works, it is justly regarded as the richest and most valuable ore which they at present possess.

(j) From a stratum situated in the vicinity of Crossbasket. Colour bluish-grey. Fracture, in the great, even; in the small, very fine-grained, earthy; rather hard.

The foregoing table and remarks are taken from Dr Colquhoun's paper, in Brewster's Edinburgh Journal for 1827-8.

5. *Hydrous Oxide of Iron, and Broken Iron Ore.* The present is a species nearly parallel to the foregoing, in the quantity of iron it affords to society.

It is very rarely observed in distinct crystals, more usually occurring in botryoidal and stalactical masses, consisting of closely aggregated fibres, in which respect it resembles the most common varieties of the specular iron. The crystals are very small, externally black and brilliant, and in the shape of right rectangular prisms. The general character of the species is as follows: lustre, adamantine; colour, various shades of brown, of which yellowish-brown, hair-brown, clove-brown, and blackish-brown are the most common; streak, yellowish-brown; brittle; no action on the magnet; scratched by feldspar; specific gravity, 3.922. Besides occurring in crystals, and in globular stalactitic and fruticose shapes, it is found in masses whose composition is impalpable; sometimes also, the particles are so slightly coherent, that the mass appears earthy and dull. It differs, chemically, from the specular iron, in containing a quantity of water, not merely interspersed through its substance by simple absorption, but intimately combined with it by chemical affinity. According to D'Aubuisson, it consists of (in two analyses)

Peroxide of iron, . . . . .	82.00	84.00
Water, . . . . .	14.00	11.00
Oxide of manganese, . . . . .	2.00	2.00
Silica, . . . . .	1.00	2.00

the proportion of peroxide of iron and water being as 85.30 to 14.70. Before the blowpipe, it becomes black and magnetic. It melts, with borax, into a green or yellow glass, and is soluble in heated nitromuriatic acid. The division introduced among the varieties of the present species, is somewhat similar to that which has been given to red iron ore. *Crystallized hydrous oxide of iron* embraces the small black crystals, which sometimes occur in fibrous and radiating bundles. *Crystallized brown iron ore* is that variety which presents itself in the form of the cube, rhomboid, or some modification of these forms, and does not properly belong to this species, being decomposed varieties of iron pyrites and spathic iron, to which they are more correctly referred. The *fibrous brown iron ore*, or *brown hematite*, contains the fibrous varieties, in stalactitic, reniform, and other imitative shapes. *Compact brown iron ore* comprehends those imitative shapes and massive varieties, in which the composition or fibrous structure is no longer observable; while *ochrey brown iron ore*, or *bog iron ore*, is applied to those which have an earthy texture and are friable. As impure varieties of the species, we must consider some of the clay iron ores, such as the *granular*, the *common*, the *pisiform*, and the *reniform* clay iron ore. The granular variety is composed of compact, roundish, or globular masses; the reniform one, of alternating coats, of different colour and consistency, disposed in a reniform surface. In the pisiform variety, we meet with a similar composition, only in small globules, parallel to the surface of which the lamellæ are disposed. The compact pisiform clay iron ore, however, does not belong to the present species, but it is decomposed iron pyrites, as is demonstrated, not only by the crystalline forms which it affects, but likewise from the nucleus of the undecomposed pyrites, which the largest specimens of it often embrace. The crystallized hydrous oxide of iron is found, in limited quantities, in England, France, and Siberia; it either occurs in quartzose geodes, in the form of mamillary masses, or is enclosed in quartz crystals. The fibrous brown iron ore is the most abundant and widely dispersed of all the varieties of this species. It is commonly found in large beds, in gneiss or mica-slate, and very frequently in immediate connexion with granular limestone. It is also found in Saxony and Thuringia, in beds and veins, embraced, in some instances, in newer rocks. It is uncommon in the northern countries of Europe;

but in Germany, France, and the Austrian dominions, it is wrought in great abundance. Its most remarkable deposit in the United States, is at Salisbury in Conn., where it has been wrought for nearly 100 years; the amount of pig iron yielded annually, at present, is about 2000 tons. The iron which this variety affords is superior in malleability to that yielded by the red ore of iron, and is much esteemed, also, on account of its toughness and hardness. The pig iron obtained from melting its purer varieties with charcoal, in particular, may be easily converted into steel. The compact variety of this species is usually found in the same localities with the fibrous hematite, and is equally employed with that variety for obtaining iron. The ochrey brown iron ore, or bog iron ore, is the most recent in its formation of all the ores of iron, its deposition being continually going on, even now, in shallow lakes and in morasses. It is wrought in all countries, more or less extensively; but the iron it yields is chiefly used for castings. The pisiform clay iron stone occurs imbedded in secondary limestone, in large deposits, in France and Switzerland, where it supplies considerable iron works; but the iron, like that from the other earthy varieties of the present species, is generally too brittle to be wrought into bar-iron.

6. *Arsenical Iron*, or *Mispickel*, is found crystallized in right rhombic prisms of  $111^{\circ} 12'$  and  $68^{\circ} 48'$ . These are often terminated by dihedral summits, and liable to a large number of modifications. It also occurs massive. Lustre, metallic; colour, silver-white, inclining to steel-gray; streak, dark grayish-black; brittle; hardness, nearly that of feldspar; specific gravity, 6.127. Its chemical composition is, iron 33.5, arsenic 46.5, and sulphur 20. Before the blowpipe, upon charcoal, it emits copious arsenical fumes, and melts into a globule, which is nearly pure sulphuret of iron. It is soluble in nitric acid, with the exception of a whitish residue. It sometimes contains a small proportion of silver; when it is denominated *argentiferous arsenical pyrites*. Arsenical iron is a pretty abundant substance, and occurs both in beds and veins, often accompanied by ores of silver, lead, and zinc. It is very plentiful in the mining districts of Saxony, in the silver mines of Joachimsthal, and the tin mines of Schlaggenwald, the Harz, Sweden, Cornwall, the United States, &c. The accidental admixture of silver renders some varieties of the present species useful as ores of that metal. The common arsenical pyrites, when occurring in large quantities, is employed in the manufacture of white arsenic and of realgar.

7. *Axotomous Arsenical Pyrites*; a species differing from the preceding in the inclination of the lateral faces, which, in the present case, meet under angles of  $122^{\circ} 26'$  and  $57^{\circ} 34'$ , and in specific gravity, which in this species is 7.228. It has not yet been analyzed, but is believed to consist wholly of iron and arsenic. It has been found in beds, in primitive mountains, in Carinthia, Silesia, and Stiria.

8. *Iron Pyrites* is the most universally distributed of all the ores of iron, and, from its yellow colour and metallic aspect, is the substance which is so frequently mistaken, by ignorant people, for gold. It is not uncommon to find it regularly crystallized, though the dimensions of the crystals are rarely such as to render them very conspicuous. The prevailing figure among its crystals is the cube, parallel to whose faces they may be cleaved, as also parallel to the sides of the regular octahedron. The last is assumed as the primitive form of the species by most mineralogists, as leading to an explanation of the numerous secondary forms with the greatest simplicity. The most frequent of these secondaries are the cubo-octahedron, the pentagonal dodecahedron, and the josi-

tetrahedron. The surfaces of the crystals are sometimes smooth, and sometimes alternately striated. Fracture, conchoidal, uneven; lustre, metallic; colour, passing through a few shades of a characteristic bronze yellow; streak, brownish-black; brittle; hardness, such as to be impressed with the knife, and scratched by feldspar; specific gravity, 4.98. The crystals are liable to be much grouped, often penetrating each other so as to form globular masses. It occurs, also, in granular, columnar, and impalpable masses; and often cellular, in consequence of forming upon crystals of galena, which have subsequently become decomposed. Iron pyrites consists of iron 45.74 and sulphur 54.26. In the exterior flame of the blowpipe, it becomes red upon charcoal, the sulphur is driven off, and oxide of iron remains. In heated nitric acid, it is partly soluble, and leaves a whitish residue. Some varieties are subject to decomposition, when exposed to the action of the atmosphere. With regard to its geological relations, much diversity obtains; it constitutes beds by itself of considerable magnitude, in gneiss, mica-slate, and primitive argillite, and is often an important ingredient of those beds which contain ores of lead, iron, copper, &c. It is frequently mixed with coal seams and the beds of clay which accompany them. It is also met with, in considerable quantities, in veins, associated with blende, arsenical iron, galena, and copper pyrites. It is found, likewise, with ores of silver, and is contained in many organic remains, both of vegetable and animal origin. Its localities are too numerous to admit of being noticed with particularity. Some of the most beautiful crystallizations which adorn mineralogical cabinets, are brought from the island of Elba, Piedmont, Saxony, Harz, Norway, and Cornwall. Vast deposits of iron pyrites, intermingled, in some instances, with magnetic iron pyrites, are found in the United States, and also abound in the gold region of the Southern States, being wrought extensively in many places for the sake of the gold mechanically mixed with it, from the presence of which it receives a golden-yellow tinge. The uses of this species are as follows: it is roasted for extracting sulphur; after having been exposed to the oxidizing influence of the atmosphere, it yields sulphate of iron, or copperas, and sulphuric acid; the remaining oxide of iron is used as a coarse pigment; it is an important agent in several metallurgical operations, and was formerly considerably employed instead of flints in gunlocks, from whence the name *pyrites* was derived.

9. *White Iron Pyrites* differs from the preceding species in its crystalline characters, as well as in some other respects, though, in chemical constitution, the two appear to be perfectly identical. Its crystals are in the form of modified rhombic prisms, and of very flat crystals, having the appearance, at first sight, of dodecahedrons with triangular planes, but which, however, are macles, consisting of similar portions of five crystals. The primary form is a right rhombic prism, of about  $100^{\circ}$  and  $73^{\circ}$ , parallel to the planes of which it yields to mechanical division. The faces of the crystals are deeply striated, in a vertical direction. Lustre, metallic; colour, pale bronze-yellow, inclining to gray; streak, grayish-black; hardness, equal to that of feldspar; specific gravity, 4.67. It occurs massive, and in various imitative shapes, in consequence of which, and the composition of its crystals, it has been distinguished into several varieties, as *radiated pyrites*, *spiral pyrites*, *cock's comb pyrites*, *hepatic pyrites*, and *cellular pyrites*. Before the blowpipe, it behaves like common iron pyrites. Some of its varieties are peculiarly subject to decomposition. It is less frequently met with in nature than the preceding species, though very often found accompanying it. It occurs

more frequently in rocks of the coal formation, and in strata of clay. Its principal localities are in France, Bohemia, and Hessa. It is useful for the manufacture of sulphur, sulphuric acid, and cop-pers.

10. *Magnetic Iron pyrites* is rarely seen in well formed crystals. Count Bourmon describes it as occurring in irregular six-sided prisms. In general, it is massive and foliated, or fine granular. Lustre, metallic; colour, intermediate between bronze-yellow and copper-red; streak, dark grayish-black; subject to tarnish; slight action on the magnet; brittle; hardness, considerably inferior to that of common iron pyrites, or that of white iron pyrites; specific gravity, 4.63. It consists of iron 62.77, and sulphur 37.23. It occurs in beds, along with other minerals, usually in primitive rocks. It exists plentifully at Bodenmais, in Bavaria, and several districts of Stiria. In the United States of America, it occurs in quartz, along with blende, galena, tungsten, and along with iron pyrites. Its uses are the same as have been mentioned in connexion with the other species of iron pyrites.

11. *Phosphate of Iron, or Vivianite*, occurs crystallized, in the form of a right oblique-angled prism of  $125^{\circ} 18'$  and  $54^{\circ} 42'$ , which is that of the primary crystal. The crystals are long and slender for the most part, though generally very small. They are attached to their gangue by one of their broad lateral planes, or occur in aggregated groups. Lustre, pearly, approaching to metallic on certain faces; on others, vitreous; colour, pale blackish-green; sometimes approaching indigo-blue; streak, bluish-white; the powder produced by crushing the mineral in a dry state is liver-brown; translucent, and rarely transparent; sectile; thin laminae are flexible; specific gravity, 2.66. It also occurs massive, in small, reniform and globular shapes, and imbedded nodules; also in superficial coatings of dusty particles. The earthy varieties are dull, opaque, meagre to the touch, and light. Their colour, on first exposure to the light, is grayish, yellowish, or greenish-white, or some pale tinge of blue; but it soon passes to a dark indigo-blue. In two varieties of vivianite (a friable one analyzed by Klaproth, and a crystallized one from Bodenmais in Bavaria, by Vogel), the following chemical composition was discovered:—

Protoxide of iron, . . . . .	47.50	. . .	41.00
Phosphoric acid, . . . . .	32.00	. . .	26.40
Water, . . . . .	20.00	. . .	31.00

It decrepitates before the blowpipe, but melts, if first reduced to powder, into a dark-brown or black scoria, which moves the magnetic needle. It is soluble in dilute sulphuric and nitric acids. It occurs in a variety of geological situations. The crystals are found in copper and tin veins, and sometimes in greywacke accompanying native gold; also in basalt and trap rocks. The earthy and massive varieties are imbedded in clay, and often accompany bog iron ore. The crystalline varieties come from Cornwall and Bavaria; the foliated and earthy varieties abound (especially the former) in the United States of America. It is confined to argillaceous and ferruginous deposits, and is sometimes found in connexion with bones, and very usually filling up the casts of belemnites and other fossils. The earthy vivianite is sometimes employed as a pigment.

12. *Arseniate of iron* occurs in small cubic crystals, which are either unmodified, or have their alternate angles or their edges truncated. Lustre, adamantine, not very distinct; colour, olive-green, passing into yellowish-brown, bordering sometimes upon hyacinth-red and blackish-brown, also into grass-green and emerald-green; streak, similar to the colours; translucent on the edges; rather sectile; scratched by

fluor; specific gravity, 3.00. According to two analyses, it consists of

Oxide of iron, . . . . .	45.50	. . .	48.00
Arsenic, . . . . .	31.00	. . .	18.00
Oxide of copper, . . . . .	9.00	. . .	0.00
Silica, . . . . .	4.00	. . .	0.00
Carbonate of lime, . . . . .	0.00	. . .	2.00
Water . . . . .	10.50	. . .	32.00

Exposed to a gentle heat, its colour is changed into red. In a higher degree of temperature, it intumesces, gives little or no arsenic, and leaves a red powder. Upon charcoal, it emits copious fumes of arsenic, and melts in the inner flame, into a metallic scoria, which acts upon the magnetic needle. It principally occurs in veins of copper ores, traversing the older rocks, and its chief localities are Cornwall and Saxony.

13. *Carbonate of Iron, or Spathic Iron Ore*, occurs crystalline and massive. Its crystals are acute rhomboids, sometimes perfect, or only having the terminal angles replaced, six-sided prisms, and lenticular crystals. They are very easily cleavable, yielding obtuse rhomboids of  $107^{\circ}$  and  $73^{\circ}$ . Lustre, vitreous, inclining to pearly; colour, various shades of yellowish-gray, passing into ash and greenish-gray, also into several kinds of yellow, white and red; streak, white; translucent in different degrees; brittle; hardness, nearly identical with that of fluor; specific gravity, 3.829. It occurs massive, in broad, foliated and granular masses; also in fibrous botryoidal shapes, whence it has received the name of *sphaeroiderite*. Two varieties of this species, 1. the *sphaeroiderite*, and 2. a cleavable variety from Newford in the Harz, have yielded to Klaproth, (1.) (2.)

Protoxide of iron, . . . . .	63.75	. . .	47.50
Carbonic acid, . . . . .	34.00	. . .	36.00
Oxide of manganese, . . . . .	0.75	. . .	3.30
Lime, . . . . .	0.00	. . .	1.25
Magnesia, . . . . .	0.52	. . .	0.00

Before the blowpipe, it becomes black, and acts upon the magnetic needle, but does not melt. It colours glass of borax green. It is soluble with difficulty in nitric acid, particularly if not reduced to powder. On being exposed to the air, it is gradually decomposed: first the colour of the surface becomes brown or black; afterwards, also, the streak is changed into red or brown; hardness and specific gravity are diminished; and even the chemical constitution is altered, the whole being converted into hydrate of iron. It frequently occurs, along with carbonate of lime, in veins and beds, in primitive rocks; also in metalliferous veins, accompanied by galena, gray copper ore, and iron and copper pyrites. Immense beds of it exist in Stiria and Carinthia, as well as in France, Switzerland, and Siberia. In the United States of America, there is a vein of it at New Milford in Connecticut, crossing, with the breadth of six feet, an entire mountain. In France, Stiria, and Carinthia, large quantities of cast and wrought iron are obtained from the sparry iron ore, but particularly steel, for the production of which it is highly valuable.

14. *Oxalate of Iron, or Humboldtine* is an ore of iron found near Berlin, in Bohemia, in a moor-coal, or friable lignite. It consists of protoxide of iron 53.56, and oxalic acid 46.14. It is supposed to owe its origin to the decomposition of succulent plants. It occurs in small flattish masses, of a light yellow colour; is soft, yielding to the nail, and of the specific gravity of 1.3. By rubbing, it acquires resinous electricity. It decomposes easily on live coals, giving out a vegetable odour. It is insoluble in boiling water and alcohol.

15. *Sulphate of Iron or Copperas*. This salt is not frequently found in nature, in distinct crystals, but usually occurs in stalactitic, botryoidal and reniform masses, and occasionally pulverulent. The

crystals are in the form of right oblique-angled prisms, considerably modified by replacements; fracture, conchoidal; lustre, vitreous; colour, several shades of green passing into white; streak, white; semitransparent and translucent; brittle; hardness, that of gypsum; specific gravity, 1.83; taste, sweetish-astringent and metallic. It consists of

Oxide of iron, . . . . .	25.7
Sulphuric acid, . . . . .	28.9
Water, . . . . .	45.4

It is easily soluble in water, and the solution becomes black on being mixed with tincture of galls. If exposed to the open air, it soon becomes covered with a yellow powder, which is persulphate of iron. Before the blowpipe, it becomes magnetic, and colours glass of borax green. In most instances, it is produced by the decomposition of other minerals, particularly of iron pyrites and magnetic iron pyrites; and the crystallised varieties are rarely found, except in those places where artificial heaps of these substances have been formed. It is also found incrusting slate rocks, and dissolved in the waters of certain mines.

*Treatment of the Ores.*—Of the fifteen species of iron ore just described, but four are employed for obtaining metallic iron and steel, viz., magnetic iron ore, specular iron ore, brown iron ore, and carbonate of iron. The metallurgical details belonging to the treatment of these ores, cannot be described within the limits of the present work.

When the iron stone lies in a stratum or vein between two strata of clay, not more than thirty feet below the surface of the earth, it is obtained by sinking a pit, at first, of a diameter of eight feet, and deepened until the ore is reached where the pit is undermined, until the diameter at the bottom becomes twice that at the top. When all the ore is taken out of this pit, another is dug similar to the first, and near it; so that when the second pit is excavated, the bottom of the two will meet. In digging the second pit the earth is thrown into the first, and thus one pit is made and another filled, until the whole vein is exhausted. When the iron stone lies deeper it is extracted in the same way as coal, and as they frequently occur in the same district, one engine serves to drain and draw for both ore and coal.

The first step after the ore has been taken from the vein, is to calcine the stones; a process technically called *roasting*. This consists in the application of a moderate heat, whereby the more volatile components of the ore, such as sulphur, arsenic, &c. are expelled. This is effected by spreading upon the ground a stratum of coals to a depth of about eight inches, ten feet long, and eight broad; over which is laid a layer of iron stone, to a depth of about six feet, interspersed with small cinders and coke dust, and covered with small coals. The coals being set fire to, combustion will go on for nearly a month, when the cementation is completed. It is not uncommon to perform the roasting process in a kiln, the coal and iron stone being put in at the top, and the roasted ore taken out at the bottom. Care is requisite in conducting the process of roasting, for if the heat be too intense, or too long applied, then will the metal partially melt and the pieces cake together, and if on the other hand the heat be too little, all the extraneous matter, such as the water, sulphur, &c., will not be expelled, when the iron stones must be thrown aside, as unfit for the future processes in the manufacture. The iron stone of this country usually contains a sufficiency of carbonaceous matter to carry on the roasting after the fuel has been ignited; but the ores of the continent contain less carbon, and therefore require proportionally more fuel for their

cementation. On the continent and in America, iron ore is most commonly roasted with wood and charcoal. When the roasting is performed with charcoal alone, a layer of the ore is laid on the ground, then a layer of charcoal, and so on alternately, the iron stone layers being each about nine inches, and the charcoal about six, until the height of the bed be seven feet. It is better, however, to lay a stratum of wood below the ironstone. When the roasting is completed, the ore becomes friable, rough to the touch, not at all vitreous, but full of fissures. The ore by the power of cementation, sustains a loss of weight of from twenty to fifty per cent.; according to the quality of the ore. The iron stones thus prepared are called by the workmen *mine*.

The next operation is the conversion of the roasted ore into metal, by the application of strong heat in a furnace; which process is called *smelting*. As will be readily understood after what we have said on the ores of iron, they commonly consist of an oxide of the metal combined with some earthy matter, in very various proportions. If these ores were fused alone, the chemical student will at once perceive, that they would be formed into glasses, the properties of which will vary with the composition of the ore, but retain no metallic character. The method of proceeding, therefore, must be to intermix the iron stones with such substances as during the process of fusion, will combine with the oxygen and earthy matter of the ore, and leave the metal free. From the great affinity of carbon for oxygen, forming carbonic acid gas, charcoal, or some other carbonaceous substance, is selected as the proper substance for separating the metallic base from the oxygen; and the nature of the other substances to be employed in separating the earthy matter of the ore, will be determined by the species to which that earthy matter belongs. The earths mixed with the iron, may be either calcareous, silicious, or aluminous: these exist in different proportions, in different ores, and it should be the first object of the iron manufacturer, to select such earthy matter as a flux, that when combined with the earthy matter of the iron stone, a glass will be formed, and the metallic base of the ore left free. Sometimes the combination of several kinds of ore, will produce a congeries of earths that of themselves will form an excellent flux—but this, in the ordinary course of manufacture, never occurs, so that some flux, such as lime, is always employed.

The strong affinity of carbon for oxygen, as before remarked, points it out as the best substance for separating the oxygen from the iron. In Russia and Sweden, and even in some parts of England, charcoal is employed, and it undoubtedly is best for making that kind of iron that is to be formed into steel. For many years past, almost the only ore in Britain that has been smelted with charcoal, has been the red ore of Lancashire, which being extremely rich, the product of smelting can be calculated upon with certainty. The abundance of coal in this country, in those districts where iron stone is found, determines our iron makers to employ coke from its cheapness; coal when properly coked, yields a very considerable proportion of carbonaceous matter, and bears a strong resemblance to charcoal. When coke was first introduced instead of charred wood, it was made, by merely piling the coals in a heap, which being ignited, were allowed to burn until sufficiently coked, when they were covered with ashes and mud to prevent any further combustion. In many places in Wales, this plan is still pursued. From thirty to forty tons of coals, are piled in a heap, as loose and open as possible. Small coals being spread on the surface to give a level appearance. It is then ignited

in various places, and allowed to burn till the whole surface is in combustion; when it is covered with the ashes of a former fire, and left to go out. The coke is made harder and more pure, when the cooling of the heap is quickened by throwing on cold water. A slight knowledge of chemistry is sufficient to show, that much of the coal must be converted into ashes before combustion can be carried a sufficient length to cask the heap, and the more economical process of coking in a close oven, or furnace, is now becoming more general. The ovens are of a hemispherical form, about ten feet wide at the base, and two feet at the aperture, the wall being of brick, eighteen inches in thickness. There is a door-way in the side, for the purpose of taking out the coke, and the opening at the top is for charging the oven with fresh coal. Small refuse coal is used. The oven being filled up to the springing of the arch, and the heat of the oven from the former coking being adequate to set the coal on fire, the door-way is filled up with loose bricks, and the air, rushing through the crevices, supports the combustion until the whole charge is lighted up, when the door way is plastered up, excepting the top row of bricks, and in twelve hours after covered entirely. The chimney remains open until the flame be extinguished, when it is closed, and the whole allowed to remain for twelve hours more, after which the coke is withdrawn from the doorway. The coke thus formed is of a grey colour, metallic lustre, and very hard; but when it is required to be of a nature more resembling charcoal, the coking is prepared in a place similar to a baker's oven, the door of which is kept constantly open, and the coals frequently stirred. Coke made in this way is black in colour, porous, and very light—more inflammable than the first description, but not capable of affording such intense heat, nor so durable in the smelting furnace.

The construction of the smelting furnace, will be understood, from the subjoined section.

Fig. 1.

The interior of the furnace, is a cavity, formed by the frusta of two cones joined at the base, and terminated in cylinders both at top and bottom, as will be seen at G, in the figure. The wall *ad* of this cavity, consists of the best fire brick, well cemented together, the thickness of the wall being generally fourteen inches. At a distance of about six inches behind this wall, a wall or casing of brick is built all round the former, and of a thickness of fourteen inches. The space between these two walls is filled up with river sand, crammed in compactly. Sand being but an indifferent conductor of heat prevents the casing *ab* from being much affected by the fire of the furnace. The whole is enclosed by the outer wall, A, of ashlar stone, or brick. This wall is built very strong and thick; the interior is of course made circular to envelope the casing *ab*, but the exterior face of the wall, is made to terminate in four faces, tapering to the top, so that the outward appearance

of the furnace, is a truncated quadrangular pyramid. The inside of the furnace, G, is made to terminate in a cylindrical chimney, and at the bottom, in a deep quadrangular pit H. Such is the construction of the furnaces erected in this country till of late, the whole building being made for substantiality as thick as possible. But the strong heat of the furnace, frequently so expanded the material, as to burst the mason work, and the modern furnaces are all constructed of comparatively thin walls above AA, nor is there any space left in them for the introduction of sand between the two interior walls of brick work. At the top of the chimney, there are formed two or more doors by which the workmen introduce the ore, coke and flux, and above this there is a semicircular wall E erected for the purpose of preventing the flame from blowing upon the workmen while they are feeding the furnace. The materials are drawn up on a mound of earth at the back of the furnace, either by machinery or by animal strength, and being set fire to at the bottom, are allowed to burn, the combustion being afterwards accelerated by a blast from a blowing machine. (See *blowing machine*). The ends of the pipes from the blowing machine enter nearly at the bottom of the furnace, as may be seen by inspection of figure 4. These blast pipes, the nozzles of which are technically called tweers, are two in number, and enter the furnace opposite to each other, and a little above that point where the melted metal rests. The ore, coke and flux, in the body of the furnace, are acted upon by the heat, just as they would be in a close vessel, the oxygen of the ore combining with the carbon of the coke, and forming carbonic acid, or rather carbonic oxide. On the ore parting with its oxygen, the carbon combines with the metal, and the mass being reduced, falls down to a lower part of the furnace, and in this way, makes room for more to come down to the hotter part, and in its turn be smelted, and the liquid metal to fall down to the bottom of the part H, called the hearth. It may be observed, that of late it is not usual to construct the hearth as deep in proportion as it is shown in the foregoing section.

There is an opening in the wall at the bottom of the hearth, at the mouth of which a stone is placed, called the *dam* stone, beyond which an opening is made in the side of the outer wall, in order to run off the liquid metal when it rises so high as to cause the scoria to flow over the dam. The opening in the outer wall is closed by a lute of sand mixed with clay, during the process of smelting; but when there has been a sufficient quantity of metal formed, the lute is removed, and the iron allowed to run off into a channel, made in a kind of sand. From this channel, called the *sow*, numerous side branches are led, called *pigs*, and as the melted metal flows along the sow, it is checked frequently by the workmen introducing a piece of wood which causes it to flow into the side channels, and thus the masses of iron called pig iron are formed.

The height of the smelting furnace is sometimes not less than sixty feet, but the usual height of the furnaces in this country, is about forty-five or fifty feet. The proportions of the parts may be guessed at, on inspecting figures 1. and 2. in this article. It may be stated in addition to the description already given, that there are numerous small openings through the sides of the walls, to permit the escape of the vapours and gases formed during the process, and to ensure durability, the whole of the mason work is bound with bars of iron. Dr Ure states, that a furnace of ordinary dimensions, will make about three and a half tons of cast iron, these furnaces being tapped once in twelve hours. For the production

of this quantity of metal, there is required seven tons of coke, eight tons of roasted iron stone, and three and three-eighths tons limestone as a flux. According to a later writer on the iron manufacture, one of the large furnaces in Wales receives on an average, fifty charges in twelve hours. Each charge requires six cwt. of roasted ore, in all amounting to fifteen tons produced from eighteen tons of raw mine. The same quantity of coke is required, i.e. fifteen tons produced from about twenty-two and a half cwt. of coals. The limestone required, is six tons, so that the whole weight of the charges for twelve hours, is thirty-six tons, from which only six tons of cast iron are produced. From this, we may estimate the loss of material in roasting, coking and smelting for two runs which occupies twenty-four hours.

Coals, . . . . .	57 tons.	
Mine, . . . . .	36	
Limestone, . . . . .	12	
Whole weight, . . . . .	105	
Supplied to the furnace, . . . . .	72, . . . . .	33 tons.
Iron produced . . . . .	12, . . . . .	60

Total loss, 93 tons.

In England and everywhere else until very recently, it was supposed, that the colder the air was injected into the furnace the better; and the two currents on entering the furnace chilled the materials much, and produced a sort of pipe or channel in the melted metal, which opposed its entrance. These pipes often extended so as nearly to meet in the middle of the furnace. The keeper watched the state of these pipes, and regulated the blast, so that they should neither be too long nor too short. These pipes tended to prevent the blast pipe, as well as the cast iron lining of the wall, through which they were led, from melting.

Mr J. B. Neilson, civil Engineer and manager of the Gas Works of Glasgow, had, in the course of the year 1824, directed his attention to blast furnaces, in consequence of some inquiries having been made, if he could devise any means of purifying the air propelled by the blowing engine before it reached the furnace; in any way similar to that in which coal gas is purified. The inquirer suspected that it was the presence of the sulphurous vapour, that injured the air of the blast, seeing that furnaces commonly wrought worst in the summer months. But experience led Mr Neilson to attribute the evil to another cause. From some simple experiments, he concluded, that by heating the air before it went into the furnace, he could effectually remove the evil under consideration. It is known that air will not support combustion until heated to a temperature of 1000° Fahrenheit, and therefore until it acquires that temperature, by coming into contact with the heated mass of the fire, it must act prejudicially: from which it is manifest, that the nearer it can be brought to that point before entering the fire, the better; yet all things considered, there may be a certain temperature at which the effect of the blast will be a maximum. The temperature originally employed by the patentee was, we believe, about 300° and this was the heat of the blast at Clyde iron works in 1830, when coke was employed. The advantage obtained by the employment of the hot blast at this temperature will at once appear from the fact, that during the first six months of the year 1829, when all the furnaces at Clyde iron works, were wrought with the cold blast, 8 tons 1½ cwt. of coal, converted into coke, were required for the smelting of one ton of cast iron, but during the first six months of 1830, when the blast was heated to about 300°, the same quantity of iron required only 5 tons ¾ cwt. of coals converted into coke, which after deducting 8 cwt. of

coal employed in heating the air gives a saving of 2 tons 10 cwt. The success of the hot blast, at a temperature of 300° induced the iron manufacturers to try it at a still higher temperature, and the results proved proportionally beneficial. In the course of the year 1831, the temperature of the blast was doubled, so that it was not less than 600°, and the success was such, that they were induced to employ coal instead of coke in the smelting furnace, which induced a saving to a very considerable amount. In 1829, 8 tons 1½ cwt. of coal were required for coke to smelt one ton of iron, whereas in 1833, only 2 tons 13½ cwt. of coals, not converted into coke, were required for the same purpose. The increase of combustion with the blast at 600°, precludes the necessity of coking before smelting, for the intense heat of the blast is sufficient to compensate for the great quantity of latent heat that must arise with the vapours expelled from the coals during combustion.

The patentee does not confine himself to any particular mode of heating the pipes, nor the temperature of the air. In some cases the pipes have been heated by the smelting furnace itself, and in others, by a separate furnace, which latter mode would appear to be the most economical.

We will here lay before the reader, a description of furnaces heated in both ways, which with some modifications, we have drawn up, from a very valuable French work entitled *Portefeuille Industriel*, (Jan. 1836), in the course of publication at Paris.

The annexed cut represents the first form of the air-heating apparatus, invented by Mr Neilson where a separate fire is used.

Fig. 2.

The heating apparatus is contained within a kiln or furnace, F F', constructed of brick. Within this kiln two straight tubes, A B A B, are laid horizontal and parallel to each other. In the upper surface of each of these large pipes, circular openings, C C' are made for the reception of the ends of small bent tubes. These tubes which are seen at S S' are bent so as to form arcs of circles, the length of each are being more than the circumference. They stretch across the kiln, one extremity terminating in each of the long pipes, A B A B.

Fig. 3.

There are four small tubes, *a b, a' b'*, fixed into the extremities of these long pipes, *A B, A' B'*, as may be seen more particularly in the ground plan, fig. 3. It is necessary to attend to the manner in which these pipes are fitted into each other, as the joinings must be made perfectly air-tight and strong. This is effected in the following manner:—The extremities of the great pipes, *A B, A' B'*, are formed into trutums of cones, the smaller parts of which are at the extremities, curbs being placed within at the bases. The little pipes are made to terminate in conical swellings, the base of each being at the very extremity, but of such a magnitude that it may be introduced into the end of the large pipe, and be pressed against the curb. The space between the conical end of the large pipe, and the swelling of the small one is filled with mastich, in which way the joint is firmly secured. The bent pipes, *D S D'*, are fixed in a similar way. The construction of the furnace is altogether analogous to the reverberatory kind, as will be seen by inspecting fig. 2. The walls are formed of common brick, but fire bricks are employed for the vault. In order to give sufficient strength to the building, the walls are bound by ten cast iron pillars, *F F*, bound together by beams, enclosed in the brickwork, as may be seen at fig. 2, and each end is likewise furnished with four similar supports. The fuel is thrown upon the grating *G*, through the door *H*, the air which supports the combustion entering from *K*, the ashpit below. The smoke from the fire proceeds up by the inclined back *I*, and rising strikes the bent pipes, which stretch across the vault. It will be easily seen that in this way the last of the bent pipes receive more heat from the smoke than the first, but this is compensated for by the form and position of the vault and the bottom, which cause much more of the heat to be radiated to the first tubes, both from the fire and from the vault. The flame and smoke having acted on the bent pipes, pass through the opening *L*, and from thence into the chimney. In order to save the joinings of the bended tubes, *D S D'*, with the large tubes, *A B, A' B'*, a wall of brick proceeds along the whole length of the furnace, on each side of the fire, and between that and each large pipe, built in such a way as to protect the joinings. The manner of operating is simply this:—The air from the blowing engine is propelled with the requisite force into the pipe *A' B'*, through the extremity, and passing through all the eight bent pipes *D S D'*, passes through the large pipe *A B*, through its extremity *b*, and by means of the connecting pipe into the furnace, where the smelting is effected. The pipes *D S D'*, being kept at a red heat, it must follow that the air must enter the smelting furnace, at a temperature very much higher than when it was propelled from the blowing engine.

The inventor has given the dimensions of an apparatus, such as we have described, calculated to supply a furnace with 800 cubic feet of air per minute. The dimensions of the horizontal pipes *A B A' B'*—

Length	Feet.
Exterior diameter	12.008
Interior do.	1.1808
	0.90

We will now describe the structure of the apparatus for heating the blast by means of the smelting furnace itself. The furnace is represented in section, in the wood engraving, below. This acts on

Fig. 4.

the same principle as that just described, the chief difference being in the manner in which the heat is obtained. The reverberatory furnace, with its system of horizontal and bended pipes, is placed on the top of the chimney of the smelting furnace, and the heated air and smoke from the large furnace enters the small furnace just where the grating was placed in the former construction. It may be remarked that the three first bended pipes are directly above the flues of the smelting furnace, and therefore receive the first action of the flame and smoke, which are reflected again by the vault, before entering the chimney, which is here made to rise directly from the end of the vault, instead of communicating by a horizontal pipe, as in the former construction. The distance of the large horizontal pipes is somewhat greater than the diameter of the flue *i. e.*, the chimney of the smelting furnace, in consequence of which the furnace is fed through the opening *N*. The communication between the heating apparatus and the blowing engine is similar to that formerly described, but the heated air passes out of the system of pipes at the top of the smelting furnaces, and is propelled into the tweers, which are seen entering at the bottom, through two pipes, which are led down the exterior wall of the furnace, as may be seen on inspection of the figure. The furnace we have just described, is better calculated for smelting by charcoal than by coke, as the heat raised by the former is much greater than by the latter.

In order to complete the description of the apparatus with hot air invented by Mr Neilson, it remains for us to describe the system of heating, which is employed in Wilkinson's foundry, in the cupolas intended to melt the metal. This application of Mr Neilson's invention is due to Mr Taylor. Various other applications of the hot air blast have been recently made by Schaeffelen, of Wurtemberg, who causes the air to pass through a sort of syphon in the chimney, before it reaches the grate.

K

This system of heating is represented in fig. 5 and 6. A A is the frame-work itself, which is constructed of common bricks, the interior being lined with fire bricks, in order to form the melting pot A', and the exterior of it is covered with sheet iron plates, A'', rivetted altogether, and bound with iron circles a'. The blast enters the cupola alternately by the different pipes a'; the lowest of them is used to commence the process, and as the height of the melting metal rises in the pot, they change them in order, so as always to blow at a suitable height to the bath of metal: the openings of the pipes which are not in use, are luted with care, especially when they

Fig. 6

have to support the pressure of the liquid contained in the melting pot. The tap hole is at a, it is always hermetically shut with a stopper, which may be lifted out in a moment from the tap hole.

The only modification that they have attempted to make, to improve the frame-work is in leading to the top, a slope by which the charges of coal and of pigs are thrown in; the opening is usually shut by the door b, which is lifted and attached by the little chain b', during the very short time which is necessary to throw in the charge.

There are three cast iron plates, placed one above another c, c', c'' of the same diameter as the frame-work, and pierced in the centre with circular holes a little greater than the diameter of the melting pot A'. The first c' has a little jutting out c'' (fig. 6), serving as a point of support to the fanner by which the furnace is supplied with the blast. The fanner is put in motion by means of a belt led over a drum on its axis, and connected with the steam engine, or water wheel. The second plate c, has a hole at the centre, a little greater than that of the

first, that it may be protected against the action of the heat. The third has a central hole, still a little greater for the same reason, but its exterior diameter is much less, so that it may leave upon the second plate c' an open circular ring of from twelve to fifteen inches. Upon this third plate c, there are fixed two concentric cylinders of plate iron D and D', which are open below, but shut above, and the tops of which are firmly joined by a sort of open joint d, d'. The exterior cylinder has two openings e and e'; one, that by which the cold air is introduced, the other, that by which the air goes out after being heated between the two coverings D and D'; at the distance of twelve or fifteen inches from the exterior envelop D, a third envelop F, of brickwork, is built, which is bound together with circles of iron, as the frame-work itself. The bottom of this last, rests upon the circular space, that the plate c lies open upon the plate iron c', and at its top it is shut by a convex iron plate f, upon which is erected a vault of some non-conducting substance. The iron plate is pierced in the middle with a hole, which is shut by means of a lid f', above which is put a steam stopple G; this order of things serves to inspect and to clean the interior of the apparatus, as it is only necessary to lift the stopple G and the lid f'.

Above this opening at the top, which remains always shut during the operation of melting, the envelop F is carried down the side to its lower part; there are two openings H H, into which are fixed the strong iron pipes I I, which serve as a base and support to the two chimneys K K; the pipes I, I are shut at their extremities by stopples i, i, which require only to be lifted out when they wish to sweep the chimney.

The smoke rises and spreads itself in the interior of the first envelop D', and after heating the sides, goes out from this space by the little conduit d d', then passes under the vault f, in order to descend between the exterior envelop F and the cylinder D, so that it may arrive at the two openings of the tubes I I, and at the chimneys K K.

The cold air enters by the opening e', between the envelops D and D', and it comes immediately into contact with the hot tops of these cylindrical coverings: it comes also into contact with the sides of the conduits d d', which are also at a very high temperature; thus heated against these surfaces, it descends in the spaces comprised between the envelops D and D', the one struck by the flame descending, the other by the flame ascending, and it arrives at the lower opening e, by which it escapes to the blast pipes. A the blast pipe ought successively to be raised, so as to be put into the different openings e e e, as the liquid metal accumulates in the melting pot, we must have the means of making these changes with facility. For that purpose there is placed in the opening e, a fixed pipe L' L, which, after being bent, descends vertically to L: in its straight portion, which is bored very truly, there is fitted a smaller pipe M M', capable of sliding in its interior like a piston in the body of a pump. The lower extremity N of the pipe M M', has a curb m, upon which is fixed the opening N of the bent N N' of which the other extremity N' is adjusted in the opening; the two curbs m and n are joined and held fast by the two cramps P P. In order to shift the pipe, they loose the screws of the cramps P P, and lift them off, then force up the pipe M M' into the pipe L' L, and remove the pipe N N' into an opening higher. The pipes are then fixed to the cramps and curbs m and n in this new position.

We have thus endeavoured to describe the construction of several forms of the hot blast furnace, and shall conclude this part of our subject, by a

short extract from a very valuable paper, on the hot blast by Dr Clark, of Aberdeen, which was read before the Philosophical Society of Edinburgh in March of the year 1835.

"As nearly as may be, a furnace, as wrought at Clyde Iron works in 1833, had two tons of solid materials an hour put in at the top, and this supply of two tons an hour was continued for twenty hours a day, one half hour every morning, and another every evening, being consumed in letting off the iron made. But the gaseous material—the hot air—what might be the weight of it? This can easily be ascertained thus: I find, by comparing the quantities of air consumed at Clyde Iron works, and at Calder Iron works, that one furnace requires of hot air from 2500 to 3000 cubical feet in a minute. I shall here assume 2867 cubical feet to be the quantity; a number that I adopt for the sake of simplicity, inasmuch as, calculated at an avoirdupois ounce and a quarter, which is the weight of a cubical foot of air at 80° Fahrenheit, these feet correspond precisely with two cwt. of air a minute, or *six tons an hour*. Two tons of solid material an hour, put in at the top of the furnace, can scarce hurtfully affect the temperature of the furnace, at least in the hottest part of it, which must be far down, and where the iron, besides being reduced to the state of metal, is melted, and the slag too produced. When the fuel put in at the top is coal, I have no doubt that, before it comes to this far-down part of the furnace—the place of its useful activity—the coal has been entirely coked; so that, in regard to the fuel, the new process differs from the old much more in appearance than in essence and reality. But if two tons of solid material an hour, put in at the top, are not likely to affect the temperature of the hottest part of the furnace, can we say the same of six tons of air an hour, forced in at the bottom near the hottest part? The air supplied is intended, no doubt, and answers to support the combustion; but this beneficial effect is, in the case of the cold blast, incidentally counteracted by the cooling power of six tons of air an hour, or two cwt. a minute, which, when forced in at the ordinary temperature of the air, cannot be conceived otherwise than as a prodigious refrigeratory passing through the hottest part of the furnace, and repressing its temperature. The expedient of previously heating the blast obviously removes this refrigeratory, leaving the air to act in promoting combustion, without robbing the combustion of any portion of the heat it produces."

Dr Clark concludes his paper by the following statements regarding the Clyde Iron works:—

The Blowing-engine has a steam cylinder of forty inches diameter, and a blowing cylinder of eight feet deep and eighty inches diameter, and goes eighteen strokes a minute. The whole power of the engine was exerted in blowing the three furnaces, as well as in blowing four, and in other cases there were two twyers of three inches diameter to each furnace. The pressure of the blast was two and a half lbs. to the square inch. The fourth furnace was put into operation after the water twyers was introduced, and the open spaces round the blowpipes were closed up by luting. The engine then went less than eighteen strokes a minute in consequence of the too great resistance of the materials contained in the three furnaces to the blast in its passage upwards.

An impression has gone abroad among founders and machine makers, that the iron produced in the hot blast furnace, is inferior in quality to that produced in the cold blast furnace; but correct experiments have, we believe, not yet been performed on the subject. It ought not to be forgotten, that the iron produced by the same furnace, is different at different times, and there is very frequently a difference of quality in the iron of one smelting.

The quality of metal issuing from the smelting furnace, will vary with the quantity of carbon it contains. The quantity of carbon will depend, in a great measure, upon the quantity of charcoal, coke, or coal that has been employed in smelting the ore; and the appearance of the metal, as it flows from the tap hole, will indicate the state of the metal. On the surface of the liquid metal, there floats a substance, called by the workmen *kish*, which has the shining appearance of plumbago, and the presence of this substance, indicates that the metal is saturated with carbon; and if great in quantity, the iron maker immediately takes the hint to diminish, proportionally, the quantity of the ore. The appearance of the cinder, is likewise a good guide, for when it assumes a greenish-yellow colour, it is a proof, that from the want of carbonaceous matter, some of the oxide of iron has not been decomposed. When the oxide of iron is in great excess, the cinder appears of a blackish-green colour. The nature of the iron produced will vary, as before observed, with the manner in which it has been smelted. Some conduct the process in such a way, as to produce iron for the foundry, and others, so as to produce iron for the forge, this latter containing less carbon than the former. The carbon is more abundant in the iron, in proportion as it is soft and tough; and there is this remarkable circumstance in pig and bar iron, or iron for the foundry, and iron for the forge; that the nearer they approach each other in appearance and mechanical properties, the greater is the difference of their chemical composition, at least, so far as carbon is concerned. We cannot enlarge on the distinctions of iron, in this place, to any greater length, but refer the reader to that section of this article, which treats of the chemical properties.

The first step in the process of converting cast or pig iron, into bars of malleable iron, is *refining*. The pigs from the smelting furnace, are placed along with coke, in a smaller furnace supplied with the blasts from the blowing-engine. The coke and pigs are placed in a trough, whose sides are formed of cast-iron plates, but the bottom is of masonry; this trough is surrounded by a sort of canal, in which cold water is kept constantly running. There is a tap hole at one side of the trough, which opens into a rectangular mould at the side of the furnace, which mould is commonly about twenty feet long, and two broad, into which the metal is allowed to run after it has been refined. This mould is likewise surrounded with cold water, as also the blast pipes. The material is set on fire, and the blast kept up until the pig-iron is brought to a state of fusion. The metal is kept in a state of fusion for at least two hours, after which it is run off into the mould, deprived of a great quantity of its carbon, or as the name of the process implies *refined*. The furnace is constructed of such dimension as to yield about a ton of refined metal at each tapping; and it may be stated that the loss of weight by the process, is usually about ten per cent. The sheet of metal which fills the mould to the depth of about two inches, is next withdrawn, and broken

into pieces by means of large hammers, for the purpose of undergoing another process called *puddling*.

A side view of the puddling furnace is annexed ; as will be immediately seen on inspecting the figure.

It is of the reverberatory kind, and formed of bricks. A is the ash pit, over which the grate is laid on which the fuel is placed. B is a door in the side, through which the workman introduces the rod with which he puddles the metal. C is the hearth on which the lumps of metal from the refinery are placed; these are piled on the sides up nearly to the vault, the centre being left open for the flame and smoke to pass out by the chimney D. The chimney is furnished with a damper, in order that the draught may be increased or diminished as may be required. The furnace being heated, the metal begins to melt and flow down to the hearth, the temperature is then lowered, and the workman introduces his long iron rod, and stirs the melted mass, during which it swells and emits carbon, combined with oxygen, which burns with a bluish flame. The metals become thicker as the process advances until it assumes a sandy appearance, at which period the temperature of the furnace is raised, and the particles cohere, when the charge is said to work heavy. The workman now forms it while hot into five or six balls, each of from 70 to 80 pounds weight. The balls are removed and subjected to several blows of a heavy hammer, and formed into what are called *blooms*. The blooms are passed through successive pairs of rollers until they acquire the proper shape of long bars. The loss of weight by this process is generally about 10 per cent.

Five or six of these bars, cut to one length, are now piled together, and placed in a furnace similar to the puddling furnace, and brought to a welding heat, and then taken out and passed through successive pairs of rollers, until the bar is brought to the proper dimensions when the process is finished. The loss of weight is by this last process about 10 per cent.

It may be useful to bring under the reader's eye the actual weight of material employed in the manufacture of one ton of iron.

Raw mine.....3 tons = 2.4 tons of roasted ore.	
Coal for furnace 21 tons = 2.5 of coke.	
Do. for kiln, &c. } ton.	
Engines.....1	
Flax.....1	
8½ tons of materials for 1 ton pig iron.	
Coals for kiln, steam engine, and } 6.53 tons.	
blast furnace.....	
Raw mine.....4.12	
Limestone.....1.37	
	12.02
Add to this } Coals used in refinery .. 61	
Do. in the puddling, &c.1.00	
	2.51

Total, 14.53 tons used in the production of one ton of finished bar.

**Manufacture of Iron in Great Britain**—Iron mines have been wrought in this country from a very early period. Those of the Forest of Dean, in Gloucester-

shire, are known to have existed in the year 1066. In consequence of the great consumption of timber which they occasioned, they were restrained by act of parliament in 1581. Soon after this, Edward Lord Dudley invented the process of smelting iron ore with pit coal instead of wood fuel; and it is impossible, perhaps, to point out an instance of another invention that has proved more advantageous. The patent which his lordship had obtained in 1619, was exempted from the operation of the act of 1623 (21 Jac. I. c. 23.), setting aside monopolies; but though in its consequences it has proved of immense value to the country, the works of the inventor were destroyed by an ignorant rabble, and he was well nigh ruined by his efforts to introduce and perfect his process; nor was it till about a century after, that it was brought into general use. In the early part of last century, well-founded complaints were repeatedly made of the waste and destruction of woods caused by the smelting of iron; and the dearth and scarcity of fuel that was thus occasioned, led, about 1740, to the general adoption of lord Dudley's process for using pit-coal, which was found to be in every respect superior to that previously in use. (*Report of Committee of the House of Commons on Patents*, p. 168, &c. From this period, the progress of the manufacture has exceeded the most sanguine expectations. In 1740, the quantity of pig iron manufactured in England and Wales amounted to about 17,000 tons, produced by fifty-nine furnaces. The quantities manufactured at the undermentioned epochs, in Great Britain, have been as follows:

1750 ..	22,070 tons.	
1788 ..	65,000 —	produced by 85 furnaces
1796 ..	125,000 —	121 —
1806 ..	250,000 —	161 —
1810 ..	406,000 —	unknown.

The extraordinary increase that has taken place in the production of iron since 1823, is principally to be ascribed to the high prices of 1824, 1825, and 1826, when pig iron met with a ready sale at from £9 to £12 and £13 a ton. But, in consequence partly of the failure or postponement of most of the projects as to rail-roads, &c., that were then on foot, and partly of the vast additional supplies which the extension of the manufacture threw on the market, the price fell in 1828, to from £5 to £7 a ton; and continued gradually to decline, till in 1832 it was only worth £4 15s. So heavy a fall had the effect of introducing the severest economy into every department of the manufacture. In despite, however, of all the saving that could be effected in this way, many of the manufacturers were involved in much distress, and the production of iron is believed to have been considerably diminished. This, coupled with the increasing demand for iron, naturally led to a reaction. Prices began to rise early in 1833; and the advance had been such, that in the beginning of 1834, pig iron brought £6 a ton, and the manufacture continues in a state of great activity. The price of iron at present, (January, 1836), varies according to quality from £5 15s. to £7, and seems to be likely to advance in price. This may at first sight appear strange, when the saving to the manufacturer by the employment of the hot blast, and the recent introduction of that rich and productive vein of iron stone called black band, are taken into account. But the truth is, the increased demand for cast iron, in consequence of railway speculations and other causes, far exceeds the increased supply.

The following statement as to the number of furnaces, and the quantity of iron produced in the different districts where the manufacture is carried on, in 1828, and 1830, appeared originally in the *Birmingham Journal*—We have been assured that their accuracy may be depended upon.

Districts.	Number of Furnaces.				Tons of Iron produced.	
	1828.			1830.	1828.	1830.
	Total.	In Blast.	Out.			
South Wales .....	100	89	11	113	279,512	277,643

In Scotland the use of the hot blast has given a great impulse to the manufacture. This has been aided by the introduction of a rich bed of iron stone, called *black band*, which could not be wrought well with the cold air. The number of furnaces in Scotland are :

Place.	Number of Furnaces.	Erecting.	Out.
Glasgow .....	4		
Edinburgh .....	2	4	
Leith .....	4		
Greenock .....	2

Oban .....		2	
Oban (Another work) ..		2	

*Pure Iron.* In specific gravity is 7.7, but it may be made 7.8 by hammering. The specific gravity of cast iron is 7.281; that of steel, 7.795. Under the article *Cohesion*, the tenacity of iron, compared with that of some of the other metals, is given. In malleability, it is much inferior to gold, silver and copper; but in ductility, it approaches these metals, iron wires of one hundred and fiftieth of an inch being frequently drawn. It melts in the extreme heat of chemical furnaces, which equals 158° Wedgewood. We have noticed, under the head of *Native Iron*, the crystalline texture of this metal, as found in nature. A mass of bar iron, which has undergone all the operations of puddling and rolling, after being left in liquid muriatic acid till saturation, presents the appearance of a bundle of fibres, whose fibres run parallel through its whole length. At the two ends of the mass, the points appear perfectly detached from each other, and the fibres are so distinct as to seem to the eye to be but loosely compacted. Iron by friction acquires a peculiar smell, and it possesses the colour distinctively called *iron-gray*. Bars of it, kept in a vertical position, or at an angle of 70° to the horizon, become magnetic spontaneously. They may also be magnetized by percussion, or an electric shock, either from a common machine or a thunder cloud. The magnetic effect is rendered most powerful, in a bar of iron, by allowing galvanic electricity to circulate in circles round it, after being bent into the shape of a horse shoe. A bar, weighing twenty-one pounds, has, in this manner, been made to support a weight of 750 pounds; and the galvanic battery employed consisted merely of two concentric copper cylinders, with a third, of zinc, between them, which were immersed in half a pint of dilute acid. The magnetism of soft iron, however, is not permanent, like that of steel. Iron burns with the greatest facility, as may be seen in the shops of the smiths, where, on withdrawing a bar of iron from the fire, at a white

heat, it emits brilliant sparks in every direction. It is also visible by projecting iron filings upon a lighted candle or a common fire. Its combustion in these cases is the result of its combination with the oxygen of the atmosphere. When it is heated and introduced into a vessel of pure oxygen gas, its combustion is vastly more rapid, and the scintillation which it occasions is extremely brilliant. There are only two non-metallic combustibles, hydrogen and nitrogen, which have not hitherto been combined with iron. Carbon, boron, phosphorus, sulphur and selenium, form with it compounds more or less intimate. The same thing holds of most of the metals. When cold, it is without action on pure water, but decomposes it rapidly when heated to the degree of incandescence. The rusting of iron in a damp atmosphere has been ascribed to the joint agency of carbonic acid and water.

*Compounds of Iron.* Iron unites with oxygen to form three, and, possibly, four *oxides*. The first oxide is obtained either by digesting an excess of iron filings in water, by the combustion of iron wire in oxygen, or by adding pure ammonia to a solution of green copperas, and drying the precipitate out of contact of air. It is of a black colour, becoming white by its union with water in the hydrate, attractable by the magnet, but more feebly than iron. Its composition is,

Iron,.....100.0.....77.82..... 3.5  
Oxygen,.....28.5.....22.18.....1.0

The second or deutoxide of iron is formed by exposing a coil of fine iron wire, in an ignited porcelain tube, to a current of steam, as long as any hydrogen comes over. Its composition is,

Iron,.....100.....72.72  
Oxygen,.....37.5.....27.28

The fourth oxide is obtained by igniting the nitrate, or carbonate of iron, by calcining iron in open vessels, or simply by treating the metal with strong nitric acid, then washing and drying the residuum. Colcothar of vitriol, or thoroughly calcined copperas may be considered as peroxide of iron. This oxide exists abundantly in nature, as may be seen by referring to the preceding account of the *Ores of Iron*. It is a compound of iron, 100, and oxygen, 43. The third oxide has not been satisfactorily established. If the experiments upon its nature are correct, its relation to the others may be perceived in the following statement of M. Berthier, in which the quantities of oxygen combined with the same quantity of metal, in the four oxides, are to each other as the numbers 6, 7, 8, 9. There are two *chlorides* of iron; the first consisting of iron, 46.57 and chlorine 53.43; the second of iron 35.1, and chloride 64.9. The proto-chloride is a fixed, the deuto-chloride, a volatile substance. *Iodine* forms with iron a compound of a light green colour soluble in water. There are two *sulphurets* of iron. The proto-sulphuret is formed by heating equal weights of iron filings and sulphur in a crucible or iron vessel, to incandescence. It is of a dark gray colour, brittle, feebly magnetic. Its composition is iron 28, sulphur 16. It abounds in nature. (See *Magnetic Iron Pyrites*, among the *Ores of Iron*.) The artificial sulphuret varies in composition from the excess of one or the other of its ingredients. It is employed in eudiometry, and is used for the production of sulphureted hydrogen gas, which it evolves copiously on the addition of diluted muriatic or sulphuric acid. The persulphuret of iron is the common iron pyrites found so abundantly in nature. It is composed of iron 28, and sulphur 32. There is also a phosphuret, formed by calcining four parts of phosphate of iron, and one of lampblack, in a covered crucible. It does not act on the magnetic needle;

remains unchanged in the air; is not affected by nitric acid, except it be strong and hot; and is decomposed by charcoal.

*Carburets of Iron.* Carbon unites with iron to form steel, cast iron, and graphite, or plumbago. The proportions of carbon corresponding to different carburets of iron, according to Mr Mushet, are as follow:

1	soft cast steel.
120	
1	common cast steel.
100	
1	the same, but harder.
90	
1	the same, too hard for drawing.
80	
1	white cast iron, or No. 1.
75	
1	mottled cast iron, or No. 2.
70	
1	black cast iron, or No. 3.
65	

Graphite contains about 10 per cent. of iron. It was remarked above, that the magnetism of pure iron is transient. When it is combined with oxygen, carbon, or sulphur, however, it acquires the magnet's coercive virtue, which attains a maximum of force with certain proportions of the constituents, hitherto undetermined. Of the alloys which iron unites with other metals to form, tin plate is the most useful. The surface of the iron plates is cleaned, first by steeping in a crude bran-vinegar, and then in dilute sulphuric acid, after which they are scoured bright with hemp and sand, and deposited in pure water to prevent oxidation. Into a pot, containing equal parts of grain and block tin, in a state of fusion, covered with tallow, the iron plates are immersed in a vertical position, having been previously kept for about an hour in melted tallow. From 300 to 400 plates are tinned at a time. Each parcel requires an hour and a half for the mutual incorporation of the metals. After lifting out the tinned plates, the striae are removed from their surfaces and under edges by subsequent immersion in melted tin, and then in melted tallow, wiping the surfaces at the same time with a hempen brush. Alloys of steel with platinum, rhodium, gold and nickel, may be obtained when the heat is sufficiently high. The alloy with platinum fuses when in contact with steel, at a heat at which the steel itself is not affected. But the most curious circumstances attend the alloy of silver. If steel and silver be kept in fusion together for a length of time, an alloy is obtained which appears to be very perfect, while the metals are in the fluid state, but, on solidifying and cooling, globules of pure silver are expressed from the mass, and appear on the surface of the button. If an alloy of this kind be forged into a bar, and then dissected by the action of dilute sulphuric acid, the silver appears, not in combination with the steel, but in threads throughout the mass, so that the whole has the appearance of a bundle of fibres of silver and steel, as if they had been united by welding. The appearance of these silver fibres is very beautiful. They are sometimes one eighth of an inch in length, and suggested the idea of giving mechanical toughness to steel, where a very perfect edge may not be required. When 1 of silver and 500 of steel are properly fused together, a very perfect alloy is produced, which, when forged, and dissected by an acid, exhibits no fibres, even when viewed with a high magnifying power, though, by dissolving any portion of the mass in acid, and applying a delicate test, the silver is recognised as being every where present. This alloy proves decidedly superior to the very best steel, and its excellence is unquestionably due to the presence of the silver. Various cutting instruments, as razors, penknives, surgical instruments, &c., are now manufactured from it. It is known under the name of *silvered steel*. Equal parts, by weight, of platinum and steel, form a beautiful alloy, which takes a fine polish, and does not tarnish.

The colour is the finest imaginable for a mirror. The specific gravity of the compound is 9.862. The proportions of platinum that appear to improve steel for edge instruments are from one to three per cent. The alloys of steel with rhodium would prove highly valuable, were it not for the scarcity of the latter metal.

*Salts of Iron.* These are possessed of the following general properties: Most of them are soluble in water; those with the protoxide for the base are generally crystallisable; those with peroxide, for the most part, are not so: the former are insoluble, the latter soluble in alcohol. From solutions of these salts ferroproussiate of potash throws down a blue precipitate, or one becoming blue in the air; infusion of galls gives a dark blue precipitate, or one becoming so in the air; hydrosulphuret of potash or ammonia gives a black precipitate; but sulphureted hydrogen merely deprives the solutions of iron of their yellow-brown colour; succinate of ammonia gives a flesh-coloured precipitate with salts of the peroxide. We shall notice these salts individually, in an alphabetical order. *Protoacetate* of iron forms small prismatic crystals, of a green colour and a sweetish taste. *Percetate* of iron forms a reddish brown uncrystallisable solution, much used by the calico printers, and is prepared by keeping iron turnings, or pieces of old iron, for six months, immersed in re-distilled pyroigneous acid. *Protarseniate* of iron exists native in crystals (see *Iron Ores*), and may be formed in a pulverulent state, by pouring arseniate of ammonia into sulphate of iron. It is insoluble. *Percarseniate* of iron may be formed by pouring arseniate of ammonia into peracetate of iron, or by boiling nitric acid on the protarseniate. It is insoluble. *Antimoniate* of iron is white, becoming yellow, insoluble; *borate*, pale, yellow, and insoluble; *benzoate*, yellow and insoluble; *protocarbonate*, greenish and soluble; *percarbonate*, brown and insoluble; *chromate*, blackish and insoluble; *protocitrate*, brown, crystals soluble; *protoferroproussiate*, white, insoluble. The *perferroproussiate* is the beautiful pigment called *Prussian blue*. When exposed to a heat of 410° Fahr., it takes fire in the open air; but in close vessels it is decomposed, apparently, into carbureted hydrogen, water, and hydrocyanate of ammonia, which come over while a mixture of charcoal and oxide of iron remains in the state of a pulverulent pyrophorus, ready to become inflamed on contact with the air. Prussian blue is of an extremely deep blue colour, insipid, inodorous, and considerably denser than water. Neither water nor alcohol have any action on it. It is usually made by mixing together one part of the ferrocyanate of potash, one part of copperas, and four parts of alum, each previously dissolved in water. Prussian blue, mingled with more or less alumina, precipitates. It is afterwards dried on chalk stones in a stove. When sulphuric acid is added to Prussian blue, it makes it perfectly white, apparently by abstracting its water; for the blue colour returns on dilution of the acid; and if the strong acid be poured off, it yields no traces of either prussic acid or iron. *Protogallate* of iron is colourless and soluble; *pergallate*, purple and insoluble; *protomuriate*, green and crystallisable, very soluble; *permuriate*, brown, uncrystallisable, very soluble (see *Chlorides of Iron*, previously described); *protosulphate*, pale green, soluble; *pernitrate*, brown, soluble; *protosulphate*, in green prisms, soluble; *perarsenate*, yellow, scarcely soluble; *protophosphate*, blue, insoluble; *perphosphate*, white, insoluble; *peracetate*, in brown crystals, soluble; *perarseniate*, brownish red, insoluble. *Protosulphate*, or *green vitriol*, or *copperas*, is obtained by putting iron into an aqueous sulphurous acid, and letting them remain

together for some time out of contact with the air. It is generally obtained, however, for the purposes of the arts, not perfectly free from the peroxide, by the following processes:—Native iron pyrites is exposed to air and moisture, when the sulphur and iron both absorb oxygen, and form the salt; or metallic iron is added to sulphuric acid, when diluted, when the union takes place at once. Both methods are practised: the latter is more economical in point of time, and affords a purer salt, but the former is the one most generally adopted. The production of copper from pyrites is conducted in the following manner.—The ore is broken down into pieces of a few inches in diameter, and thrown into large beds, or heaps, of several feet in thickness, disposed on an inclined soil. Water is now let up to the heaps, in moderate quantities, or they are left to derive moisture from rain. The vitriolization immediately commences, and is often attended with a considerable degree of heat. Sometimes the whole mass kindles, which is a disadvantage, as it burns off the sulphur in sulphurous acid vapour, instead of converting it gradually into sulphuric acid to form the sulphate desired. The process goes on well when the pyrites is seen cracking open and becoming covered with a whitish efflorescence. This efflorescence is continually dissolving, from time to time, by the effect of the rains, and the solution trickles down through the heaps, and flows off by gutters to a common reservoir, which is a leaden vessel, generally about seven feet deep, twelve to fourteen long, and six or seven wide, where it is evaporated for several days. As an excess of sulphuric acid often exists in the liquor, a quantity of iron plates or turnings is frequently added for its saturation. From this reservoir, it is run into a crystallizing vat, and there remains for several weeks, at the end of which time the mother liquor is pumped back into the boiler, and the crystals, after draining, are removed from the frames of wood-work on which they have formed, and packed in hogsheads for sale. Instead of going directly from the boiler to the crystallizing pools, the liquor is sometimes allowed to stand twenty-four hours, in a vessel intermediate between these, for the deposition of a sediment of ochre which it contains. Coppers form beautiful green crystals, whose forms and other natural historical characters, as well as composition, have been given under the *Iron Ores* in the commencement of this article. It is used in dyeing and making ink, in the formation of Prussian blue, &c. The *persulphate* of iron is formed by the simple exposure of coppers to the air, especially if in the state of solution, or by boiling the green sulphate with nitric acid. Its colour is yellowish red; uncrystallisable; taste sharp and styptic. The *tartrate* and *pertartrate* of iron may also be formed; and, by digesting cream of tartar with water on iron filings, a triple salt is obtained, formerly called *tartarized tincture of Mars*.

Iron is one of the most valuable articles of the *materia medica*. The protoxide acts as a genial stimulant and tonic in all cases of chronic debility not connected with organic congestion or inflammation. It is peculiarly efficacious in chlorosis. The peroxide and its combinations are almost uniformly irritating, causing heart-burn, febrile heat, and quickness of pulse. Many chalybeate waters contain an exceedingly minute quantity of protocarbonate of iron, and yet exercise an astonishingly recruiting power over the exhausted frame. Their qualities may be imitated by dissolving three grains of sulphate of iron, and sixty-one of bicarbonate of potash, in a quart of cold water, with agitation, in a close vessel.

**IRON CROWN.** A golden crown, set with precious stones, preserved at Monza, in Milan, with which anciently the kings of Italy, and afterwards

the Roman emperors, were crowned, when they assumed the character of kings of Lombardy, has received the above name, from an iron circle, forged from a nail of the cross of Christ, and introduced into the interior of it. Napoleon, after his coronation (1805), established the order of the iron crown. When the emperor of Austria (1815) took possession of the estates in Italy, which fell to him under the name of the *Lombardo-Venetian kingdom*, he admitted the order of the iron crown among the orders of the house of Austria.

**IRON MASK.** See *Mask*.

**IRON-WOOD.** This name is given to the *ostrea Virginica* of America—a small tree, having the foliage of a birch, and the fruit somewhat resembling that of the hop. It is found scattered over the whole of the United States, even as far westward as the base of the Rocky mountains, and is remarkable for the hardness and heaviness of the wood, which, however, has not hitherto been applied to any very important uses, partly on account of its small size. The trunk usually does not exceed six inches in diameter; but the excellent qualities of the wood may, at some future day, be better appreciated. The term *hop-hornbeam*, derived from the form of the fruit, is frequently applied to the species of *ostrea*.

**IRONY**; a term invented by the refined Athenians (*αἰγνία*, dissimulation). By *irony*, we understand, in common life, that more refined species of ridicule, which, under the mask of honest simplicity, or of ignorance, exposes the faults and errors of assuming folly, by seeming to adopt or defend. It neither presupposes a bad heart nor a malicious purpose, and is consistent with so much kindness and true urbanity, that even the object of ridicule may be forced to join in the laugh, or be disposed to profit by the lesson. One mode of irony is, when a person pretends to hold the false opinion or maxim as true, while, by stronger and stronger illustration, he so contrasts it with the true, that it must inevitably appear absurd. Another mode is, when he assumes the mask of innocent *naïveté*, and excites ridicule by the unreservedness of his professions. But humour, concealed under seriousness of appearance, is the foundation of both. (For the Socratic irony, see *Socrates*). There is a certain sort of malicious irony (*persiflage*), the object of which is merely to ridicule, without the desire of correction.

**IROQUOIS**; the name given by the French to the confederacy of North American Indians, called, by the English, the *Five*, and, afterwards, the *Six Nations*. The Mohawks, Oneidas, Onondagas, Cayugas, Senecas, and Tuscaroras were the members of this confederacy. They formerly resided on the Mohawk river and the lakes which still bear their names, and extended their conquests to the Mississippi, and beyond the St Lawrence. Their valour and successes have procured them the name of the *Romans of America*. Their territory abounded with lakes well stored with fish; their forests were filled with game, and they had the advantage of a fertile soil. The sachems owed their authority to public opinion: the general affairs of the confederacy were managed by a great council, composed of the chiefs, which assembled annually at Onondaga. They exterminated the Eries, drove out the Hurons and Ottawas, subdued the Illinois, Miamies, Algonquins, Lenni Lennapes, Shawanese, and the terror of their arms extended over a great part of Canada, and the northern and north-eastern parts of the United States. In the long wars between the British and French, which continued with some interruptions, for nearly a century, until 1763, they were generally in the British interest; and, in the revolutionary war, they were also mostly in favour of the British.

Their numbers have much diminished. Some of the tribes are extinct; some have made considerable advances in civilization, while others have fallen into a state of squalid misery. Some of the nations remained in New York; others removed to Canada. The number in New York, in 1818, was 4575, including the Moheakmunk or New Stockbridge, the Mohicans and Narragansetts, who had been adopted into the confederacy. They owned 265,315 acres of land. See Colden's *History of the Five Nations*; Morse's *Report on Indian Affairs*, New Haven, 1822; *Indians, and Indian Languages*.

IRRATIONAL QUANTITIES are those which cannot be measured by unity or parts of unity; for example, the square root of 2,  $1.4142 \dots$  which, by continued approximation, can be obtained more and more exactly, without end, in parts of unity, but can never be exactly determined. The relation of two quantities is also called *irrational*, when one cannot be exactly measured by the whole and parts of the other. The circumference and the diameter of a circle stand in such an *irrational* relation to each other, because we can only find by approximation, how many times the latter is contained in the former.

IRRAWADDY, or IRAWADDY; a large river of Asia, in the Chinese and Birman empires. Crawford (*Embassy to Ava*, London, 1829) thinks it has its source in the provinces of Lao and Yunnan. According to Wilcox, it is eighty yards broad in lat.  $27^{\circ} 30'$ , where he visited it, and he was informed by the natives that he was fifty miles from its source. It falls, by fourteen mouths, into the bay of Bengal, after having divided into two principal branches, in Pegu, lat.  $17^{\circ} 45'$ . The most easterly branch passes by Rangoon; the most westerly, by Bassien or Pessim. According to Crawford, it is navigable for boats to Bhamo, about 300 miles above Ava. The intermediate space between the eastern and western branches forms a Delta, covered with trees and long grass, and inhabited chiefly by buffaloes, deer, and tigers. In lat.  $21^{\circ} 45'$ , it receives the Keen-Dwem, a considerable river, from the north-west.

IRRITABILITY (*irritabilitas*; from *irrito*, to provoke;—*vis insita* of Haller; *vis vitalis* of Gorter; *occillation* of Boerhaave; *tonic power* of Stahl; *muscular power* of Bell; *inherent power* of Cullen); the contractility of muscular fibres, or a property peculiar to muscles, by which they contract, upon the application of certain *stimuli*, without a consciousness of action. This power may be seen in the tremulous contraction of muscles when lacerated, or when entirely separated from the body in operations. Even when the body is dead, to all appearance, and the nervous power is gone, this contractile power remains till the organization yields, and begins to be dissolved. It is by this inherent power that a cut muscle contracts, and leaves a gap, that a cut artery shrinks, and grows stiff after death. This irritability of muscles is so far independent of nerves, and so little connected with feeling, which is the province of the nerves, that, upon stimulating any muscle by touching it with caustic, or irritating it with a sharp point, or driving the electric spark through it, or exciting with the metallic conductors, as those of silver or zinc, the muscle instantly contracts, although the nerve of that muscle be tied; although the nerve be cut so as to separate the muscle entirely from all connexion with the system; although the muscle be separated from the body; although the creature, upon which the experiment is performed, may have lost all sense of feeling and have been long apparently dead. Thus a muscle, cut from the limb, trembles and palpitates a long time after; the heart separated from the body, contracts when irritated; the bowels, when torn from the body, continue their peristaltic

motion so as to roll upon the table, ceasing to answer to *stimuli* only when they become stiff and cold. Even in vegetables, as in the sensitive plant, this contractile power lives. Thence comes the distinction between the *irritability* of muscles and the *sensibility* of nerves; for the irritability of muscles survives the animals, as when it is active after death; survives the life of the part or the feelings of the whole system, as in universal palsy, where the vital motions continue entire and perfect, and where the muscles, though not obedient to the will, are subject to irregular and violent actions; and it survives the connexion with the rest of the system, as when animals very tenacious of life, are cut into parts; but *sensibility*, the property of the nerves, gives the various modifications of sense, as vision, hearing, and the rest; gives also the general sense of pleasure or pain, and makes the system, according to its various conditions, feel vigorous and healthy, or weary and low. The eye feels and the skin feels; but their appointed *stimuli* produce no motion in these parts: they are sensible, but not irritable. The heart, the intestines, the urinary bladder, and all the muscles of voluntary motion, answer to *stimuli* with a quick and forcible contraction; and yet they hardly feel the *stimuli* by which these contractions are produced, or, at least, they do not convey that feeling to the brain. There is no consciousness of present stimulus in these parts which are called into action by the impulse of the nerves, and at the command of the will; so that muscular parts have all the irritability of the system, with but little feeling, and that little owing to the nerves which enter into their substance; while nerves have all the sensibility of the system, but no motion. After every action in an irritable part, a state of rest, or cessation from motion, must take place before the irritable part can be again incited to action. If, by an act of volition, we throw any of our muscles into action, that action can only be continued for a certain space of time. The muscle becomes relaxed, notwithstanding all our endeavours to the contrary, and remains a certain time in that relaxed state, before it can be again thrown into action. Each irritable part has *stimuli* which are peculiar to it, and which are intended to support its natural action: thus blood is the stimulus proper to the heart and arteries; but if, by any accident, it gets into the stomach, it produces sickness or vomiting. The urine does not irritate the tender fabric of the kidneys, ureters, or bladder, except in such a degree as to preserve their healthy action; but if it be effused into the cellular membrane, it brings on such a violent action of the vessels of these parts, as to produce gangrene. Such *stimuli* are called *habitual stimuli* of parts. Each irritable part differs from the rest in regard to the quantity of irritability which it possesses. This law explains to us the reason of the great diversity which we observe in the action of various irritable parts: thus the muscles of voluntary motion can remain a long time in a state of action, and, if it be continued as long as possible, another considerable portion of time is required before they regain the irritability they lost; but the heart and arteries have a more short and sudden action, and their state of rest is equally so. The circular muscles of the intestines have also a quick action and short rest. The action of every stimulus is in an inverse ratio to the frequency of its application. A small quantity of spirits, taken into the stomach, increases the action of its muscular coat, and also of its various vessels, so that digestion is thereby facilitated. If the same quantity, however, be taken frequently, it loses its effect. In order to produce the same effect as at first, a larger quantity is necessary; and hence the origin of drink-drinking. The more the irritability of a part is accumulated

the more that part is disposed to be acted upon. It is on this account that the activity of all animals, while in perfect health, is much livelier in the morning than at any other part of the day; for during the night, the irritability of the whole frame, and especially that of the muscles destined for labour, viz., the muscles for voluntary action, is reaccumulated. The same law explains why digestion goes on more rapidly the first hour after food is swallowed than at any other time; and it also accounts for the great danger that accrues to a famished person upon first taking in food.

In German philosophy, *irritability*, *sensibility*, and *reproductivity* constitute the whole of organic life. Since the time of Schelling, *irritability* is much considered in the mental philosophy of that country. The French, treating the subject merely with reference to physiology, generally use, at present, the word *contractility* instead of *irritability*.

IRUS; a mendicant of Ithaca, employed by the suitors of Penelope in subordinate offices. On Ulysses' return, when he approached his mansion in the habit of a beggar, in order to surprise those unwary guests, Irus attempted to prevent his entering, and challenged Ulysses to a contest, in which Irus was beaten.

IRVINE, a royal burgh and sea-port in Ayrshire, situated on the left bank of a small river of the same name, the estuary of which forms its harbour; distant from Ayr, eleven miles, N.; from Edinburgh, sixty miles; and from Glasgow, twenty-five, S.S.W. Irvine consists principally of one broad street running parallel with the river, and contains an elegant church surmounted by a lofty spire, a handsome town-house in the centre of the town, and at its northern extremity a commodious academy, where Greek, Latin, French, the mathematics, and various other branches of useful knowledge are taught. Here also are established branches of banks; and a weekly market is held, which is well attended and plentifully supplied with provisions. Irvine was erected into a royal burgh long before the reign of Alexander II., who confirmed its ancient charter. An ample revenue arises from the landed possessions of the burgh and customs of its port, which is commodious, and at spring-tides has about twelve feet water on the bar. The principal article of export is coal, shipped in vessels built and fitted out here, for which purposes there is a yard for ship-building, and a rope-walk, affording employment to a number of the inhabitants, while many others are occupied in a considerable manufacture of leather and cotton. The imports consist chiefly of iron, timber, hemp, flax, and grain, and formerly a great number of boats were employed in the herring fishery, but it has been long on the decline. The parish of Irvine is five miles in length by two in breadth, and the soil in some parts is abundantly productive, though the surface on the banks of the river is flat and sandy. The living is in the presbytery of Irvine (of which it is the seat) and united of Glasgow and Ayr; patron, the Earl of Eglinton, to whom belongs the remains of an old castle in the neighbourhood, said to have been built on the site of an ancient nunnery. Irvine is the birth-place of two distinguished authors, Mr James Montgomery, the poet, and Mr John Galt, the novelist. It was also the temporary residence of Robert Burns, in his early youth, who, it will be remembered, endeavoured to establish himself here in business as a flax-dresser, until his shop was unfortunately burned. Population of burgh and parish in 1831, 5,800.

IS; the Turkish corruption of the Greek *us*, prefixed to many geographical names; as *Ismyr*, from *us* *Σμύρνα* (*Σμύρνα*), *Ismik* (Nice), *Ismid* (Nicomedes).

ISAAC; the son of Abraham, remarkable for his birth, which was long promised to his parents, and took place when they were far advanced in age, and for his having early been destined to perish as a victim on the altar. (See *Abraham*.) He escaped death by a miracle, and resembled his father in faith and steadfastness in the worship of the true God in the midst of heathens, but not in activity and magnanimity. In him the patriarchal character shone milder and softer than in Abraham, but purer and nobler than in his son Jacob. Accustomed to a tranquil life, by the practice of agriculture, which he carried farther than Abraham, and leading a more settled life than his predecessors, yielding and patient in difficulties, he appeared in his family a tender father, but prematurely aged, weak, and easy to be imposed upon, who preferred the quiet, crafty Jacob to the ruder but more honest Esau.

ISABELLA OF CASTILE, the celebrated queen of Spain, daughter of John II., was born in 1451, and married, in 1469, Ferdinand V., king of Arragon. After the death of her brother, Henry IV., in 1474, she ascended the throne of Castile, to the exclusion of her elder sister, Joanna, who had the rightful claim to the crown. During the lifetime of her brother, Isabella had gained the favour of the estates of the kingdom to such a degree that the majority, on his death, declared for her. From the others, the victorious arms of her husband extorted acquiescence; in the battle of Toro, in 1476. After the kingdoms of Arragon and Castile were thus united, Ferdinand and Isabella assumed the royal title of Spain. With the graces and charms of her sex, Isabella united the courage of a hero, and the sagacity of a statesman and legislator. She was always present at the transaction of state affairs, and her name was placed beside that of her husband in public ordinances. The conquest of Grenada, after which the Moors were entirely expelled from Spain, and the discovery of America, were, in a great degree, her work. In all her undertakings, the wise cardinal Ximenes was her assistant. She has been accused of severity, pride, and unbounded ambition; but these faults sometimes promoted the welfare of the kingdom, as well as her virtues and talents. A spirit like hers was necessary to humble the haughtiness of the nobles without exciting their hostility, to conquer Grenada without letting loose the hordes of Africa on Europe, and to restrain the vices of her subjects, who had become corrupt by reason of the bad administration of the laws. By the introduction of a strict ceremonial, which subsists till the present day at the Spanish court, she succeeded in checking the haughtiness of the numerous nobles about the person of the king, and in depriving them of their pernicious influence over him. Private warfare, which had formerly prevailed to the destruction of public tranquillity, she checked, and introduced a vigorous administration of justice. In 1492, pope Alexander VI. confirmed to the royal pair the title of *Catholic king*, already conferred on them by Innocent VIII. The zeal for the Roman Catholic religion, which procured them this title, gave rise to the inquisition (see *Inquisition*), which was introduced into Spain in 1480, at the suggestion of their confessor, Torquemada. Isabella died in 1504, having extorted from her husband (of whom she was very jealous), an oath that he would never marry again. See *Ferdinand V.*, *Ximenes*, and *Columbus*.

ISABELLA; wife of Edward II. of England. See *Edward II.*

ISÆUS, an Athenian orator, born at Chalcis in Eubœa, lived in the first half of the fourth century before Christ, till after 357. Lysias and Isocrates were his teachers. Wholly unconnected with public

affairs, he devoted himself to instruction in eloquence, and wrote speeches for others. Of his fifty orations, eleven are extant, which are recommended by their simple and often forcible style, and are generally on causes respecting inheritance. They are to be found in the 7th vol. of Reiske's *Oratores Græci*. Sir W. Jones translated ten orations of Isæus, with a commentary (London, 1779). The eleventh, now known, has been discovered since.

ISAIAH, the first of the four great prophets, prophesied during the reigns of the kings of Judah, from Uzziah to Hezekiah, at least forty-seven years. Of the circumstances of his life nothing is known, but that he had an important influence over the kings and people. Of the sacred compositions which pass under his name in the Old Testament, that part which is unquestionably his gives him a high rank among the greatest poets. His style is peculiarly appropriate to the subjects of which he treats; it unites simplicity and clearness with the highest dignity and majesty; and in fulness and power, his poetry far surpasses that of all the other prophets. His writings are chiefly denunciations and complaints of the sins of the people, menaces of approaching ruin, and animating anticipations of a more glorious future. The whole bears the stamp of genius and true inspiration, and is marked throughout by nobleness of thought and feeling. See Lowth's *New Translation of Isaiah*, and his *Lectures on the Sacred Poetry of the Hebrews*; also, the article *Prophets*.

ISAURIA, in ancient geography; a country in Asia Minor, forming a part of Pisidia, lying on the west of Cilicia, and on the south of Lycaonia. The inhabitants were shepherds and herdsmen, and formidable as robbers. Their capital, Isaura, was a mere haunt of bandits. The consul Publius Servilius destroyed it; but another Isaura was built not far from it. Hence Strabo mentions two.

ISCHIA (anciently *Pitheculus*, *Enaria*, *Arime*, and *Inarime*); an island in the Mediterranean, six miles from the coast of Naples, about ten miles in circuit. Lon. 13° 56' E.; lat. 40° 50' N.; population, 24,000; square miles, twenty-five. It contains several high hills, one of which is 2300 feet above the sea. It is fertile in fruits, and abounds in game. The white wine is much esteemed. The air is healthy, on which account it is much resorted to by invalids, as it is but a small distance from the continent, and hardly more than four leagues from Naples. It is volcanic; and an earthquake in 1828 destroyed several villages on the island. The porcelain clay of Ischia was prized by the ancients, but the true *terra d'Ischia* is rare. Ischia, the capital town, is situated on the N. coast of the island, and is an episcopal see with 3101 inhabitants.

ISENBURG, or UPPER ISENBURG; a principality in Germany, situated in the Wetterau, about thirty miles long and ten wide, on the borders of the county of Hanau; subject partly to Hesse-Cassel, and partly to Hesse-Darmstadt. Population, 47,457; square miles, 318.—*Iseburg*, a principality belonging to Hesse-Cassel, erected since 1816, contains 16200 inhabitants, and 137 square miles.

ISENBURG, New; a town of Hesse-Darmstadt, in Isenburg, founded in 1700 by French refugees; three miles S. of Frankfurt on the Maine; four S. W. of Offenbach; lon. 8° 38' E.; lat. 50° 3' N.; population, 1170.

ISERE (anciently *Isara*); a river which rises in the Alps, about twelve miles from mount Cenis, in a mountain called *Iseran*, in the duchy of Savoy. After entering France, it passes by Grenoble, St Quentin, Romans, &c., and joins the Rhone about three miles above Valence.

ISERE; a department of France, constituted of

the former Dauphiny. It takes its name from the river Isère, which crosses it. It is divided into four *arrondissements*. Grenoble is the capital. Square miles, 3440; population, 525,984. See *Department*.

ISERLOHN; a town in the Prussian county of Mark, province of Westphalia, on the small river Baaren, with 5500 inhabitants, in 730 houses. The inhabitants are mostly Lutherans, but there are also some Catholics and Calvinists. There is a gymnasium here. It has manufactures of iron, brass, wire, and small wares, as needles, brass scales, &c. More than sixty considerable commercial houses keep up an intercourse with Italy, France, and Germany. There are also woollen and silk manufactories and blancheries in the environs. Iserlohn is about 15 leagues S. of Munster.

ISHMAELITES, in ancient geography and history; the descendants of Ishmael, the son of Abraham by Hagar (q. v.). Ishmael was born 1910 B.C. After the dismissal of Hagar from the house of Abraham, she wandered with her son to the wilderness of Paran, which bordered on Arabia, and here Ishmael became an expert hunter and warrior. His mother procured him a wife from Egypt, by whom he had twelve sons, who became the heads of so many Arabian tribes.

The name of *Ishmaelites*, or *Ismaeliens*, is also given to a Mohammedan sect which originally belonged to the Shiites, the adherents of Ali and the opponents of the Sunnites. In the first century of the Hegira, the Imam Giaffir-el-Sadek, a descendant of Ali, on the death of his eldest son, Ishmael, having transferred the succession to his younger son, Moussa, to the prejudice of the children of Ishmael, a party refused to acknowledge Moussa, and considered Ishmael's posterity as the legitimate Imams. By the Oriental historians, they are reckoned with the Nassarians, among the Bathenins or Bataniens, that is, adherents of the mystical, allegorical doctrine of Islamism. From the 8th to the 12th century, they were powerful in the East. Under the name of *Carmatians* (as they were called, from Carmath, near Cufa, the birthplace of their chief Karfah, in the 8th century,) they devastated Irak and Syria. In Persia, which they likewise overran about this time, they were called *Meladehs*, that is, *imposses*, or *Tahmash*, because they professed Talim's doctrine, that man can learn truth only by instruction. One dynasty of the Ismaelians, founded by Mohammed Abou-Obaid Allah, conquered Egypt about 910, and was overthrown by Saladin, the caliph of Bagdad, about 1177, when the dynasty became extinct with Adh-d-udin-Allah. The other (still existing) Ismaelitic branch founded a kingdom in Syria in 1090, under the Imam Hassan Ben-Sabbah, which became formidable in the East, by its military power. Hassan, with his seven successors, is known in the East under the name of the *Old Man of the Mountain*, because his residence was in the mountain fastness of Mounab in Syria. Thence he despatched his warriors—who were called *Hachichims*, from their immoderate use of the herbane (Arab. *Asachichah*), which produces an excitement amounting to fury—on expeditions of robbery and murder. These Ismaelians, therefore, acquired in the West the name of *Assassins* (corruption of *Hachichims*), which thence became, in the western languages of Europe, a common name for *murderer*. At the close of the 12th century, the Mongols put an end to the dominion of the *Old Man of the Mountain*, who, according to Von Hammer's researches, was not a prince, but merely the head of a sect. From this time, only a feeble remnant of the Ismaelians, from whom proceeded the Druses, about A. D. 1080, has survived in Persia and Syria. J.

Khekh in Persia, an Ismaelian Iman still has his residence, who is revered as a god by the Ismaelians, who extend as far as India, and is presented with the fruits of their robbery, from which he pays a considerable tribute to the shah of Persia. The Syrian Ismaelians dwell around Mesiade, west of Hamah, and in the mountain Semnack on Lebanon; they are under Turkish dominion, with a sheik of their own, who, in consideration of a yearly tribute to the Porte of 16,500 piastres, enjoys the revenues of the country, rendered productive and flourishing by agriculture and commerce (in cotton, honey, silk, and oil). These people are commended by modern travellers for their hospitality, frugality, gentleness, and piety. But their prosperity was interrupted in a war with the Nassarians (q. v.), who took Mesiade in 1809, and desolated the country; and, though reinstated, in 1810, in the possession of their territory, they drag out a miserable existence. The Ismaelians, with other Shiites, adore the prophet Ali as the incarnate God, and Mohammed as an ambassador of God, and the author of the Koran. All Ismaelians term themselves *Seid*, that is, descendants of the family of Mohammed, and wear the green turban, in token of their pretended nobility. In accordance with their exposition of the Koran, they believe in supernatural communications of the Deity by the prophets (Imams), and in the transmigration of souls, drey a paradise and hell, do not observe the purifications and fasts of the orthodox Mohammedans, and perform their pilgrimages, not to Mecca, but to Meschid, the place of Ali's interment, four days' journey from Bagdad. They have no public temples, and their simple rites display more of pure theism than those of the Mohammedans. See the treatise of Rousseau, consul-general in Aleppo, respecting the Ismaelians and Nassarians.

ISIAC TABLE, or BEMBINE TABLE (*Mensa Isiacæ* and *Tabula Bembina*); an ancient Egyptian monument, on which is represented the worship of the goddess Isis, with her ceremonies and mysteries. It is a square table of copper, divided into five compartments, covered with silver mosaic skilfully inlaid. The principal figure of the central group is Isis. After the capture of Rome (1625), this table came into the possession of cardinal Bembo, from whom the duke of Mantua obtained it for his cabinet. After the sack of Mantua in 1630, cardinal Pava obtained it, and presented it to the duke of Savoy. It is at present in the royal gallery at Turin. Several engravings of it have been made; the first by Æneas Vicus (Venice, 1559) in figures, the size of the original. Caylus has engraved and described it in his *Recueil des Antiquités*, vii. p. 34. It is filled with all sorts of hieroglyphics; and this mixture, with other reasons, Spineto considers as a proof of its having been fabricated in Rome, at a late date, by some person who knew little about the science.

ISIDORE; the name of several martyrs, saints, monks, and bishops; among others, of a monk of Pelusium in Egypt, died about the year 449, whose letters are valuable, as illustrative of the Bible. In the history of the papal law, a collection of decretals is worthy of note, which bears on its title page the name of Isidore, archbishop of Seville (who died 436), but which was corrupted in the 9th century by many spurious additions, and was widely circulated from the east of Germany.

ISINGLASS. This substance is almost wholly gelatine. 100 grains of good dry isinglass containing rather more than 98 of matter soluble in water. It is brought principally from Russia. The belluga yields the greatest quantity, being the largest and most plentiful fish in the rivers of Muscovy; but the acunts of all fresh water fish yield more or less fine

isinglass, particularly the smaller sorts, found in prodigious quantities in the Caspian sea, and several hundred miles beyond Astracan, in the Wolga, Yaik, Don, and even as far as Siberia. It is the basis of the Russian glue, which is preferred to all other kinds for strength. Isinglass receives its different shapes in the following manner. The parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, slit open, washed from their slimy sordes, divested of a very thin membrane which envelopes the sound, and then exposed to stiffen a little in the air. In this state, they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple; a thin membrane is generally selected for the centre of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards. Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of its weight, and impairs its gelatinous principles. Isinglass boiled in milk forms a mild, nutritious jelly, and is thus sometimes employed medicinally. This, when flavoured by the art of the cook, is the *blancmanger* of our tables. A solution of isinglass in water, with a very small proportion of some balsam, spread on black silk, is the court plaster of the shops. Isinglass is also used in fining liquors of the fermented kind, and in making mock-pearls, stiffening linens, silks, gauzes, &c. With brandy it forms a cement for broken porcelain and glass. It is also used to stick together the parts of musical instruments.

ISIS; the principal goddess of the Egyptians, the symbol of nature, the mother and nurse of all things. According to Diodorus, Osiris, Isis, Typhon, Apollo, and Aphrodite (Venus) were the children of Jupiter and Juno. Osiris, the Dionysos (Bacchus) of the Greeks, married Isis (sun and moon) and they both made the improvement of society their especial care. Men were no longer butchered, after Isis had discovered the valuable qualities of wheat and barley, which had till then grown wild, unknown to mankind, and Osiris taught how to prepare them. In gratitude for these benefits, the inhabitants always presented the first ears gathered as an offering to Isis. Whatever the Greek related of his Demeter (Ceres) the Egyptian attributed to Isis. As agriculture was improved, civilisation advanced, and a taste for art and letters was developed. At least, we first hear among the Egyptians, of the building of cities and temples, and the constitution of the priesthood, after the time of Isis, who was also revered as the inventress of sails. According to Plutarch's learned treatise (on Isis and Osiris), Osiris and Isis were the illegitimate offspring of Saturn and Rhea. When Helios (Sol), the husband of Rhea, discovered the intrigue, he pronounced judgment upon her, that she should not be delivered in any month nor in any year. Mercury, who was then in love with Rhea, and was loved by her, having heard the curse, discovered a way in which she might be delivered, notwithstanding. In playing at draughts with the moon, he won from her the seventieth part of her light, of which he made five days, and, having added them to the 360, of which the year had previously consisted, gave the goddess time for delivery. These were the intercalary days of the Egyptians, which were celebrated by them as the birthdays of their deities. Osiris was born the first; and at his birth a voice cried, "The lord of the world is born." On the second day, Rhea was delivered of Arotheris, or the elder Horus (Apollo), on the third of Typhon, on the fourth of Isis, and on the fifth of Nephthys, who was called *Teleute*, the Consummation, though others give her the name of *Aphrodite* and *Nikê* (Victory). Of

these five children, there were three fathers—Helios, Saturn, and Mercury. Typhon married Nephthys; Osiris and Isis loved each other even in their mother's womb. Osiris, the good spirit, was persecuted by Typhon the bad spirit, who, by stratagem, shut him up in a chest, and threw him into the sea. When Isis learned this, she cut off one of her locks, put on mourning garments, and wandered about disconsolate, in search of the chest. Meanwhile she learned that Osiris, on a certain occasion, deceived by Nephthys, who was enamoured of him, had mistaken Nephthys for herself, and that the child which was the fruit of this union had been exposed by its mother. Isis therefore sought the child, and bred him up under the name of *Anubis*. The chest in which Osiris was shut up, was, meanwhile, driven ashore at Byblos, and thrown on a bush, which, having suddenly grown into a beautiful tree, had entirely enclosed it. This tree was afterwards cut down by the king of the country as a curiosity, and used as a pillar in his palace. The chest was finally obtained by an artifice of Isis, but the body, being afterwards discovered by Typhon, was torn by him into fourteen pieces. On discovering this, Isis proceeded to collect the fragments; she found them all but one, an image of which she therefore formed; and thus the Phallus came to be held sacred, and a festival was instituted in its honour by the Egyptians. Osiris having returned to life, Isis bore him, prematurely, Harpocrates, the god of silence, who was lame in his lower limbs. Horus, the son of Isis, afterwards vanquished Typhon in a war, and gave him to his mother for safe keeping. She set him at liberty, on which account Horus tore the crown from her head, instead of which Mercury gave her an ox's head. As the goddess of fecundity, and the universal benefactress, she superintended the cure of human maladies, and, even in Galen's time, several medicines bore her name. After her death, she was revered as the chief of the divinities. According to Herodotus, the Egyptians represented Isis under the form of a woman, with the horns of a cow, as the cow was sacred to her. Another tradition also related, that Isis, in the shape of a young cow, became the mother of Apis, by a ray from heaven (Osiris); that is, the sun and moon sustain the earth. She is also known by the attributes of the *lotus* on her head, and the *sistrum* in her hand, a musical instrument, which the Egyptians used in the worship of the gods. The dress of Isis consists of a close under garment, and a mantle drawn together and fastened in a knot on her breast. Her head is covered with the Egyptian hood. Sometimes, like the Diana of Ephesus, the universal mother, she is represented with a great number of breasts. Among the Romans, Isis afterwards received, in countenance, figure, and dress, somewhat of the character of Juno. A foreign character is to be recognised only in the mantle and fringed veil, and other attributes. She was particularly worshipped in Memphis, but at a later period, throughout all Egypt. A festival of eight days (the festival of Isis) was annually solemnised in her honour, consisting of a general purification. (See *Mysteries*.) It was introduced into Rome, but frequently prohibited on account of the abuses which it occasioned. Under Augustus, the temples of Isis were the theatres of the grossest licentiousness. From Egypt, the worship of this goddess passed over to Greece and Rome. See *Isis*, also *Egyptian Mythology* in the article *Hieroglyphics*.

ISLAM, or, as it is pronounced in Syria, *Eslem*, signifies an entire submission or devotion to the will of another, and especially of God, and thence the attaining of security, peace, and salvation. This act is performed, and these blessings are obtained, accord-

ing to the doctrine of the Koran, by acknowledging the unity of God, and the apostleship of Mohammed. Every man who makes this profession (*aslama*) is a *Moslem*, i. e. has entirely given himself up to the will of God, and is, on that account, in a state of salvation (*salam*). But as *Muslimāni*, the dual of *Muslim*, is commonly substituted for the singular by the Persians and Turks, the word *Muslimān*, or *Musliman*, has in those, as well as in the European languages, now nearly superseded the shorter and more correct term.

As *Islam* comprehends the practical as well as the doctrinal tenets of the Mohammedan religion—every thing which Moslems must believe and practise—embraces the whole of their civil and religious polity; for the system of Mohammed relates more to this world than the next, and was designed, like the law of Moses, for the secular as well as the spiritual direction of his followers. But, taken in its more common and direct sense, it signifies the profession of the five fundamental doctrines, on which, according to a traditional declaration of the prophet (Rehmad, *Rel. Moh.* I. l. p. 5.) the whole edifice of the faith is built. Those five points are—1. the acknowledgment of the Divine Unity and of the prophetic mission of Mohammed; 2. observance of prayer; 3. giving of alms; 4. keeping the fast of Ramadan; and, 5. the performance, if possible, of the pilgrimage to Mecca. They are often, also, subdivided and enlarged, in order to arrange them more conveniently into the two classes of belief (*iman*) and practice (*dein*). The former relates to—1. God; 2. the angels; 3. the Sacred Book; 4. the prophets; 5. the last day; and, 6. the divine decrees: the latter, to—1. purification; 2. prayer; 3. alms; 4. fasting; and, 5. the pilgrimage. To the first article of this creed, the Persians and other adherents of Ali add, "Ali is the vicar of God;" and that is the only essential point in which they differ from the Sunnites, or orthodox Moslems, who acknowledge the authority of the four first khalifs. The disputes concerning the succession to the khalifate, or supremacy of the prophet, spiritual and civil, which arose immediately after his death, split his followers, as is well known, into two distinct sects, the Sunnites and the Shiites, who have never since ceased to hate each other with a cordial animosity; but they differ more in the degree of veneration paid to Ali, than in any other point; and, professing the same creed, with the exception of one article, they derive their doctrines from the same sources. In their respective rituals, and their interpretation of particular texts, there are many minor differences; but both agree in superadding a traditional to the written law of Mohammed, and both have sanctioned that departure from the original simplicity of his doctrine, the re-establishment of which was the professed object of the Wahabees. See *Mohammed*.

ISLAND; a portion of land less than a continent, and which is entirely surrounded by water. Islands are of very different extent, surface, &c. There are some so large, that authors have doubted whether they should not be called continents, as New Holland; this, however, is a mere matter of definition. Borneo, Java, Madagascar, Sumatra, Sicily, Great Britain, Ireland, Iceland, Hayti, Cuba, Newfoundland, are among the most considerable islands, and are capable of containing powerful states; while others, speaking only of those which are inhabited, are only of a few miles in diameter. They differ not less in form than in extent, some being indented with deep bays, and affording fine harbours, and others presenting an almost unbroken line of coast. A cluster of several islands is called an *archipelago*. (q. v.) The principal clusters in the Atlantic are the West Indies, the Azores, the Canaries, the Il-

brides, Orkneys, Shetlands, &c. But the great world of islands is in the Pacific, and modern writers have considered them as forming a fifth division of the world, including the Eastern Archipelago, Polynesia, and Australia, to which they have given the name of *Oceania*. (See *Oceania*.) A large island is a continent in miniature, with its chains of mountains, its rivers, lakes, and is often surrounded by a train of islets. The rivers of islands are in general little more than streams or torrents, and the smaller islands are often uninhabitable from want of water; but they serve as haunts and breeding-places of innumerable sea-birds. There are islands in rivers and lakes, as well as in the sea. In rivers, they are often formed by the division of the stream into various branches, and often by accumulations of earth brought down and deposited around a rocky base. Examples are not wanting of floating islands, which are formed by the roots of plants and trees interlacing with each other, and thus constituting a support for deposits of successive layers of earth. Chains of islands in the neighbourhood of continents seem to be often formed by the action of the waters washing away the less solid parts, which once occupied the spaces between the mountains and rocks which still appear above the surface of the waves. Single islands in the ocean, such as St Helena, Ascension, &c., and some clusters, as the Canaries, the Azores, &c., appear to owe their origin to the action of submarine fire, which has raised them above the level of the sea. Considerable islands have been known to be suddenly raised from the bed of waters, and soon after to have as suddenly disappeared in the ocean. The Pacific contains a great number of low islands formed of coral reefs, which are sometimes covered with sand, on which a few plants find nourishment. These reefs are formed by the labours of innumerable zoophytes. Submarine islands, as they have been sometimes called, or immense banks of sand, above which there is no great depth of water, are not unfrequent. It has been remarked that islanders have generally some peculiar traits of character, which distinguish them from the inhabitants of continents: it is true that they have often been distinguished by their commercial activity, and their naval skill; but this trait is common to other inhabitants of countries bordering on the sea. The great commercial powers of ancient times were the Phœnicians, the Carthaginians, and continental Greeks; of the middle ages, the Italian republics; and the Normans were the most distinguished naval warriors of their time.

A portion of country nearly included between several rivers, is sometimes called an *island*, as the ancient province of the *Ile de France*. The Greeks called such a district by the expressive name of *Μετρωπαια*. The Greek word for island is *νησος*, the Latin *insula*, Italian *isola*, Spanish *isla*, French *île*, *ilot*, German *insel* and *eiland*, Danish, *ø*, and *ey*, Swedish *ø*, Russian *ostrov*.

ISLAND or ICELAND SPAR. See *Lime*.

ISLANDS OF THE BLESSED, or FORTUNATE ISLANDS (*Insula Beatiorum*, *Fortunatarum*, *Insula*, *Nova Manana*); the Elysium of Homer; according to the Grecian mythology, the happy islands which were supposed to lie westward in the ocean, where the favourites of Jupiter, snatched from death, lived in the midst of happiness. According to Hesiod, they were the residence of the fourth race of heroes. In the earliest mythology, the Islands of the Blessed, the Elysian Fields, and the lower world, were in general confounded with each other.

ISLAY or ILAY, a large island in Argyleshire, the most southern of the Hebrides. Its extreme length from the point or Mull of Oa to Rùmhill, that is, from south to north, is nearly thirty-one English

miles, and its breadth, from the point of Ardmore on the east to the form of Saraig, and the opposite extremity of the Rinn on the west, is about twenty-four miles. Its total superficies is about 154,000 acres. It is divided into three parishes, namely, Bowmore or Killarow, Kilchoman, and Kildalton. It is separated from the island of Jura, on the north-east, by a narrow sound formed by the Atlantic Ocean, which bounds it on every side, and is said to have derived its name either from Isla, the daughter of a king of Lochlin, whose ashes repose at Kildalton, or Isla, i. e. the isle, from its having been the chief seat of the Lords of the Isles, till their sovereignty was overthrown by James III. A feu duty of £500 per annum was paid to the crown for this island by the family of Calder, who possessed it from 1626 to 1719. In the latter year, it was purchased, with the exception of a farm or two, by Mr Campbell of Shawfield, for £12,000, and still remains in the hands of his descendants. Its annual rental must now exceed its original purchase money. The last proprietor has done much for the improvement of the island; but of late years an excessive increase of rent has caused the emigration of many old tenants. The coast, though rocky and dangerous, is indented by several safe bays and harbours, that of Loch Indal, affording secure anchorage, off the populous village of Bowmore, for ships of large burden, and having a commodious quay, with good landing places. In the centre of the island is Loch Finlaghan, three miles in circuit, surrounding an islet of the same name, where are vestiges of the palace in which the Macdonalds, lords of the isles, once resided in all the pomp and splendour of royalty, and who were here crowned, anointed, and enthroned on a square stone by the bishops of Argyle, in the presence of their subordinate chieftains. There are several other lakes, besides numerous streams, all abounding with salmon and trout. The crops raised in Islay are principally of barley and oats, and much of the grain is used in the distillation of whiskey. Agriculture is practised here with as much skill and success as in the Lowlands, and good roads and good farm houses are abundant. The island is rich in minerals. Lead, copper, and iron ores, with quicksilver, limestone, and marl, are obtained here. It is a favourite resort for eagles, falcons, geese, ducks, and various other species of birds; and otters, hares, weasels, vipers, &c., are frequently found upon the island. Islay has long been celebrated for the excellence of its distillation of whiskey. Population in 1831, 19,700. See *Hebrides*.

ISLE OF FRANCE. See *France*, *Ile of*.

ISLINGTON, a village of England, in the county of Middlesex, and neighbourhood of London, is chiefly composed of the dwellings of retired citizens, and other persons connected with the capital. The neighbourhood abounds with pleasant walks, the fields being unenclosed, and intersected by the meanders of the New river, while the adjacent tea-gardens and taverns, all in fine open situations, and furnished with bowling-greens, are much visited from the metropolis. Population of the parish, 37,316. See *London*.

ISMAIL, or ISMAILOW; a town in Russia, in Bessarabia, on the north side of the Danube, about thirty-three miles from the Black sea; 144 S. W. Otchakov, 268 N. Constantinople; lon. 28° 50' E.; lat. 45° 21' N. Population 10,000. The town of Ismail contains seventeen mosques, and measures about a mile towards the land, and half a mile by the side of the Danube, and was fortified by eight bastions. The ramparts are, in general, eighteen feet in height, in some parts twenty-five. This place was taken by storm (December 22, 1790), by the Russians, under general Suwarrow. The Russians were several

times repulsed, and lost, in the siege, 10,000 men. According to the account, as published at Petersburg, the Turkish garrison were put to death after the surrender, and 30,000 men massacred in cold blood. The booty found was immense—230 pieces of cannon, many magazines, powder, bombs, and balls, 345 standards, an abundance of provisions, 10,000 horses, &c., to the value, as calculated, of 10,000,000 piastres.

ISOCRATES; one of the most distinguished Greek orators, born at Athens, 436 B. C. His principal teachers were Gorgias, Prodicus, and Protagoras. On account of his weak voice and natural timidity, he was reluctant to speak in public; but he applied himself with the greatest ardour to instruction in the art of eloquence, and preparing orations for others. He derived a considerable profit from this occupation, as is evident from the fact, that he received a present of twenty talents (about 18,000 dollars) for a speech that he wrote for Nicocles, king of Cyprus. In his childhood, he was the companion of Plato, and they remained friends during their whole lives. He had a great veneration for Socrates. After the death of Socrates, which filled his scholars with fear and horror, he alone had the courage to appear in mourning. He gave another proof of his courage, by publicly defending Theramenes, who had been proscribed by the thirty tyrants. This courage, however, seems to have deserted him; for he never after ventured to appear publicly and take part in the popular assemblies. This was the reason why he never attained to the offices, to which, in Athens, public eloquence afforded the only passport; but eloquence, nevertheless, owed much to his services. He was particularly distinguished for a polished style and a harmonious construction of his sentences. The composition, revision, and repeated polishing of his speeches, occupied so much time, that he published little. His celebrated panegyric on Athens (*Panathenæus*) employed him ten years. The critics of his time objected to him, that his style was often prolix and overloaded with ornament; that he aimed rather at pleasing the ear than moving the heart; that he made the sense subservient to the sound, and often used unmeaning expressions and inappropriate figures to round off his periods. As all his speeches were modelled after the same pattern, their sameness excited weariness. His subjects were the most important points of morals and politics. His admonitions to princes were so gentle, that they could not be offended by them, and even bestowed favours on the author. He knew how to flatter them in the most delicate manner. A proof of this is afforded by the letter which he wrote, when ninety years of age, to the Macedonian king Philip. Yet his desire for the freedom of Greece was so intense, that he starved himself to death, in his ninety-eighth year, from grief at the unhappy battle of Cheronæa. In Plutarch's time, sixty orations went under his name, not half of which were, however, deemed genuine. Twenty-one now remain, of which the principal are the *Panegyricus* (an oration in which he exhorts the Greeks to concord, and to war against the Persians, edited by Morus and Spohn, Leipsic, 1817, Piniger and Dindorf, 1825 and 1826), and the *Panathenæus*. Ten letters are also extant. The latest editions of all his orations are those of Lange (Halle, 1803) and of Coray (Paris, 1806, two volumes). Of the older editions, those of H. Wolf, of Henry Stephens, Bekker, and Battie are the best.

ISOGRAPHY (from the Greek *isos*, equal, similar, and *graphein*, to write); the imitation of handwriting. As it is too expensive and difficult for many persons to collect autographs (q. v.) of famous persons, it is agreeable to have at least fac-similes or isographs.

An interesting work was completed in the year 1831 called *Isographie des Hommes célèbres* (Paris), containing several hundred fac-simile copies of autograph letters and signatures. Some years ago, Mr. Tinsley published a work under the title *British Autography*, containing a collection of portraits of celebrated English characters, with the fac-simile of their autographs under each; and Mr. Nichols is publishing another work of the kind. It has been often asserted, that some judgment could be formed of a man's character from his handwriting, and there exists a small French publication—*L'Art de juger les Hommes par leur Ecriture*—a new reason for authors to be thankful for the invention of printing.

ISOUARD, NICOLÒ. See *Nicolo*.

ISPAHAN, ISFAHAN, or SPAHAWN (anciently *Aspadana*); a city of Persia, in Irak, formerly the capital of the whole country; 260 miles N. E. Basra. lon. 51° 50' E.; lat. 32° 25' N. The population was formerly estimated by some travellers, probably with much exaggeration, at 1,100,000. Chardin, in 1686, stated it at 600,000. According to Olivier, it was reduced, in 1796, to 50,000. In 1800, it was stated at 100,000. Morier stated it in 1810 from Persian authorities, at 400,000; but, in his second journey, at 60,000. Kinnier states it at 200,000. According to Chardin, the walls were twenty-four miles in circuit, and contained 122 mosques, forty-eight colleges, 1802 caravansaries, and 273 public baths. A great part of the city is a present a mass of ruins, with here and there an inhabited house. It is situated on the river Zenderoud. Under the caliphs of Bagdad, it became the capital of the province of Irak. Being situated in the centre of the empire, and surrounded by the most fertile territories, it soon became a place of great population, wealth and trade. In 1387, it was taken by Timur Bec, and the citizens were given up to indiscriminate massacre, and 70,000 are said to have perished. Shah Abbas made it the seat of his empire, and spared no cost in embellishing it with the most splendid edifices. In 1722, it was taken by the Afghans; but, in 1727, it was retaken by Nadir Shah, since which it has not been a royal residence. The great palace built by Shah Abbas, is said to have been five miles in circuit, a great part of which space, however, was laid out in ten gardens, adorned with summer houses and other elegant structures. The walls and buildings of this palace remain nearly entire, but it has been stripped of nearly all its costly furniture, and every thing valuable that could be removed. The square called Meyden was equally distinguished, one third of a mile in length, formerly encircled by a canal, bordered with plane trees; but all vestiges of both are now obliterated. Another remarkable object is the Chaur Baug (four gardens), a name given to an avenue of more than a mile reaching from the Meyden to the mountains east of Isphahan, composed of four rows of large and beautiful plane trees, with canals and basins to receive the waters of the Zenderoud. There are several handsome bridges in the city, and the mosques display great magnificence. The private buildings have a mean appearance, built of bricks dried in the sun, but within they are handsome and convenient. The streets are narrow, winding, irregular, unpaved, and very dusty. When Isphahan was in its prosperity, its suburbs were distinguished for their extent and beauty. The principal one, Julfa, is now reduced from 12,000 to 600 families—Armenians, Circassians and Georgians. The manufactures of the city are still extensive, and it is famous for its gold brocade. It is also the emporium of the inland commerce of Persia.

ISRAEL and ISRAELITES. See *Israel* and *Hebreus*.

ISRAELITE CHRISTIANS; the Jews converted to Christianity in Russia. An imperial decree of March 25, 1817, imparted to them perfect freedom in the choice of their Christian confession, portions of the public lands for the establishment of colonies, freedom to exercise mechanical arts without restraint, full civil rights, independence of the local authorities, government by magistrates chosen by themselves, who were immediately subordinate to an imperial board of control, exemption from military and civil service, from furnishing quarters to soldiers, from supporting the posts, and from all taxes for twenty years, when they are to be placed on an equality with other subjects. According to the denomination of the Christian confessions selected by them, they must form distinct parishes, in which no foreign Christian or Jew may settle, though every foreign proselyte may be admitted after the payment of his debts.

ISSUE. The plaintiff and defendant, in a suit at law, are said to be *at issue*, when something is affirmed by one of them, which is denied by the other. The subject of this affirmation and denial may be either matter of fact or matter of law. If the defendant intends to dispute the truth of the statement whereon the plaintiff grounds his complaint, he denies either the whole of the statement, or some one material fact contained in it, which, in technical language, is called *traversing*. He then appeals to the decision of a jury, which is called *putting himself upon the country*. Although the plaintiff's statement be true, it does not necessarily follow that it discloses sufficient grounds for complaint against the defendant. If it does not so, the defendant admits the truth of the facts, but denies their sufficiency in law to support the action. In this case, he appeals to the decision of the judges; for the jury merely decides questions which involve matters of fact. Questions of mere law fall beneath the cognizance of the judges. When either the plaintiff or the defendant admits the facts, but denies the law of the other, he is said to *demur*. Although the plaintiff's statement, so far as it goes, be both true in point of fact, and sufficient in point of law, the defendant may still have a good defence; for the plaintiff may have stated the truth, but not the whole truth. Some facts may be suppressed, which, when explained by the defendant, may turn the scale in his favour. If this counter-statement of the defendant is sufficient in point of law as a defence, the plaintiff demurs; but if it is sufficient in point of law, he must either deny the facts, or allege some other facts to counterbalance them. By these means, the parties in the cause must ultimately arrive at some point, either of law or fact, at which they are at issue, and judgment will be given for that party in whose favour the issue is decided. The statements and counter-statements of the parties are called the *pleadings*, and each particular stage in the pleadings has a name appropriated to itself. These names are, 1. the *declaration*; 2. the *plea*; 3. the *replication*; 4. the *rejoinder*; 5. the *sur-rejoinder*; 6. the *rebutter*; 7. the *sur-rebutter*. The first, third, fifth, and seventh names belong to the pleadings of the plaintiff; the second, fourth, and sixth to the defendant. Issue is generally taken before the parties arrive at a *sur-rebutter*. In former times, the pleadings were conducted, *vivâ voce*, in open court, and the judges resided, like moderators, during the dispute, until the parties arrived at an issue; but they are now drawn up in writing out of court, and are then filed by the attorneys in the proper offices attached to the court. The judges now hear nothing of them until the issue of fact comes on for trial, or the issue at law for argument. If the existence of a particular record

is put in issue, it must be produced by the party who affirms its existence; and the court, at the time appointed for its production, decides the issue without the intervention of a jury. This is one of the very rare cases where the jury are not the sole judges on questions of fact. There is a rule of pleading, that only one material fact shall be put in issue in one plea. To this rule the *general issue* forms a wide exception. When a special plea is pleaded, evidence is only admissible as to the truth or falsehood of the particular fact which is the subject of that plea; but the general issue is a species of plea which usually compels the plaintiff to prove his whole case to the satisfaction of a jury, and, at the same time, enables the defendant to prove any circumstances whatever which discharge his liability. Thus, if an action be brought against a man for the price of goods which the plaintiff alleges that the defendant bought, if the defendant has become a bankrupt since the purchase, he may plead that fact specially, and then the evidence is confined to the single question—Has he or has he not become bankrupt? But if he pleads the general issue, then he may prove either that he never bought the goods, or that he paid for them, or that he returned them to the plaintiff on finding them to be of an inferior quality, or, in short, any thing else which is a bar to the action. The form of the general issue, in this case, is simply "that the defendant did not promise or undertake in manner and form as the plaintiff has complained against him." Owing to this latitude allowed to the general issue, it sometimes happens that plaintiffs are taken by surprise at the trial, by the defendant setting up an unexpected defence, which the plaintiff, on the spur of the moment, is unable to disprove. When this is proved to the satisfaction of the judges, they will, if the justice of the case require it, grant a new trial.

ISTAKHAR. See *Persæpolis*.

ISTAMBOL. See *Constantinople*.

ISTHMIAN GAMES; so called because they were celebrated on the isthmus of Corinth, which joins the Peloponnesus to the continent. On it was a famous temple consecrated to Neptune, near which the Isthmian games were celebrated. On one side of the temple were the statues of the victors in these games, and on the other was a grove of pines. In the temple stood four horses, gilded all over, with the exception of their ivory hoofs: by the side of the horses were two Tritons, the upper parts of which were gilt, and the rest of ivory. Behind the horses was a car, with the statues of Neptune and Amphitrite, of gold and ivory. Not far from the temple were a considerable theatre, and the stadium, of white stone, in which the games were celebrated. The whole isthmus was sacred to Neptune, who was thence called *Isthmius*. According to the common opinion, the Isthmian games were founded in honour of Palæmon or Melicerta. (See *Ino*.) Others relate that Theseus established them in honour of Neptune. They were originally held in the night, and had perhaps fallen into disuse, when Theseus restored them, and ordered them to be celebrated in the day. As Theseus was either the founder or the restorer of these games, the Athenians had the precedence in them. All Greece took part in them, excepting the Eleans, whose absence was thus explained:—As the sons of Actor were riding to these games, they were killed, near Elea, by Hercules. Their mother, Melione, discovered the murderer, who then resided in the territory of Argos. She, therefore, demanded satisfaction of the Argives, and, on their refusal to grant it, requested the Corinthians not to admit them to the games, as disturbers of the public tranquillity. As they would not yield to her solicitations, Melione pronounced direful curses on all the Eleans, if they

should ever participate in these games. They were celebrated, with the same splendour as the Olympian and other public games, twice in each Olympiad, probably in autumn: the athletic exercises were the same. The victors were at first adorned with wreaths of pine branches, but afterwards with wreaths of dry and faded ivy. The pine wreaths were afterwards resumed. The following represents an Isthmian Crown:—

ISTRIA (anciently *Histria*); a province of Austrian Italy, in Illyria; bounded on all sides by the sea, except towards the north, where it is joined to Carniola. It was anciently a part of Illyricum. Population, 140,749; square miles, 1570; of this, more than two thirds formerly belonged to the republic of Venice. It is a rich, fertile tract. The occupation of the inhabitants consists in agriculture, the culture of wine and oil, the rearing of bees, the manufacturing of silk, leather, tallow, salt, and also in fishing. The chief towns are Rovigno, Capo d'Istria, and Fiume. Istria was confirmed to Austria in 1814.

ITALY, once the seat of universal empire, but which, since the overthrow of the Roman power, has never formed an independent whole, the pride of its inhabitants and the admiration of foreigners, on account of its delicious climate and former renown, is a narrow peninsula, extending from the Alps (46° to 38° N. lat.) into the Mediterranean sea, which, on the east side of Italy, is called the *Adriatic*; on the west, the *Tuscan* sea. The Apennines (q. v.), rising near the maritime Alps (q. v.) are the principal chain of mountains, and stretch through the country, dividing Lombardy from the Genoese territories and Tuscany, and Tuscany from Romagna, intersecting the States of the Church, and running through the kingdom of Naples to the strait of Messina. Upper Italy (Lombardy) is remarkably well watered. The Po, which receives a great number of rivers from the large lakes at the foot of the Alps (lago Maggiore, di Lugano, di Como, d'Iseo and di Garda), and the Adige, are the principal rivers. They both rise in the Alps, and flow into the Adriatic sea. In Middle Italy (Tuscany and the states of the Church), are the Arno and the Tiber, which rise in the Apennines, and flow into the Tuscan sea. In Lower Italy (Naples) there are no large rivers, on account of the shortness of the course of the streams from the mountains to the sea: the Garigliano is the principal. The climate is warm, without excessive heat, and generally salubrious. The winter, even in Upper Italy, is very mild: in Naples, it hardly ever snows. The abundance and excellence of the productions of the soil correspond with the beauty of the climate. In many places, both of the north and south, there are two and even three crops a year. The volcanic character of the coasts of Lower Italy is particularly remarkable in a geological point of view, especially in the region of Puzzuoli and Vesuvius. The neighbouring islands of the Mediterranean are distinguished by the same character. The present number of inhabitants is much inferior to the former population of this delightful country. The following table, copied from Mr Balli's different publications, is taken from the *Revue Britannique*:

Political Divisions.	Surface in sq. Mts. or to the Degree.	Population in 1827.	Revenue in 1827.	Area in 1827.

The national character of the Italians, naturally cheerful, but always marked by strong passions, has been rendered, by continued oppression, disorganizing and selfish. The Italian, moreover, possesses a certain acuteness and versatility, as well as a love of money, which stamp him for a merchant. In the middle ages, Venice, Genoa, Florence and Pisa were the chief marts of the European commerce with the East Indies; and Italians (then called *Lombards*, without distinction, in Germany, France, and Britain) were scattered all over Europe for the purposes of trade. The discovery of a passage by sea deprived them of the India trade, and the prosperity of these republics declined. The Italian, restricted almost solely to traffic in the productions of his own country, has nevertheless always remained an able and active merchant. Before Rome had (2100 years ago) absorbed all the vital power of Italy, this country was thickly inhabited, and, for the most part, by civilized nations. In the north of Italy alone, which offered the longest resistance to the Romans, dwelt a barbarous people, the Gauls. Farther south, on the Arno and the Tiber, a number of small tribes, such as the Etrusci, the Samnites and Latins, endeavoured to find safety by forming confederacies. Less closely united, and often hostile to each other, were the Greek colonies of Lower Italy, called *Magna Græcia*. The story of the subjection of these nations to the Roman ambition, belongs to the history of Rome. Italy, in the middle ages, was divided into Upper, Middle, and Lower Italy. The first division comprehended all the states situated in the basin of the Po; the second extended between the former and the kingdom of Naples, which formed the third. At present, it is divided into the following independent states, which are not connected with each other by any political tie, and of which an account will be given under the separate heads—1. the kingdom of Sardinia; 2. Lombardy, or Austrian Italy (including Milan and Venice); 3. the duchy of Parma; 4. the duchy of Modena (including Massa); 5. the grand-duchy of Tuscany; 6. the duchy of Lucca; 7. the republic of San Marino; 8. the papal dominions (see *Church, States of the*); 9. the kingdom of Naples or the Two Sicilies. *Italia* did not become the general name of this country until the age of Augustus. It had been early imperfectly known to the Greeks under the name of *Hesperia*. *Ausonia*, *Stæurnia*, and *Enotria* were also names applied by them to the southern part, with which alone they were at first acquainted. The name *Italia* was a

\* Savoy is not included here, not being considered a part of Italy by the *Revue*.

first merely a partial name for the southern extremity, until it was gradually extended to the whole country. It was probably derived from *Italus*, an Etrurian chief, though others give a different etymology. (See, in Niebuhr's *Roman History*, *Ancient Italy*.) Ancient Italy is generally described under the thirteen following heads:—1. Liguria (see *Gaul*); 2. Gallia Cisalpina; 3. Venetia; 4. Etruria; 5. Umbria and Picenum; 6. the Sabini, Æqui, Marsi, Peligni, Vestini, Marrucini; 7. Rome; 8. Latium; 9. Campania; 10. Samnium; 11. Apulia; 12. Lucania; 13. the Brutii. The ancient geography of Italy has been learnedly illustrated by Mannert (*Leipsic*, 1823, 2 vols.) and Cramer (*Description of Ancient Italy*, 2 vols., Oxford, 1826). The modern history of Italy begins with the fall of the Western Empire.

*First Period, from Odoacer (476) to Alboin (568)*, comprises the time of the dominion of the Herulians and Rugians, and of the Ostrogothic kingdom. Romulus was the founder of the city, that became the mistress of the world; Augustus founded its universal monarchy, and Romulus Augustus was the name of its last feeble emperor, who was dethroned by his German guards. Odoacer, their leader, assumed the title of *king of Italy*, and thus this country was separated from the Roman empire. But this valiant barbarian could not communicate a spirit of independence and energy to the degenerate Italians; nothing but an amalgamation with a people in a state of nature could effect their regeneration. Such a people already stood on the frontiers of Italy. Theodoric (q. v.), king of the Ostrogoths, instigated by Zeno, emperor of the East, overthrew (493) the kingdom of Odoacer, and reduced all Italy. His Goths spread from the Alps to Sicily. In the lagoons of the Adriatic alone, some fugitives, who had fled from the devastations of Attila, and obtained a subsistence as sailors, and by the manufacture of salt, maintained their freedom. Theodoric, who combined the vigour of the north with the cultivation of the south, is justly termed the *Great*, and, under the name of *Dietrich of Bern* (Verona), has become one of the principal heroes of old German story. But the energy of his people soon yielded to Roman corruption. Totila, for ten years, contested in vain the almost completed conquest with the military skill of Belisarius. He fell in battle in 552, and Teias in 553, after which Italy was annexed to the Eastern Empire, under an exarch, who resided at Ravenna. But the first exarch, Narces, a eunuch, sunk under the intrigues of the Byzantine court, and his successor neglected the defence of the passes of the Alps. The country was then invaded by the Lombards, a German people which had emigrated from the Elbe to Pannonia. Under king Alboin, they conquered Lombardy, which received its name from them, almost without a blow. Their government was less favourable to the arts and sciences than that of the Goths.

*Second Period.—From Alboin to Charlemagne (774), or Period of the Lombard Empire.* The kingdom of the Lombards included Upper Italy, Tuscany and Umbria. Alboin also created the duchy of Benevento, in Lower Italy, with which he invested Zotto. The whole of Lombardian Italy, was divided into thirty great fiefs, under dukes, counts, &c., which soon became hereditary. Together with the new kingdom, the confederation of the fugitives in the lagoons still subsisted in undisturbed freedom. The islanders, by the election of their first doge, Anafesto, in 697, established a central government; and the republic of Venice was founded. (See *Venice*.) Ravenna, the seat of the exarch, with Romagna, the Pentapolis, or the five maritime cities (Rimini, Fano, Pesaro, Sinigaglia, and Ancona), and almost all the coasts of Lower Italy, where Amalfi

and Gaeta had dukes of their own, of the Greek nation, remained unconquered, together with Sicily and the capital, Rome, which was governed by a patrician in the name of the emperor. The slight dependence on the court of Byzantium disappeared almost entirely in the beginning of the eighth century, when Leo the Isaurian exasperated the orthodox Italians, by his attack on images. (See *Iconoclasts*.) The cities expelled his officers, and chose consuls and a senate, as in ancient times. Rome acknowledged, not indeed the power, but a certain paternal authority of its bishops, even in secular affairs, in consequence of the respect which their holiness procured them. The popes, in their efforts to defend the freedom of Rome against the Lombards, forsaken by the court of Byzantium, generally had recourse to the Frankish kings. In consideration of the aid expected against king Astolphus, pope Stephen III. (753) not only anointed Pepin, who had been made king of the Franks, in 752, with the approbation of pope Zacharias, but, with the assent of the municipality of Rome, appointed him patrician, as the imperial governor had hitherto been denominated. Charlemagne made war upon Desiderius, the king of the Lombards, in defence of the Roman church, took him prisoner in his capital, Pavia, united his empire with the Frankish monarchy (774), and eventually gave Italy a king in his son Pepin. But his attempts against the duchy of Benevento, the independence of which was maintained by duke Arichis, and against the republics in Lower Italy, where Naples, Amalfi, and Gaeta in particular, had become rich by navigation and commerce, were unsuccessful. The exarchate, with the five cities, had already been presented to the pope by Pepin, in 756, and Charlemagne confirmed the gift, but the secular supremacy of the popes was first completed by Innocent III., about 1200.

*Third Period.—From Charlemagne to Otto the Great (961), or Period of the Carolingians and Interregnum.* Leo III. bestowed on the king of the Franks, on Christmas day, A. D. 800, the imperial crown of the West, which needed a Charlemagne to raise it from nothing. But dislike to the Franks, whose conquest was looked upon as a new invasion of barbarians, united the free cities, Rome excepted, more closely to the Eastern Empire. Even during the lifetime of Charlemagne, Frankish Italy was given to his grandson Bernard (810). But, Bernard having attempted to become independent of his uncle, Louis the Debonnaire, he was deprived of the crown, and his eyes were torn out. Italy now remained a constituent part of the Frankish monarchy, till the partition of Verdun (843), when it was allotted, with the imperial dignity, and what was afterwards called *Lorraine*, to Lothaire I., eldest son of Louis. Lothaire left the government (850), to his son Louis II., the most estimable of the Italian princes of the Carolingian line. After his death (875), Italy became the apple of discord to the whole family. Charles the Bald of France first took possession of it, and, after his death (877), Carloman, king of Bavaria, who was succeeded, in 880, by his brother Charles the Fat, king of Suabia, who united the whole Frankish monarchy for the last time. His dethronement (887) was the epoch of anarchy and civil war in Italy. Berengarius, duke of Friuli, and Guido, duke of Spoleto (besides the marquises of Ivrea, the only ones remaining of the thirty great vassals), disputed the crown between them. Guido was crowned king and emperor, and, after his death (894), his son Lambert. Arnold, the Carolingian king of the Germans, enforced his claims to the royal and imperial crown of Italy (896), but, like most of his successors, was able to maintain them only during his

residence in the country. After the death of Lambert and Arnold (898 and 899), Louis, king of Lower Burgundy, became the competitor of Berengarius I.; and this bold and noble prince, although crowned king in 894, and emperor in 915, did not enjoy quiet till he had expelled the emperor Louis III. (905), and vanquished another competitor, Rodolph of Upper Burgundy: he was even then unable, on account of the feeble condition of the state, to defend the kingdom effectively against the invasions of the Saracens (from 890) and the Hungarians (from 899). After the assassination of Berengarius (924), Rodolph II. relinquished his claims to Hugh, count of Provence, in exchange for that country. Hugh sought to strengthen the insecure throne of Italy by a bloody tyranny. His nephew, Berengarius, marquis of Ivrea, fled from his snares to Otho the Great of Germany (940), assembled an army of fugitives, returned, and overthrew Hugh (945), who was succeeded by his son Lothaire. Berengarius became his first counsellor. But, after the death of Lothaire, in 950 (poisoned, it was said, by Berengarius), the latter wished to compel his widow—the beautiful Adelaide—contrary to her inclination, to marry his son. Escaping from his cruelty and her prison, she took refuge in the castle of Canossa, where she was besieged by Berengarius II. She now applied for aid to Otho I., king of Germany, who passed the Alps, liberated her, conquered Pavia, became king of the Franks and Lombards (in 951), and married Adelaide. To a prompt submission, and the cession of Friuli, the key of Italy, which Otho gave to his brother Henry, Berengarius was indebted for permission to reign as the vassal of Otho. But, the nobles of Italy preferring new complaints against him, ten years after, Otho returned (961), deposed him, and led him prisoner to Bamberg and, after having been himself crowned king of Italy with the iron crown, in 961, united this kingdom with the German. Otho gave the great imperial fiefs to Germans, and granted to the Italian cities privileges that were the foundation of a free constitution, for which they soon became ripe. The growing wealth of the papal court, owing to the munificence of the French kings, which had promoted their influence on the government, so beneficial under Leo IV., and popes of a similar character, became, through the corruption of the Roman court, in the tenth century, the first cause of its decline. The clergy and the people elected the popes according to the will of the consuls and a few patricians. In the first half of the tenth century, two women disposed of the holy chair. Theodora elevated (914) her lover John X., and Marozia, the daughter of Theodora, elevated her son, John XI., to the papal dignity. The brother of the latter, Alberic of Camerino, and his son Octavian, were absolute masters of Rome, and the last was pope, under the name of John XII., when twenty years of age (956). Otho the Great, whom he had crowned emperor in Rome, in 962, deposed him, and chose Leo VIII. in his stead; but the people, jealous of its right of election, chose Benedict V. From this time, the popes, instead of ruling the people of Rome, became dependent on them. In lower Italy, the republics of Naples, Gaeta, and Amalfi still defended their independence against the Lombard duchy of Benevento, with the more ease, since the duchy had been divided (839) between Siconolfus of Salerno and Radelghisius of Benevento, and subsequently among a greater number, and since with the dukes they had had a common enemy in the Saracens, who had been previously invited over from Sicily by both parties (about 830), as auxiliaries against each other, but who had settled and maintained themselves in Apulia. The emperors Louis II. and Basilus Macedo had, with combined forces,

broken the power of the Mussulmans (866); the former was, nevertheless, unable to maintain himself in Lower Italy, but the Greeks, on the contrary, gained a firmer footing, and formed, of the regions taken from the Saracens, a separate province, called the *Thema of Lombardy*, which continued under their dominion, though without prejudice to the liberty of the republics, upwards of a hundred years, being governed by a catapan (governor-general) at Bari. Otho the Great himself did not succeed in driving them altogether from Italy. The marriage of his son, Otho II., with the Greek princess Theophanu, put an end to his exertions for this purpose, as did the unfortunate battle at Basenteio to the similar attempts renewed by Otho II. (980).

*Fourth Period—From Otho the Great to Gregory VII. (1073). The Dominion of the German Kings.* In opposition to the designs of the count of Tusculum, who wished to supplant the absent emperor at Rome, a noble Roman, the consul Crescentius, attempted to govern Rome under the semblance of her ancient liberty (980). Otho II., king since 973, occupied with his projects of conquest in Lower Italy, did not interfere with this administration, which became formidable to the vicious popes Boniface VII. and John XV. But, when Otho III., who had reigned in Germany since 983, raised his kinsman Gregory V. to the papedom, Crescentius caused the latter to be expelled, and John XVI., a Greek, to be elected by the people. He also endeavoured to place Rome again under the nominal supremacy of the Byzantine empire. Otho, however, reinstated Gregory, besieged Crescentius in the castle of St Angelo, took him prisoner, and caused him to be beheaded with twelve other noble Romans (998). But the Romans again threw off their allegiance to the emperor, and yielded only to force. On the death of Otho III. (1002), the Italians considered their connexion with the German empire as dissolved. Harduin, marquis of Ivrea, was elected king, and crowned at Pavia. This was a sufficient motive for Milan, the enemy of Pavia, to declare for Henry II. (in Italy, I.) of Germany. A civil war ensued, in which every city, relying on its walls, took a greater or less part. Henry was chosen king of Italy, by the nobles assembled in Pavia; but disturbances arose, in which a part of the city was destroyed by fire (A.D. 1004). Not till after Harduin's death (1015) was Henry recognised as king by all Lombardy; he was succeeded by Conrad II. (in Italy I.) At a diet held at Roncaglia, near Piacenza, in 1037, Conrad made the fiefs hereditary by a fundamental law of the empire, and endeavoured to give stability and tranquillity to the state, but without success. The cities (which were daily becoming more powerful) and the bishops were engaged in continual quarrels with the nobility, and the nobility with their vassals which could not be repressed. Republican Rome, under the influence of the family of Crescentius, could be reduced to obedience neither by Henry II. and Conrad II. nor by the popes. When Henry III. (in Italy, II.), the son and successor of Conrad (1039), entered Italy (1040), he found three popes in Rome, all of whom he deposed, appointed in their stead Clement II., and ever after filled the papal chair by his own authority, with virtuous German ecclesiastics. This reform gave the popes new consequence, which afterwards became fatal to his successor. Henry died in 1056. During the long minority of his son Henry IV. (in Italy, III.), the policy of the popes, directed by the monk Hildebrand (afterwards Gregory VII.), succeeded in creating an opposition, which soon became formidable to the secular power (See *Pope*). The Normans also contributed to the result. As early as 1016, warriors from Normandy

had established themselves in Calabria and Apulia. Allies sometimes of the Lombards, sometimes of the republics, sometimes of the Greeks against each other and against the Saracens, they constantly became more powerful by petty wars. The great preparations of Leo IX. for their expulsion terminated in his defeat and capture (1053). On the other hand, Nicolas II. united with the Norman princes, and, in 1059, invested Robert Guiscard with all the territories conquered by him in Lower Italy. From that time, the pope, in his conflicts with the imperial power, relied on the support of his faithful vassal, the duke of Apulia and Calabria, to which Sicily was soon added. While the small states of the south were thus united into one large one, the kingdom in the north was dissolving into smaller states. The Lombard cities were laying the foundation of their future importance. Venice, Genoa and Pisa were already powerful. The Pisanese, who, in 980, had given to Otto II. efficient aid against the Greeks in Lower Italy, and, in 1005, boldly attacked the Saracens there, ventured, in connexion with the Genoese (no less warlike and skilled in navigation), to assail the infidels in their own territory, and twice conquered Saracenia (1017 and 1050), which they divided into several large fiefs, and distributed them among their principal citizens.

*Fifth Period.—From Gregory VII. to the Fall of the Hohenstaufen. Struggles of the Popes and Republics with the Emperors.* Gregory VII. humbled Henry IV. in 1077. Urban II. instigated the emperor's own sons against their father. Conrad, the eldest, was crowned king of Italy in 1093, after whose death (1101) Henry, the second son, succeeded in deposing his father from the imperial throne. Henry V., the creature of the pope, soon became his opponent; but, after a severe conflict, concluded with him the concordate of Worms (1122). A main point, which remained unsettled, gave rise to new difficulties in the twelfth and thirteenth centuries—the estate of Matilda, marchioness of Tuscany, who (died 1115), by a will, the validity of which was disputed by the emperor, bequeathed all her property to the papal see. Meanwhile, in the south, the Norman state (1130), under Roger I., was formed into a kingdom, from the ruins of republican liberty and of the Greek and Lombard dominion. (See *Sicilies, the Two*.) In the small republics of the north of Italy, the government was, in most cases, divided between the consuls, the lesser council (*credenza*), the great council, and the popular assembly (*parlamento*). Petty feuds developed their youthful energies. Such were those that terminated with the destruction of Lodi by Milan (1111), and the ten years' siege of Como by the forces of all the Lombard cities (1118—1128). The subjugation of this city rendered Milan the first power in Lombardy, and most of the neighbouring cities were her allies. Others formed a counter alliance with her antagonist, Pavia. Disputes between Milan and Cremona were the occasion of the first war between the two unions (1129), to which the contest of Lothaire II. and Conrad of Hohenstaufen for the crown, soon gave another direction. This was the origin of the Ghibelines (favourites of the emperor) and the Guelfs (the adherents of the family of Guelfs (q. v.), and, in general, the party of the popes). In Rome, the love of liberty, restrained by Gregory VII., rose in proportion as his successors ruled with less energy. The animosity between Gelasius II. and Gregory VIII., Innocent II. and Anacletus II., renewed the hopes of the Romans. Arnold of Brescia, formerly proscribed (1139) for his violent attacks against the luxury of the clergy in that country, was their leader (1146). After eight years, Adrian IV succeeded in effecting

his execution. Frederic I. of Hohenstaufen (called *Barbarossa*) crossed the Alps six times, in order to defend his possessions in Italy against the republicanism of the Lombard cities. Embracing the cause of Pavia as the weaker, he devastated (1154) the territory of Milan, destroyed Tortona, and was crowned in Pavia and Rome. In 1158, he reduced Milan, demolished the fortifications of Piacenza, and held a diet at Roncaglia, where he extended the imperial prerogatives conformably with the Justinian code, gave the cities chief magistrates (*podestà*), and proclaimed a general peace. His rigour having excited a new rebellion, he reduced Crema to ashes (1160), compelled Milan to submission, and, having driven out all the inhabitants, demolished the fortifications (1162). Nothing, however, but the terror of his arms upheld his power. When the emperor entered Italy (1163) without an army, the cities concluded a union for maintaining their freedom, which in 1167, was converted into the Lombard confederacy. The confederates restored Milan, and, to hold in check the Ghibeline city of Pavia, built a new city, called, in honour of the pope, *Alessandria*. Neither Frederic's governor, Christian, archbishop of Mentz, nor he himself, could effect any thing against the confederacy; the former failed before Ancona (1174), with all the power of Ghibeline Tuscany; and the latter, with the Germans, before Alessandria (1175). He was also defeated by Milan, at Legnano in 1176. He then concluded a concordate with Alexander III., and a truce with the cities (1176), at Venice, and a peace, which secured their independence, at Constance (1183). The republics retained the *podestà* (foreign noblemen, now elected by themselves) as judges and generals. As formerly, all were to take the oath of fealty and allegiance to the emperor. But, instead of strengthening their league into a permanent confederacy (the only safety for Italy), they were soon split into new factions, when the designs of the Hohenstaufen on the throne of Sicily drew Frederic and Henry VI. (V) from Lombardy. The defeat of the united forces of almost all Lombardy, on the Oglio, by the inhabitants of Brescia, though inferior in numbers, is celebrated under the name of *La mala morte* (1197). Among the nobles, the Da Romano were the chiefs of the Ghibelines, and the marquises of Este of the Guelfs. During the minority of Frederic II., and the disputes for the succession to the German throne, Innocent III. (Frederic's guardian) succeeded in re-establishing the secular authority of the holy see in Rome and the surrounding country, and in enforcing its claims to the donations of Charlemagne and Matilda. He also brought over almost all Tuscany, except Pisa, to the party of the Guelfs (1197). A blind hereditary hatred, rather than a zeal for the cause, inspired the parties; for when a Guelf (Otto IV.) ascended the imperial throne, the Guelfs became his party, and the Ghibelines the pope's; but the reversion of the imperial crown to the house of Hohenstaufen, in the person of Frederic II., soon restored the ancient relations (1212). In Florence, this party spirit gave pretence and aliment (1215) to the disputes of the Buondelmonti and Donati with the Uberti and Amidei, originating in private causes; and most cities were thus internally divided into Guelfs and Ghibelines. The Guelf cities of Lombardy renewed the Lombard confederacy, in 1226. The Dominican, John of Vicenza, attacked these civil wars. The assembly at Paquara (1233) seemed to crown his exertions with success; but his attempt to obtain secular power in Vicenza occasioned his fall. After the emperor had returned from his crusade (1230), he waged war, with varying success, against the cities and against Gregory IX, heedless of the excommunication, while

Eselin da Romano, under the pretence of favouring the Ghibelines, established, by every kind of violence, his own power in Padua, Verona, Vicenza, and the neighbourhood. The papal court succeeded in seducing the Pisanese family of the Visconti of Gallura in Sardinia, from the republic, and rendering them its vassals, notwithstanding the resistance of the republic, and especially of the counts of Gherardesca. Thence Pisa, too, was divided into Ghibelines (Conti) and Guelfs (Visconti). Frederic, however, married his natural son, Ensius, to a Visconti, and gave him the title of *king of Sardinia*. The plan of Gregory IX., to depose Frederic, was successfully executed by Innocent IV., in the council of Lyons (1245). This completely weakened the Ghibeline party, which was already nearly undermined by the intrigues of the mendicant orders. The faithful Parma revolted; the triumph of the Ghibelines in Florence (1248) lasted only two years; and their second victory, after the battle of Monte Aperto (1260), gave them the ascendancy but six years. The Bolognese united all the cities of Italy in a Guelf league, and, in the battle of the Panaro (1249), took Ensius prisoner, whom they never released. In the Trevisan Mark alone, the Ghibelines possessed the supremacy, by means of Eselin, till he fell before a crusade of all the Guelfs against him (1255). But these contests were fatal to liberty; the house Della Scala followed that of Romano in the dominion, and Milan itself, with a great part of Lombardy, found masters in the house Della Torre. Tyrants every where arose; the maritime republics and the republic of Tuscany alone remained free.

*Sixth Period.—From the Fall of the Hohenstaufen to the Formation of the modern States.* In this period, different princes attempted to usurp the sovereignty of Italy.—1. *The Princes of Anjou.* After Charles I. of Anjou had become, by the favour of the pope, king of Naples, senator of Rome, papal vicar in Tuscany, and had directed his ambition to the throne of Italy (a policy in which his successors persevered), the names of *Guelfs* and *Ghibelines* acquired a new signification. The former denoted the friends, the latter the enemies, of the French. To these factions were added, in the republics, the parties of the nobility and the people, the latter of which was almost universally victorious. The honest exertions of the noble Gregory X. (who died 1276) to establish peace, were of no avail; those of Nicolas III., who feared the preponderance of Charles, were more efficient; but Martin IV. (1280), servilely devoted to Charles, destroyed every thing which had been effected, and persecuted the Ghibelines with new animosity. A different interest—that of trade and navigation—impelled the maritime republics to mutual wars. The Genoese assisted Michael Palæologus (1261) to recover Constantinople from the Venetians, and received in return Chios; at Meloria, they annihilated (1284) the navy of the Pisans, and completed their dominion of the sea by a victory over the Venetians at Curzola (1298). Florence rendered its democracy complete by the banishment of all the nobles (1282), and strengthened the Guelf party by wise measures; but a new schism, caused by the insignificant Pistoia, soon divided the Guelfs in Florence and all Tuscany into two factions—the Neri (Black) and Bianchi (White) (1300). The latter were almost all expelled by the intrigues of Boniface VIII., and joined the Ghibelines (1302). In Lombardy, freedom seemed to have expired, when the people, weary of the everlasting feuds of their tyrants, rose in most of the cities, and expelled them (1302—6), including the Visconti, who had supplanted the Della Torre (1277) in the government of Milan.—2. *The Germans and the*

*Della Scala.* Henry VII., the last emperor who had appeared in Italy for sixty years (1310), restored the princes to their cities, and forced general submission to his requisitions, peace among the parties, and homage to the empire. Florence alone undertook the glorious part which she so nobly sustained for two centuries, as the guardian of Italian freedom, chose Robert of Naples, the enemy of Henry, her protector for five years, and remained free while Italy swarmed with tyrants. The Ghibeline Pisa received a master after the death of Henry, in Uguccione della Fagginola (1314). After his expulsion, Lucca, which he also ruled, received another lord in Castruccio Castracani (1316); Padua fell (1314) to the house of Carrara; Alexandria, Tortona, (1315) and Cremona, (1322) to the Visconti of Milan; Mantua (governed, since 1275, by the Bonaccontis, devolved, by inheritance, to the Gonzagas (1328); in Ferrara, the long-contested dominion of the Este was established (1317); and Ravenna was governed, from 1273, by the Polenta. In the other cities, the same tyranny existed, but frequently changing from family to family, and therefore more oppressive. These petty princes, especially Della Scala, Matteo Visconti, and Castruccio, were a counterpoise to the ambitious wars of Robert of Naples, appointed by Clement V. imperial vicar in Italy. Robert, however, acquired for his son, Charles of Calabria, the government of Florence and Sienna, which he retained till his death (1328). Louis of Bavaria, who came to Italy (1330) to reduce the Anjous and the Guelfs, became himself at variance with the Ghibelines whom he alienated by his caprice and perfidy; and the character of John XXII. so cooled the zeal of the Guelfs, that both parties, recognising the common interest of liberty, became somewhat more friendly. The amiable adventurer John, king of Bohemia, suddenly entered Italy (1330). Invited by the inhabitants of Bologna, favoured by the pope, elected lord of Lucca, every where acting the part of a mediator and peacemaker, he would have succeeded in establishing the peace at which he aimed, had he not been opposed by the Florentines. On his second expedition to Italy (1333), Azzo Visconti, Mastino della Scala, and Robert of Naples, united against him and his army, the papal legate Bertrand of Poitiers, who aspired to the dominion of Bologna. After the downfall of both (1334), when the Pepoli began to rule in Bologna, Mastino della Scala, master of half Lombardy and of Lucca, began to menace the freedom of Lombardy. Florence led the opposition against him, and caused a war of the league, in which it gained nothing but the security of its liberty. After the baffled Mastino had sold Lucca to the Florentines, the Pisans arose, and conquered it for themselves (1342). In Rome, torn by aristocrats, Cola Rienzi (1347) sought to restore order and tranquillity; he was appointed tribune of the people, but was forced after seven months, to yield to the nobility. Having returned, after seven years of banishment, with the legate cardinal Albornoz (1354), he ruled again a short time, when he was murdered in an insurrection. The Genoese, tired of the perpetual disputes of the Ghibeline Spinolas and Dorias with the Guelf Grimaldi and Fieschi, banished all these families in 1339, and made Simon Boccanegra their first doge. In Pisa, the Ghibelines, the council of the captain-general, Ricciani della Gherardesca, separated into two new parties, Barguini and Raspanti, of whom the former under Andrea Gambacorti, expelled the latter (1348). About the time, Italy suffered by a terrible famine (1347) and a still more terrible pestilence (1348), which swept away two thirds of the population. No less terrible was the scourge of the *bande* (banditti), or large companies of soldiers, who, after every peace, re-

turned the war on their own account, ravaging the whole country with fire and sword; such as the bands of the count of Werner (1348) and of Montreal (1354).—3. *The Visconti.* John Visconti, archbishop and lord of Milan, and his successors, were checked in their dangerous projects for extending their power, not so much by Charles IV.'s expedition through Italy, and by the exertions of innumerable papal legates, as by the wisdom and intrepidity of the republics, especially of the Florentine. Charles appeared in 1355, overthrew in Pisa the Gambacorti, elevating the Raspanti, destroyed in Sienna the dominion of the Nine, to which succeeded that of the Twelve, subjected for the moment all Tuscany, and compelled Florence itself to purchase the title of an imperial city. In 1363, he effected but little against the Visconti, freed Lucca from the Pisanese power, and overthrew the Twelve in Sienna; but his attacks on the liberty of Pisa and Sienna failed in consequence of the valour of the citizens. Pope Innocent VI. succeeded in conquering the whole of the States of the Church by means of the cardinal legate Egidius Albornoz (1354—60); but, reduced to extremities, by the oppressions of the legates, and encouraged by Florence, the enemy of all tyranny, the conquered cities revolted in 1375. The cruelties of cardinal Robert of Geneva (afterwards Clement VII.), and of his band of soldiers from Bretagne, produced only a partial subjugation; and in the great schism, the freedom of these cities, or rather the power of their petty tyrants, was fully confirmed. The Visconti, meanwhile, persisting in their schemes of conquest, arrayed the whole strength of Italy in opposition to them, and caused the old factions of Guelphs and Ghibelines to be forgotten in the impending danger. Genoa submitted to John Visconti (1353), who had purchased Bologna from the Pepoli (1350); but his enterprise against Tuscany failed through the resistance of the confederated Tuscan republics. Another league against him was concluded by the Venetians (1354) with the petty tyrants of Lombardy. But the union of the Florentines with the Visconti against the papal legates (1375) continued but a short time. In Florence, the Guelphs were divided into the parties of the Ricci and the Albizzi. The sedition of the Ciompi (1378), to which this gave rise, was quelled by Michael di Lando, who had been elected gonfaloniere by themselves, in a way no less manly than disinterested. The Venetians, irritated with Carrara on account of the assistance he had given the Genoese in the war at Chioma (1379), looked quietly on while John Galeazzo Visconti deprived the Della Scala and Carrara of all their possessions (1387 and 1388), and Florence alone assisted the unfortunate princes. Francis Carrara made himself again master of Padua (1390), and maintained his advantages, till he sunk under the enmity of the Venetians (1406), who, changing their policy, became henceforth, instead of the opponents, the rivals of the ambitious views of the Visconti.—John Galeazzo obtained from the emperor Wenceslaus the investiture of Milan as a duchy (1395), purchased Pisa (which his natural son Gabriel bargained away to Florence, 1406) from the tyrant Gerard of Appiano (who reserved only the principality of Piombino), and subjugated Sienna (1399), Perugia (1400) and Bologna (1402), so that Florence, fearfully menaced, alone stood against him in the cause of liberty. On his death (1402), the prospect brightened, and during the minority of his son, a great portion of his states was lost. When Ladislaus of Naples, taking advantage of the schism, made himself master of all the Ecclesiastical States, and threatened to conquer all Italy (1409), Florence again alone dared to resist him. But this danger was transitory; the Visconti soon rose up again in

opposition. Duke Philip Maria reconquered all his states of Lombardy, by means of the great Carmagnola (1416—20). Genoa, also, which was sometimes given up, in nominal freedom, to stormy factions (of the Fregosi, Adorni, Montalto, Guarco), and at other times was subject to France (1396), or to the marquis of Montferrat (1411), submitted to him (1421). Florence subsequently entered into an alliance against him with the Venetians (1425); and by means of Carmagnola, who had now come over to them, they conquered the whole country as far as the Adda, and retained it in the peace of Ferrara (1428). In Perugia, the great condottiere Braccio da Montone, of the party of the Baglioni, succeeded in becoming master of this city and of all Umbria, and, for a period, even of Rome (1416). In Sienna, the Petrucci attained a permanent dominion (1430).—4. *Balance of the Italian States.* After Milan had been enfeebled by the Venetians and Florentines, and while Alphonso of Arragon was constantly disturbed in Naples (see *Naples*) by the Anjou party, no dangerous predominance of power existed in Italy, though mutual jealousy still excited frequent wars, in which two parties among the Italian mercenary soldiers, the Bracheschi (from Braccio da Montone) and the Sforzeschi (so called from Sforza Attendolo), continued always hostile to each other, contrary to the custom of those mercenary bands. After the extinction of the Visconti (1447), Francis Sforza succeeded in gaining possession of the Milanese state (1450). (See *Milan*.) The Venetians, who aimed at territorial aggrandizement, having formed a connexion with some princes against him, he found an ally in Florence, which, with a change of circumstances, wisely altered her policy. About this time, the family of the Medici attained to power in that city by their wealth and talent. (See *Medici*.) Milan (where the Sforza had established themselves), Venice (which possessed half of Lombardy), Florence (wisely managed by Lorenzo Medici), the States of the Church (for the most part restored to the holy see), and Naples (which was incapable of employing its forces in direct attacks on other states), constituted, in the fifteenth century, the political balance of Italy, which, during the manifold feuds of these states, permitted no one to become dangerous to the independence of the rest, till 1494, when Charles VIII. of France entered Italy to conquer Naples, and Louis Moro Sforza played the part first of his ally, then of his enemy, while the pope, Alexander VI. eagerly sought the friendship of the French, to promote the exaltation of his son, Cæsar Borgia.—5. *Content of foreign Powers for Provinces in Italy.* Charles VIII. was compelled to evacuate Naples and all Italy; his successor, Louis XII. was also expelled, by Ferdinand the Catholic, from Naples (conquered in 1504). He was more successful against Milan, which, supported by hereditary claims, he subjected to himself in 1500. Cæsar Borgia's attempts to acquire the sovereignty of Italy were frustrated by the death of his father (1505); when the warlike pope, Julius II. completed the subjugation of the States of the Church, not, indeed, for a son or nephew, but in the name of the holy see. He concluded with Maximilian I. Ferdinand the Catholic, and Louis XII. the league of Cambray (1508) against the ambitious policy of the Venetians, who artfully succeeded in dissolving the league, which threatened them with destruction. The pope then formed a league with the Venetians themselves, Spain, and the Swiss, for the purpose of driving the French from Italy. This holy league (1509) did not, however, then attain its object, although Julius was little affected by the French and German council held at Pisa to depose him.

Max. Sforza, who had reacquired Milan (1512), relinquished it without reserve to Francis I. (1515); but the emperor Charles V. assumed it as a reverted fief of the empire, and conferred it on Francesco Sforza, brother of Maximilian (1520.) This was the cause of violent wars, in which the efforts of Francis were always unsuccessful. He was taken prisoner at Pavia (1525), and, with his other claims, was compelled to renounce those on Milan, which remained to Sforza, and, after his death (1540), was granted by Charles V. to his son Philip. The Medicean popes, Leo X. (1513) and Clement VII. (1523), were bent, for the most part, on the aggrandisement of their family. Charles V. to whom all Italy submitted after the battle of Pavia, frustrated indeed the attempts of Clement VII. to weaken his power, and conquered and pillaged Rome (1527); but, being reconciled with the pope, he raised (1530) the Medici to princely authority. Florence, incensed at the foolish conduct of Pietro towards France, had banished the Medici in 1494, but recalled them in 1512, and was now compelled to take a station among the principalities, under duke Alexander I. de' Medici. Italian policy, of which Florence had hitherto been the soul, from this period, is destitute of a common spirit, and the history of Italy is therefore destitute of a central point.

*Seventh period.—Mutations of the Italian States down to the French Revolution.* After the extinction of the male branch of the marquises of Montferrat, Charles V. gave this country to the Gonzaga of Mantua (1536). Maximilian II., subsequently (1573) raised Montferrat to a duchy. The Florentines failed (1537) in a new attempt to emancipate themselves, after the murder of duke Alexander. Cosmo I. succeeded him in the government, by the influence of Charles V. Parma and Piacenza, which Julius II. had conquered for the papal see, Paul III. erected into a duchy (1545), which he gave to his natural son, Peter Alois Farnese, whose son Ottavio obtained the imperial investiture in 1556. Genoa (see *Genoa*), subject to the French since 1499, found a deliverer in Andrew Doria (1528). He founded the aristocracy, and the conspiracy of Fiesco (1547) failed to subvert him. In 1553, besides Milan, Charles V. conferred Naples also on his son Philip II. By the peace of Chateau-Cambresis (1559), Philip II. and Henry II. of France, renounced all their claims to Piedmont, which was restored to its rightful sovereign, duke Emanuel Philibert of Savoy, the brave Spanish general. The legitimate male line of the house of Este became extinct in 1597, when the illegitimate Cæsar of Este obtained Modena and Reggio from the empire, and Ferrara was confiscated as a reverted fief by the holy see. In the second half of the sixteenth century, the prosperity of Italy was increased by a long peace, as much as the loss of its commerce allowed,—Henry IV. of France having, by the treaty of Lyons, ceded Saluzzo, the last French possession in Italy, to Savoy. The tranquillity continued till the contest for the succession of Mantua and Montferrat, after the extinction of the Gonzaga family (1627). Misfortunes in Germany compelled Ferdinand II. to confer both countries (1631), as a fief on Charles of Nevers, the protégé of France, whose family remained in possession till the war of Spanish succession. In the peace of Chiasso (1631), Richelieu's diplomacy acquired also Pignerol and Casale—strong points of support, in case of new invasions of Italy, though he had to relinquish the latter (1637). By the extinction of the house Della Rovere, the duchy of Urbino, with which Julius II. had invested it, devolved, in 1631, to the papal see. In the second half of the seventeenth century, the peace of Italy was not interrupted, ex-

cepting by the attempts of Louis XIV. on Savoy and Piedmont, and appeared to be secured for a long time, by the treaty of neutrality at Turin (1696), when the war of Spanish succession broke out. Austria conquered Milan, Mantua, and Montferrat (1706), retained the two first (Mantua was forfeited by the felony of the duke), and gave the latter to Savoy. In the peace of Utrecht (1714), Austria obtained, moreover, Sardinia and Naples; Savoy obtained Sicily, which it exchanged with Austria for Sardinia, from which it assumed the royal title. Mont Genievre was made the boundary between France and Italy. The house of Farnese becoming extinct in 1731, the Spanish Infant Charles obtained Parma and Piacenza. In the war for the Polish throne, of 1733, Charles Emmanuel of Savoy, in alliance with France and Spain, conquered the Milanese territory, and received therefrom, in the peace of Vienna (1738), Novara and Tortona. Charles, Infant of Spain, became king of the two Sicilies, and ceded Parma and Piacenza to Austria. The Medici of Florence, entitled, since 1575, grand-dukes of Tuscany, became extinct in 1737. Francis Stephan, duke of Lorraine, now received Tuscany by the preliminaries of Vienna, and, becoming emperor in 1745, made it the appanage of the younger line of the Austro-Lorraine house. In the war of Austrian succession, the Spaniards conquered Milan (1745), but were expelled thence by Charles Emmanuel, to whom Maria Theresa ceded, in reward, some Milanese districts, viz. all of Vigevanasco and Bobbio, and part of Anghiera and Pavese. Massa and Carrara fell to Modena, in 1743, by right of inheritance. The Spanish Infant, don Philip, conquered Parma and Piacenza in his own name, lost them, and obtained them again as a hereditary duchy, by the peace of Aix-la-Chapelle (1748). Thus, in the eighteenth century, the houses of Lorraine, Bourbon, and Savoy possessed all Italy, with the exception of the ecclesiastical territories, Modena and the republics, which, like a superannuated man, beheld with apathy operations in which they had no share. A quiet of forty years ushered in their downfall.

*Eighth Period.—From the French Revolution to the present Time.*—In September, 1792, the French troops first penetrated into Savoy, and planted the tree of liberty. Though expelled for some time, in 1793, by the Piedmontese and Austrians, they held it at the end of the year. The National Convention had already declared war against Naples, in February, 1793. In April, 1794, the French advanced into the Piedmontese and Genoese territories, but were expelled from Italy in July, 1795, by the Austrians, Sardinians, and Neapolitans. In 1796, Napoleon Bonaparte received the chief command of the French army in Italy. He forced the king of Sardinia to conclude a treaty of peace, by which the latter was obliged to cede Nizza (Nice) and Savoy to France; conquered Austrian Lombardy, with the exception of Mantua; put the duke of Parma and the pope under contribution; and struck such consternation into the king of Naples, that he begged for peace. After Mantua had also fallen, in 1797, Bonaparte forced of Milan, Mantua, the portion of Parma north of the Po, and Modena, the Cisalpine republic. (See *Cisalpine Republic*.) France likewise made war on the pope, and annexed Bologna, Ferrara, and Romagna to the Cisalpine republic (1797), by the peace of Tolentino. The French then advanced towards Rome, overthrew the ecclesiastical government, and erected a Roman republic (1798). In Genoa, Bonaparte occasioned a revolution, by which a democratic republic was formed after the model of the French, under the name of the *Ligurian republic*. The French had, meanwhile, penetrated into Austria, through the

Venetian territory. The Venetians now made common cause with the brave Tyrolese, who gained advantages over the French in their Alps. Bonaparte, therefore, occupied Venice without striking a blow, and gave the republic a democratic constitution; but, by the peace of Campo-Formio (17th Oct., 1797), the Venetian territory, as far as the Adige, was relinquished to Austria, and the rest incorporated with the Cisalpine republic. The king of Sardinia concluded a treaty of alliance and subsidy with France, October 25; but, in 1798, the directory, assailed in Rome from Naples, deemed it expedient to compel him to resign his territories on the main land. Notwithstanding its treaty of amity with France, Naples concluded an alliance, in 1798, with Britain and Russia. The French, therefore, occupied Naples, and erected there the Parthenopean republic. The grand-duke of Tuscany had likewise formed an alliance with Naples and Britain, and his country was, in return, compelled by the French to receive, like Piedmont, a military administration. After the congress of Radstadt (q. v.) was broken off, Austria and the German empire, under Russian support, renewed the war against the French, who again left Naples and Rome to the British, Russians, and Turks. The king and the pope returned to their capitals in Lombardy; the French were defeated by the Austrians, under Kray and Melas, and by the Russians, under Suwarroff, and lost all their fortresses, except Genoa, where Massena sustained a vigorous siege, while his countrymen had to evacuate all Italy. But, in the mean while, Bonaparte was made first consul after his return from Egypt. (See *Egypt, Campaign of the French in.*) He marched with a new army to Italy, defeated the Austrians at the memorable battle of Marengo (1800), and compelled them to a capitulation, by which all the Italian fortresses were again evacuated. By the peace of Lunéville (q. v.), Feb. 9, 1801, the possession of Venice was confirmed to Austria, which was to indemnify the duke of Modena, by the cession of Brisgau. The duke of Parma received Tuscany, and afterwards, from Bonaparte, the title of king of Etruria. Parma was united with France. The Cisalpine and Ligurian republics were guaranteed by Austria and France, and with the Ligurian territories were united the imperial fiefs included within their limits. The king of Naples, who had occupied the States of the Church, was obliged to conclude peace at Florence (28th of March). By Russian mediation, he escaped with the cession of Piombino, the *Stato degli Presidj*, and his half of the island of Elba, together with the promise of closing his harbours against the British. The other half of Elba Tuscany had already relinquished to France. But the whole island was obstinately defended by the British and Corsicans, with the armed inhabitants, and not evacuated till autumn. The *Stato degli Presidj* France ceded to Etruria, September 19. Strong detachments of French troops remained both in Naples and Tuscany, and their support cost immense sums. To the republics of Genoa and Lucca the first consul gave new constitutions in 1801. But in January, 1802, the Cisalpine republic was transformed into the Italian republic, in imitation of the new French constitution, and Bonaparte became president. He appointed the citizen Melai d'Ételle vice president. Genoa also received a new constitution, and Girolamo Durando for doge. Piedmont, however, was united with France. After Bonaparte had become emperor, in 1804, he attached (March 17, 1805) the royal crown of Italy to the new imperial crown; he promised, however, never to make the new monarchy with France, and even to give it a king of its own. The new constitution was similar to that of the French empire. Napoleon

founded the order of the iron crown, and having placed the crown on his own head, at Milan, May 26, and Genoa having been united with France, May 25, he appointed his step-son, Eugene Beauharnais, viceroy of Italy, who laboured with great zeal for the improvement of all branches of the government, of industry, and the arts. Circumstances, however, rendered this new government oppressive, as the public expenses, during peace, amounted to 100,000,000 francs, which were all to be contributed by less than 4,000,000 people. No European power recognised, expressly, the Italian kingdom of Napoleon. The emperor continued to strengthen his power against the active enemies of the new order of things, and gave to his sister Elisa the principality of Piombino, and to her husband, Pasquale Bacciocchi, the republic of Lucca, as a principality, both as French fiefs. Parma, Piacenza and Guastalla were incorporated with the French empire, July 21st. The pope was obliged to sanction the imperial coronation by his presence. Austria now acceded to the alliance of Russia, and Britain against France. Naples, also, again suffered the British and Russians to land. But the success of the Austrian arms was frustrated by the defeats at Ulm and Austerlitz, after which the peace of Presburg (December 26th, 1805), completed the French supremacy in Italy. Austrian Venice, with Istria and Dalmatia, was united to the kingdom of Italy; and this, with all the French institutions, Italy recognised. The kingdom had now an extent of 35,450 square miles, with 5,657,000 inhabitants. Naples was evacuated by its auxiliaries, and occupied by the French, notwithstanding the attempts of the queen to excite an universal insurrection. March 31, Napoleon gave the crown of Naples to his brother Joseph. In vain did the prince of Hesse-Philippthal defend the fortress of Gaeta. In vain did an insurrection break out in Calabria, encouraged by the British, who, under general Stuart, defeated the French at Maida, July 4, and conquered several fortified places on the coast; but, after Gaeta had fallen (July 18), and Massena penetrated as far as Calabria, they re-embarked. As the British, however, were masters of the sea, Sicily was secured to king Ferdinand. In 1808, the widow of the king of Etruria, who conducted the regency in behalf of her minor son, was deprived of her kingdom, which was united with France. Napoleon, moreover, appointed his brother-in-law, the prince Borghese, governor-general of the departments beyond the Alps, who took up his residence at Turin. As Napoleon had, meanwhile, given his brother Joseph the crown of Spain (who reluctantly left Naples, where he was much esteemed, as he had, within this short time, laid the foundation of the most essential improvements), he filled the throne of Naples with his brother-in-law, Joachim Murat, until that period grand-duke of Berg, who entered Naples Sept. 6, 1808. In 1809, the emperor gave Tuscany to his sister Elisa, of Piombino, with the title of grand-duchess. In the same year, Austria made new exertions to break the excessive power of France; but Napoleon again drove her troops from the field, and appeared once more victorious in Vienna, where he proclaimed (May 17) the end of the secular authority of the popes (a measure of which his downfall has delayed the execution), and the union of the States of the Church with France. Rome became the second city of the empire, and a pension of 2,000,000 of francs was assigned to the pope. After the peace of Vienna, by which Napoleon acquired the Illyrian provinces, Istria and Dalmatia were separated from the kingdom of Italy, and attached to them. On the other hand, Bavaria ceded to Italy the circle of the

Adige, a part of Eisach, and the jurisdiction of Clausen. The power of the French emperor was now, to all appearance, as firmly established in Italy as in all Europe. While the Italian people were supporting French armies, sacrificing their own troops in the ambitious wars of Napoleon in remote regions, and were obliged to pay heavy taxes in the midst of the total ruin of their commerce, all the periodicals were full of praises of the institutions for the encouragement of science, arts, and industry in Italy. After the fatal retreat from Russia, Murat, whom Napoleon had personally offended, deserted the cause of France, and joined Austria, Jan. 11, 1814, whose army penetrated into Italy, under Bellegarde. The viceroy, Eugene, continued true to Napoleon and his own character, and offered to the enemies of his dynasty the boldest resistance, which was frustrated by the fall of Napoleon in France. After the truce of April 21, 1814, the French troops evacuated all Italy, and most of the provinces were restored to their legitimate sovereigns. The wife of Napoleon, however, the empress Maria Louisa, obtained the duchies of Parma, Piacenza, and Guastalla, with reversion to her son; and Napoleon himself became sovereign of Elba, of which he took possession May 4. But, before the congress of Vienna had organized the political relations of Europe, he effected his return to France, March 1, 1815. At the same time, the king of Naples, Murat (See *Murat*), abandoned his former ambiguous attitude, and took up arms, as he pretended, for the independence of Italy. But his appeal to the Italians, March 30, was answered by a declaration of war by Austria, April 12. Driven from Bologna by the Austrian forces, April 15, and totally defeated by Bianchi Tolentino, May 2 and 3, he lost the kingdom of Naples, into which the Austrian general Nugent had penetrated from Rome, and Bianchi from Aquila, seven weeks after the opening of the campaign. He embarked from Naples, with a view of escaping to France, May 19. Ferdinand IV. returned from Palermo, and Murat's family found an asylum in Austria. Murat himself made a descent in Calabria, from Corsica, in order to recover his lost kingdom. He was taken prisoner at Pizzo, brought before a court-martial, and shot, Oct. 13, 1815.\*

\* If the downfall of Napoleon was regretted in any quarter of the world, it was in Italy. This country, which, to the misfortune of Germany—that of being split into petty divisions, and convulsed by civil dissensions, for centuries—adds the further misfortune of obeying foreign princes, had become destitute of every element of national life. Its commerce was fettered by the numerous political divisions; its administration poisoned and vitiated to a degree of which none can have an idea, except an eye-witness; the cultivators of the ground impoverished by the heavy rents which they had to pay to the rich land-owners; science enervated by the sway of the clergy; the noblemen, distrusted by the foreign governments, where they existed, and not admitted to offices of great importance, had lost energy and activity; in fact, hardly any thing could be said to flourish, with the exception of music, and, to a certain degree, other fine arts. Under Napoleon, every thing was changed. Italian armies were created, which gave birth to a sense of military honour among the people; the organization of the judicial tribunals was improved, and justice much better administered; industry was awakened and encouraged; schools received new attention, and the sciences were concentrated in large and effective learned societies: in short, a new life was awakened, and no Italian or German, who wishes well to his country, can read without deep interest the passage in *Las Cases' Memorial*, in which Napoleon's views on these two countries are given. His prophecy, that Italy will one day be united, we hope will be fulfilled. Union has been the ardent wish of reflecting Italians for centuries, and the want of it is the great cause of the suffering of this beautiful but unfortunate country. A very interesting work, respecting the improvement of civil spirit in Italy, during the time of Napoleon, is *Lettres sur l'Italie*, by

Meanwhile, the congress of Vienna, by the act of June 9, 1815, had arranged the affairs of Italy:—1. The king of Sardinia was reinstated in his territories, according to the boundaries of 1792, with some alterations on the side of Geneva; for the portion of Savoy, left in possession of France by the peace of Paris, of May 30, 1814, was restored by the treaty of Paris, of November 20, 1815. To his states was united Genoa, as a duchy, according to the boundaries of that republic, in 1792, and contrary to the promises made to Genoa.—2. The emperor of Austria united with his hereditary states the new Lombardo-Venetian provinces formerly belonging to Austria, the Valteline, Bormio, and Chiavenna, separated from the Grisons, besides Mantua and Milan. Istria, however, was united with the Germano-Austrian kingdom of Illyria; Dalmatia, with Ragusa and Cattaro, constituting a distinct Austrian kingdom.—3. The valley of the Po was adopted as the boundary between the States of the Church and Parma; otherwise, the boundaries of Jan. 1, 1792, were retained. The Austrian house of Este again received Modena, Reggio, Mirandola, Massa, and Carrara.—4. The empress Maria Louisa received the state of Parma, as a sovereign duchess, but, by the treaty of Paris, of June 10, 1817, only for life, a being agreed that the duchess of Lucca and her descendants should inherit it. Lucca, in that case, falls to the Tuscan dynasty, which, in return, resigns its districts in Bohemia to the duke of Reichstadt.—5. The archduke Ferdinand of Austria became again grand-duke of Tuscany, to which were joined the *Stato degli Presidj*, the former Neapolitan part of the island of Elba, the principality of Piombino, and some small included districts, formerly facts of the German empire. The prince Buoncompagni Ludovisi retained all his rights of property in Elba and Piombino.—6. The Infanta, Maria Louisa, received Lucca, of which she took possession as a sovereign duchy, 1817, with an annuity of 500,000 francs, till the reversion of Parma.—7. The territories of the church were all restored, with the exception of the strip of land on the left bank of the Po; and Austria retained the right of maintaining garrisons in Ferrara and Comacchio.—8. Ferdinand IV. was again recognised as king of the two Sicilies. Britain retained Malta, and was declared the protectress of the United Ionian Islands. (See *Ionian Islands*.) The knights of Malta, who had recovered their possessions in the States of the Church and in the kingdom of the two Sicilies (in Spain, 1815), for a time made Catania, and after 1826, Ferrara, their residence. The republic of San Marino, and the prince of Monaco, whose mountain fortress the Sardinians, and, before them, the French, occupied, alone remained unharmed amid the fifteen political revolutions which Italy had undergone in the course of twenty-five years. The Austrian predominance was thus more firmly established than ever in Italy. In its sea and on its coasts, the British trident rules.

Meanwhile, the desire of union and independence was not extinguished among the people of Italy. Traces of a struggle for a united and liberal government were almost every where visible; and several of the governments, Naples, Rome, and Tera, in particular, in vain endeavoured to protect themselves against secret political societies (*Carbonari*, *Carbonari*) and freemasonry by inquisitorial tribunals, Jesuits and secret police. While the spirit of Carbonarism (see *Carbonari*), excited by the Spanish revolution of January 1, 1820, and having for its

Leillin de Chateaufoux. This work also contains much information respecting the agriculture of Italy, and many other subjects, of which the descriptions of this country hardly ever speak.

object the union of Italy under one government, and its independence of foreign powers, particularly of Austria, threatened to subvert the political institutions of the peninsula in general, and of the single states in particular, and in some places, especially in Naples, Sicily, and Piedmont, actually shook them, by rousing the troops to revolt, and by exciting popular commotions—the cabinets laboured with equal zeal to maintain the principle of stability by the suppression of every revolution, and by opposing to the popular spirit the power of the police. Thus was a question, fraught with the most momentous consequences for all Europe, practically decided in Italy, viz. whether one state is entitled to interfere in the internal affairs of another, and overthrow, by force of arms, any new constitution which militates against the absolute monarchical principle. This principle, which was proclaimed unconditionally by the leading states of the continent, and by Great Britain under the supposition of particular circumstances threatening imminent danger to the neighbouring state (see lord Castlereagh's declaration of the 19th January, 1821), resulted in Austria (as the nearest interested power, which had prevented the introduction of the representative system into Italy in 1815) restoring by force of arms the ancient prerogatives of the royal authority in Naples, Sicily, and Piedmont, after obtaining the assent of the other four leading powers, which had been closely allied since 1818, and also of the Italian sovereigns, who participated, at the congress of Laybach, in the discussions respecting the affairs of Italy. Thus this power not only secured its own Italian provinces from the operation of liberal principles, but established its position as the guardian of the principle of stability and absolute monarchy in Italy. All this was effected by a war of four days with the revolutionary army of the Carbonari of Naples (7th–10th March, 1821), and by a war of three days with the federal party of Piedmont (7th–9th of April, 1821); so that Russia had no occasion to permit its army of 100,000 men, already put in motion, to advance against the Italian nations. For the history of those military revolutions, see *Naples* and *Piedmont*. Respecting the congress of monarchs and ministers held at Troppan, from October to December, 1820; at Laybach, from January to the 13th May, 1821; and the congress, as splendid as it was numerous, held at Verona, from October to the 14th December, 1822, where the question of armed interference in the internal affairs of states, in reference to Italy and Spain, was discussed, and decided against the claims of the popular party, though, in Verona, without the acquiescence of Britain, (see *Congress*, *Interference*, and *Holy Alliance*.) In the congress of Verona the Porte had no share, because it did not recognise the right of interfering in its internal affairs (with reference to the Greeks). Even the deputies of the provisional government of Greece (see *Greece*, *Revolution of*) were not admitted at Verona; the pope, however, opened an asylum to the Greeks in general in Ancona, and suffered the letter of count Metaxa to be published, in which he solicited the mediation of the holy father in behalf of the affairs of Greece at the congress of Verona. The affairs of Italy were discussed in the last sessions of the congress. The plenipotentiaries of the Italian states were as follows, and voted in the following order:—Rome, the cardinal Spina, and Leardi, the nuncio at the court of Vienna (who died 1823); Naples, the prince Alvaro Ruffo, minister of foreign affairs, and the marquis Ruffo, private secretary of king Ferdinand; Sardinia, the count Della Torre, minister of foreign affairs, and the count Pralorne, Sardinian minister to the court of Vienna;

Tuscany, the minister, prince Veri-Corsini; Parma, the count Magarj, minister of state; Lucca, the minister Mausì, and count Guicciardini. The petitions of the Maltese order for their restoration as a sovereign power were submitted by the commander, Antonio Busco; nothing, however, was decided on the subject, and the loan which the order subsequently attempted to negotiate in London, in 1823, had as little success as the negotiation with the Greek senate for the cession of an island. The political maxims which the monarchs followed at these congresses, with respect to Italy, were laid before the world, in the Circular Note of Verona of December 14, 1822. After the dissolution of the congress of Verona, the king of Naples followed the emperor of Austria to Vienna, where he remained till July, 1823, and then returned to his states,—his various oaths taken to support a constitutional form of government having been all violated. The efforts of the most intelligent Italians, from the time of Macchiavelli and Cæsar Borgia, son of Pope Alexander VI. (see *Alexander VI.*), to restore the political unity of their native country, have given rise to the numerous secret political societies in Italy, which in Bologna were called the *Gueffi*; in the Roman and Neapolitan states, the *Patriotti Europei*, and *Carbonari*; to Upper Italy, the *Spilla nera*; in Piedmont and Lombardy, the *Filadelfi* and *Federati*. In Milan, the *Adelfa*, or the *Società de' sublimi maestri perfetti*, laboured to produce a general outbreak of insurrections in Italy, in order to surround the Austrian army on its advance against Naples. Even the advocates of the illiberal system, or the *theocratic faction*, as it was termed, which likewise pursued its objects in secret societies, took advantage of the national desire of greater unity in Italy. It was therefore natural that the idea of connecting the Italian states in a political system, similar to the Germanic confederation, should have been agitated by the statesmen of the congress; but it seems to have been entirely given up, and Italy was left in the hands of Austria. On the other hand, measures were adopted, by all the Italian states, to extirpate the liberal spirit which, propagating itself under a perpetual variety of new forms (for example, in the sect of the *Ordini di Napoli*, of the *Descamisados*, of the *Barabisti*, in Naples and the rest of Italy), had not ceased in the year 1825, in the June of which year a conspiracy was detected at Rome, to pursue its ancient object of uniting all the Italian states into one confederacy as a republic or constitutional monarchy, and freeing them from foreign influence. This display of revolutionary spirit is nothing new in the history of Italy. The middle ages, that golden period of absolute power, exhibit there an almost uninterrupted series of such political conspiracies, republican schemes, and destructive convulsions, because Italy has never yet been permitted to be politically a nation, and to adopt a form required by its wants and its rights. One leading measure was, to occupy for some years the kingdom of the Two Sicilies and Piedmont (in which the old troops were disbanded), at the expense of these states, with Austrian armies, which had restored the former state of things. This was done conformably with the treaties between Austria and king Ferdinand, of October 18, 1821, and the king of Sardinia, Charles Felix, at Novara, July 24, 1821. But, in compliance with the decrees of Verona (December 14, 1822), the Austrian troops, 12,000 in number, were gradually removed from Piedmont in 1823, and the fortress of Alessandria was surrendered, September 30, 1823, to Sardinian troops. In the same year, after a new Neapolitan army had been organized in Naples, the Austrian garrison, of about 42,000 men, was diminished about 17,000, and, in Sicily,

only the citadel of Palermo continued to be occupied by Austrian troops. The last detachment left the kingdom in 1827. The influence of Austria on the internal administration was likewise every where felt. The police of each state adopted the strictest measures for maintaining internal tranquillity. Secret societies were strictly prohibited (for example, in the Austrian Italian states, by a proclamation of August 20, 1820); tribunals were erected, and, in Naples, supported by moveable columns, to punish the authors of revolutions; executions, proscription, and banishment ensued. Some condemned Neapolitans and Lombards were carried to the Austrian fortresses of Spielberg and Munkatsch. The Neapolitan government proceeded with the utmost rigour against political criminals, as did also the Sardinian and Modenese. Both Naples and Sardinia, nevertheless, issued decrees of amnesty, from which only the authors and leaders of the insurrection were excluded. Notwithstanding this severity, political offences were so numerous, that, in Naples, in January, 1824, a more summary form of judicial proceeding was prescribed to the criminal courts. This was the fourth time, since 1821, that the government had been compelled, on account of the crowded state of the prisons, to have recourse to extraordinary expedients. The Lombardo-Venetian kingdom, Lucca, Parma, Tuscany, and the church displayed the same anxiety in relation to secret associations. In Venice, the court of justice condemned thirty-two, and in Milan sixteen persons to death; but the emperor, in 1823, and January, 1824, transmuted the sentence into that of perpetual or temporary imprisonment. In September, 1821, the pope excommunicated the sect of the Carbonari, and all similar associations, as branches of the long prohibited freemasons; but in the Roman state, Tuscany, Parma, and Lucca, no punishments were inflicted for participation in former political societies. In general, the papal government, under the direction of the cardinal Gonsalvi, was distinguished from the others for conciliatory measures, and for moderation in establishing internal tranquillity. The influence of the apostolic see on the states convulsed by revolutions was thus, in some degree, increased. The press, universities, and schools, were, in particular, closely watched. In the kingdom of the Two Sicilies, and in Piedmont, strict measures were taken for the purification and discipline of the literary institutions; the Jesuits were restored, and rendered influential in the education of youth, by having committed to them, at Rome, and other places, the schools, colleges, and oratories, which they had before conducted. On the other hand, numerous banditti disturbed the public security, especially in Naples and the States of the Church. One of them got in their power (January, 1822), an Austrian colonel, for whose liberation they had the audacity to demand 40,000 Roman dollars; but they released him on seeing themselves surrounded by Austrian troops. In January, 1824, according to the *Diario di Roma*, a numerous band of roving youths was discovered in Italy, who had run away from their parents, organized themselves into companies, and subsisted by frauds and robbery. Among the single events, important for the history of Italy in late times, we must mention the death of pope Pius VII., in consequence of fracturing his leg, August 20, 1823. After a short conclave (from 3d to 27th September), he was succeeded by cardinal Annibal della Genga, born in 1760, at the family castle of the same name, near Spoleto, a prelate distinguished for his diplomatic services; he assumed the name of Leo XII., September 27, 1823.\* In the

year 1825, Leo caused a jubilee to be celebrated in the States of the Church. (See *Jubilee*.) The friend and secretary of Pius VII., the statesman cardinal Gonsalvi, who effected great changes in the system of internal administration, died at Rome, Jan. 24, 1824. He had bestowed the presents received from the European sovereigns (upwards of 100,000 scudi in value), on the college *de propaganda fide*, of which he was the last prefect; and a great sum of money for rebuilding St Paul's church, burned in Rome, in 1823. A somewhat milder spirit prevailed in the Two Sicilies, after the accession of Francis I. (Jan. 4, 1825.)

Italy depends almost solely on its agriculture for subsistence; the sources from which it formerly drew its support, the arts, manufactures, and commerce, being almost dried up. Commerce with foreign countries, which, in Naples especially, is altogether stagnant, is, for the most part, in the hands of foreigners, and, in a great measure, dependent on the British; thence the universal want of specie, the financial embarrassments of the governments, and the loans negotiated with Rothschild. Italy no longer lives, as formerly, on her cities, but on her soil. And even this source of prosperity maintains but a feeble existence, while taxes and tariffs impede the exportation of the staple productions to foreign countries, or bands of banditti and the want of good roads obstruct internal intercourse, as in Sicily and Calabria. The natural advantages of Italy entitle her to the highest rank in agriculture, commerce, and the arts; but all branches of industry groan under political oppression. The government and people look on each other with jealousy and hate, and the ecclesiastical establishment poisons the springs of national activity. A political excitement is continually kept up by means of secret societies, which are found also in Spain and Switzerland, under different appellations—*Consistorato*, *Croceignati*, *Crocefieri*, *Società della Santa Febe*, *Società del Anello*, and of the *Bruti*. The most count Le Maistre was, for a long time, in Piedmont, the head of these malcontents, who sought to accomplish desperate, ambitious plans, while apparently zealous in the cause of religion or morality. Even the Calderari, in Naples, whose head was the examiner of the police of Naples, prince Canosa, have become one with the Sanfedists, who were connected with the *gouvernement occulte* (as it was denominated, of France. These ultras hate even Austria, because it seems to act with too great moderation. The grand duke of Tuscany is a man of lenient principles, and, in that country, not a single Tuscan has been brought to account for political transgressions. Like the rest of Europe, Italy is on the eve of momentous events; but the convulsions in that country will be more violent than in many others, in consequence of its having to struggle at once for unity and independence, against a deeply rooted and obnoxious ecclesiastical establishment, the ignorance of a vast number of the people, and powerful enemies.

For the general history of Italy, previous to the last period, see Muratori's invaluable works: *Annali d'Italia* (12 vols. 4to); *Rerum Italicarum Scriptores*, (28 vols. folio); and Sismondi's *Histoire des Républiques Italiennes* (third edition, 16 vols. 1825). A continuation of Guicciardini's *Storia d'Italia*, circa 1789, by C. Botta, has lately been announced. Percival's *History of Italy*, (2 vols.), contains a shorter view of the modern history of that country. For further information on the modern history and the statistics of Italy, see Carlo Botta's *Storia d'Italia*

was elected pope, March 31. He took the name of Pius VIII., and died in December, 1830. Early in 1831, cardinal Cappellari was elected pope, and assumed the name of Gregory XVI.

\* Leo XII. died Feb. 10, 1829, and cardinal Castiglione

dal 1780 al 1814 (Paris, 1824, 4 vols. 4to, and in French, 5 vols.); the *Annali d'Italia dal 1750* (continuation of Muratori), compilati dal Abbate A. Coppi (3 vols., Rome, 1825); Bossi's *Storia d'Italia antica e moderna*; the *Mémoires sur la Cour du Prince Eugène, et sur le Royaume d'Italie, pendant la Domination de Napoléon*, &c. (Paris, 1824); also, Leo's *Geschichte der Italienischen Staaten* (4th vol., Hamburg, 1830), and the historical works which are mentioned in the subsequent article on *Italian Literature*; also, the above-mentioned work of Lullin de Châtenivieux (*Letters on Italy*). This author investigates the causes of the decline of Italy, and describes regions which are not visited by most travellers. His comparison of the Italian system of agriculture with the English is interesting.

**Italian Language.** The boundaries of the Italian language cannot be given with precision. In the north, towards Switzerland, Tyrol, and the other neighbouring countries, the valleys in which German, Italian, and dialects of the ancient Roman language, are spoken, alternate with each other. Even the sea is not a definite limit. On account of the early extension of the Italians over the islands of the Mediterranean, including those of Greece and the coasts of the Grecian main land, it is not easy to determine where the last Italian sound is heard. It is spoken, more or less corrupted, in all the ports of the Mediterranean, Christian and Turkish. Of late, however, the Italian language has lost ground on many islands, as, for instance, on the Ionian islands. (q.v.) The origin of this beautiful and most harmonious tongue, is also lost in obscurity. The general opinion, that the Italian originated from a mixture of the classical Latin with the languages of the barbarians who overran Italy, is erroneous. The Roman literary language, which the scholar learns from Horace and Cicero, was not the dialect of the common people. That the former could not have been corrupted by the mixture of the barbarous languages, is proved by the fact, that Latin was written in the beginning of the middle ages, long before the revival of learning, with a surprising purity, considering the circumstances. After the language of common life had been entirely changed by the invasion of the northern tribes, in its whole spirit, rather than by the mere admixture of foreign words (a consequence of the change of the spirit of the people), then a new language of literature was formed, though the classical Roman still continued to be used. The new language was opposed to the variety of dialects which had grown out of common life; the formation of it, however, was slow, because the learned and the poets, from whom it was necessary to receive its stamp and development, despised it as an intruder on the Latin, which was venerable as well by its age, and the treasures handed down in it, as on account of the recollections of former greatness, with which the suffering Italians were fond of flattering themselves. Even down to the present day, that idiom, the melody of which carries us away in the most unimportant author, is not to be found as the common idiom of the people in any part of Italy.\* It is a mistake to suppose that Boccaccio's language is to be heard from the lips of Tuscan peasant girls, or Florentine porters. Even the Tuscan and Florentine dialect

differs from the pure language of literature, which, during the first centuries of Italian literature, is found purer in the poets of Sicily and Naples than in the contemporary writers of Tuscany. The circumstance, that the most distinguished Italian poets and prose writers were born in Florence, and the authority assumed by later Tuscan academies, particularly the Crusca (q. v.), are the causes why the Tuscan dialect, in spite of its rough gutturals, which are intolerable to the other Italians,† became predominant in the language of literature. Dante, the creator, as it were, of Italian prose and poetry, and whose works are full of peculiarities of different dialects, distinctly maintains, in a treatise *De vulgari Eloquentia*, that it is inadmissible to attempt to raise a dialect to a literary language. Dante, indeed, distinguishes in the *lingua volgare* (so the language was called, which originated after the invasion of the barbarians) a *volgare illustre, cardinale, aulicum, curiale*; but this sufficiently proves that he held the opinion above stated. Fernow (in his *Roman Studies*, Book viii., No. 11) mentions fifteen chief dialects, of which the Tuscan has six subdivisions. Those dialects, in which no literary productions exist, are not enumerated. The Italian, as we find it at present, in literature and with the well educated, is essentially a Latin dialect. Its stock is Latin, changed, to be sure, in its grammar and construction, by the infusion of the modern spirit into the antique, as the character of the people underwent the same change. A number of Latin forms of words, which, even in the time of the Romans, existed in common language (as, for instance, *o* instead of *um*, at the end of a word), have been, by the course of time and revolutions in literature, elevated to a grammatical rank; and the same is very probably true of forms of phraseology. In many instances, the Italian exhibits changes in the Latin forms, which have evidently taken place in the same way, in which common people, in our days, corrupt the correct modes of speech by a rapid, or slurred, or mistaken pronunciation. This is partly the reason why the Italian has changed so considerably the proportion of the consonants to the vowels in Latin (from 1·2 : 1, the Latin proportion, to 1·1 : 1, the Italian proportion); and this is one of the chief reasons of the great and uniform harmony in the Italian language. A careful investigation will show that, in fact, little admixture of Teutonic words took place, but that it is much more the Teutonic, or modern spirit, which changed the language so considerably.‡ The study of Italian has been carried on, in modern times, with great zeal, and a recurrence to the old writers, has much diminished the influence of the French models, so general after the time of Algarotti. The principles, according to which purity is now judged, have been clearly laid down by count Julius Perticari, son-in-law to Monti, in the work *Amor Patrio di Dante* (Milan, 1820), which powerfully opposes the presumption of the Tuscans in claiming to be in possession of the only good Italian. This work was considered, for a long time, the production of Monti, who, by his *Proposta di alcune Correzioni ed Aggiunte al Vocabolario della Crusca*, gave sufficient reason for such conjecture. To render

\* The sweetness of this tongue, which often gives to a passage a charm independent of the meaning of the words, and resembling that of music, is, in our opinion, no where so apparent as in Tasso's Jerusalem Delivered, and many stanzas have struck us as attracting the hearer irresistibly, though some of them have no particular charm in the meaning of the words. This also gives the Italian improviser a great advantage over one who attempts a similar performance in another language, in which he is entirely thrown upon the meaning of what he says.

† The beau-ideal of Italian is set forth in the saying, *Lingua Toscana in bocca Romana* (the Tuscan dialect in a Roman mouth.)

‡ See the article *Consonant*.

§ This change is also manifest in the difference between authors who wrote before the great revival of letters, and still later, before the French influence had taken place. This may, perhaps, account for the difficulty which an Italian reader finds in understanding many passages of Dante, which do not strike a German as particularly obscure.

the nobler language also the common property of the provinces to which it had hitherto remained foreign, was the aim of Gherardini's *Introduzione* (Milan, 1815). More was promised by the *Vocabolario della Lingua Italiana*, published at Bologna, the authors of which are arbitrary in the explanation and application of words. Bonavilla's *Vocabolario Etimologico* (Milan, 5 vols., 1825) hardly excited the attention of the Milanese, under whose eyes it originated. Romani's *Teoria e Dizionario gen. de Simoni* (Milan, 1825) seems to be more useful. Respecting the history of the Italian language, we may expect much from the profound researches of Benci. The philological treasures of a nation, in which the ancient writers are studied with so much zeal, and which is so extensively connected with foreign countries, must be continually augmenting. Wherever a line of Tasso has been found unprinted, wherever the pen of Guarini has been traced, the fragment has been published with a pious devotion, most probably not desired by the authors. Nevertheless, many interesting additions to the literature of Italy have been made in this way: thus, for instance, a work of Peter Perugino (*Di uno Scritto Autografo del Pittore P. Perugino nell' Archivio dell' Acad. di B. Arti di Perugia*, &c., Perugia, 1820), poems of Bojardo (*Poesie di Matteo Maria Bojardo, Conte di Scandiano ecc. scelte ed illustrate del Caval. Venturi*, Modena, 1820), poems of Lorenzo the Magnificent, *Poesie del magnifico Lorenzo de' Medici*, Florence, 1820), poems of Luigi Alemanni (Florence, 1819), a work of Montecuculi, unknown till it was published by Grassi (Turin, 1820), and letters of Galilei, published by Venturi (Modena, 1821, 16mo, 2 vols.) Still greater has been the demand for editions of the acknowledged classics. Dante has been published in all shapes and sizes. Among these editions, that of *De Romani* (Rome, 1820, 4to), the edition of Biagioli (Milan, 1820), and one published at Roveto, in the Rhaetian Alps, by an admirer of the poet, Aloisio Fantoni (1820), of which a manuscript in the hand-writing of Boccaccio was made the basis, deserve mention. The edition printed from the Bartolinian manuscript (Vienna, 1823) has acquired some distinction among the most recent, as have likewise Scolari's explanations (*Della piena e giusta Intelligenza di Dante*, Padua, 1822). Ugo Foscolo had prepared an edition, accompanied with notes and commentaries, which is now (1831) in course of publication at London. Similar attention has been paid to Petrarca, in the famous edition of Marsaud (Padua, 1819, 4to.), and several editions for common use. Ariosto's *Orlando Furioso* has met with equal homage; the edition at Florence, by Molini (1821 and 1822, 5 vols.), unites every thing which is required for the understanding of the poet. No less care was bestowed on Torquato Tasso in the edition made by the typographical society (Milan, 1823 et seq.), and hardly an Italian author of note can be mentioned whose works have not been carefully edited. The *Società Tipografica de' Classici Italiani* even undertook the reprint of Muratori's *Annali d'Italia* (Milan, 1820 et seq., 20 large volumes), trusting to the zeal for collecting among travelling foreigners, and in so doing were more fortunate than the editor of the *Famiglie celebri Italiane*, which, with all its undisputed merit, has had but a heavy sale. Since the death of Morelli, the spirit of criticism, as regards the classics, seems to have died. The best Italian and English dictionary is that of Petronj. (Italian, French, and English, 3 vols., London.) Alberti (Italian and French) is very valuable. The best modern grammars are the *Grammaire des Grammaires Italiennes*, Biagioli's *Grammaire Italienne*.

*Italian Literature and Learning* (excluding poetry). One consequence of the irruption of the barbarians into Italy was a period of darkness and ignorance, as well as of disorder and distraction, from whose chaotic confusion the germs of a new civilisation could only be developed slowly and laboriously.

*First Period.—From Charlemagne to the Death of Otto III.*, 1002.—The influence of Charlemagne on the friend of letters and the restorer of peace was favourable. We find an Italian, Petrus, deacon of Pisa, mentioned as his teacher in grammar. No less deserving of mention is Lothaire, who was king of Italy in 823, and founded the first public schools in many cities. Of the instructors in these schools, we know only Dungalus of Pisa, of whom, while he was still a monk at Bobbio, Charlemagne requested an explanation of two solar eclipses, and under whose name several works are still extant. Lothaire's example was imitated by pope Eugene II. in the States of the Church. The consequences, however, of these institutions, although valuable in themselves, were unimportant; for competent teachers were wanting, and the later Carolingians and popes suffered the new institutions of learning to fall to decay. In addition to this, the incursions of the Saracens and Hungarians into Italy, and the civil wars, had a very injurious influence. There were few individuals, in this dark period celebrated for learning. In theology, were distinguished the popes Adrian I., the above-mentioned Eugene II., Leo V., Nicolas I., and Sylvester II.; Paulinus, patriarch of Aquileia (his works were published, Venice, 1737), Theodolphus, bishop of Orleans (his works, Paris, 1646), both contemporaries of Charlemagne; the two archbishops of Milan, Petrus and Albertus; Maxentius, patriarch of Aquileia; and, finally, the two abbots of Monte Casino, Autpertus and Bertarius. Among the historians of this time, whose writings contain valuable information, though in a rude and barbarous style, the principal are Paulus Warnefried, surnamed *Diaconus*, author of several works, especially of a history of the Lombards, and Erchempertus, with two unknown persons of Salerno and Benevento, who continued the above work; a priest of Ravenna, by name Agnellus (also Andreas), who wrote a history of the bishops of Ravenna; Andrew of Bergamo, author of a chronicle of Italy from 868 to 873; Anastasius, librarian of the Roman church, known by his lives of the Roman bishops, and Liutprandus of Pavia, author of a history of his own times.

*Second Period.—From the Death of Otto III.* 1002, to the Peace of Constance, 1153. In this period, also, the condition of Italy was unfavourable to the interests of learning. The Italian cities were contending for their freedom with the emperors, and the conflict between the spiritual and secular power was no less injurious. The crusades, which began at the close of the 11th century, salutary as they were in their ultimate influence, contributed, in their immediate results, to augment the general confusion. Of the popes, the ambitious Gregory VII. and Alexander III. took measures for improving the schools. The copies of ancient classic works were multiplied, and individuals took pains to collect books. Among the learned theologians of this period, we must mention Fulbert, bishop of Chartres, a native Roman; the two famous archbishops of Canterbury, Lanfranc and his scholar Anselm; Petrus Lombardus, teacher of theology at Paris, most famous for his four books *Sententiarum*; Petrus Damianus; the cardinal Albericus; Bruno, bishop of Segni; Anselmus, bishop of Lucca; Petrus Gratianus, or Chrysolanus, archbishop of Milan, and Bonifone, bishop of Sutri, afterwards of Piaccenza.

All have left works, on which we shall not dwell. In philosophy, or rather dialectics, besides Lanfranc and Anselm, were distinguished Gerardus of Cremona, who taught at Toledo, and, among other things, translated, from the Arabic into Latin, the works of Avicenna and the *Almagest* of Ptolemy, and Johannes, the Italian, who expounded Plato and Aristotle at Constantinople, and gave instruction in logic. Music underwent an entire transformation through Guido of Arezzo. The medical art flourished in the school at Salerno, at the end of the 10th century. The physicians there seem to have first studied the works of the Arabians. The oldest monument of the Salernian school consists of certain diœtical rules, composed in Leonine verses, entitled *Medicina Salernitana*, or *De Conservanda Bona Valentia*. Several physicians, both of Salerno and the neighbourhood, were distinguished in these times for their works, viz. Matthæus Platearius, Saladinus of Ascoli (the last for his compendium of aromatic medicines), and several monks, whom we pass over. Jurisprudence revived with the freedom of the cities, and became a subject of general study. Throughout Italy there were schools in which it was taught; namely, at Modena, Mantua, Padua, Pisa, Piacenza, Milan, and above all at Bologna, where Irnerius, who acquired for this city the appellation of *learned*, taught and explained the Roman law, and brought to light the concealed treasures of the *Pandects*. We might mention many distinguished lawyers of this period, but content ourselves with citing the famous Gratian, who first digested the canon law (in his *Decretum sive Concordia Canonum Discordantium*), for the use of the tribunals, and is to be regarded as the founder of the canon law. Although the grossest barbarism prevailed in every thing that related to taste, there were, nevertheless, individuals who paved the way to a knowledge of the ancients, by the study of the Greek and Latin languages, and sought to imitate their style. Among them was Papias, one of the first who compiled a Latin dictionary. The 11th and 12th centuries exhibit many scholars, whose works are destitute of elegance, but written in a clear and intelligible style. Such are Arnolphus, the two Landolphuses, Sire Raul, Otho Morena and his son Acerbus, Godofredus Malaterra, and several writers of chronicles, and authors of monastic histories, respecting whose names and works we refer the inquirer to Muratori's invaluable collection.

*Third Period.*—*From the Peace of Constance, 1183, to the End of the 13th Century.* In this period, the literature of Italy assumes a more pleasing aspect. Hitherto all works had been written in barbarous Latin, but attempts now began to be made in the language (rude, indeed, as yet) of the people (*lingua vulgare*). Poetry, as usual, preceded prose. Dialectics and philosophy were improved, and as the sciences gained in solidity and extent, their mutual connexion became more apparent. The crusades had led to new sources of knowledge, and gave, in general, a new impulse to the mind. Notwithstanding the internal wars of Italy, letters flourished; for princes and republics vied with each other in encouraging scholars, and in founding new schools and institutions of education. The emperors Frederic I. and II. effected great improvements. The former promoted the study of jurisprudence in particular, and founded schools; the latter was himself a scholar, possessed an extensive knowledge of the languages, and established public schools throughout the south of Italy. His court, and that of his son Manfred, in Palermo, were thronged with the learned. Besides some poems in Italian, he also wrote a work on the natural history of birds. His learned chancellor, Pietro delle Vigne (Petrus de Vineis), was

animated by the same spirit, and not less familiar with the science of law than with the conduct of political affairs. Besides six books of letters, his collection of Sicilian laws is still extant. Several of the popes were profound scholars, and distinguished as authors, particularly Innocent III. and IV., and Urban IV. The university of Bologna, at the beginning of the 13th century, contained 13,000 students from all countries of Europe; and Padua, Arezzo, Vicenza, Naples, &c., competed with it. The chief theologians of this period were Thomas Aquinas, the Franciscan Bonaventura, and Egidio Colonna, all three authors of numerous works. In philosophy, a new epoch began in Italy in this period, when the writings of Aristotle became known to the Italians, though in a somewhat corrupt state. Thomas Aquinas wrote a commentary on them by the command of the pope, and translated them, partly from the Greek, partly from the Arabic. Brunetto Latini produced an epitome of the *Ethics* of Aristotle, in his *Tesoro*, which was originally written in French, and is remarkable as an encyclopædia of the knowledge of the age. Mathematics and astronomy, in connexion with astrology, were cultivated. Campano, the most learned geometer and astronomer of his time, wrote a commentary on Euclid. After him we may name Lanfranco, Leonardo of Pistoia, and Guido Bonatti, the chief astrologer of the time. From this period dates the invention of spectacles and of the magnetic needle. The school of Salerno was the central point of medical study. It had able teachers in Pietro Musandino, Matteo Plateario, Mauro, &c.; but there were also distinguished physicians out of Salerno, such as Ugo of Lucca, the Florentine Taddeo (who wrote commentaries on the Aphorisms of Hippocrates, and on some works of Galen), Simon of Genoa (author of the *Clavis Sanitatis*, which may be regarded as the first medical and botanical dictionary), and others. Surgery made still greater progress under such men as Ruggieri of Parma (who wrote a *Practica Medicina*), and his countryman and contemporary Rolando (author of a *Surgery*, on which four of the principal physicians of Salerno wrote commentaries), Bruno, Teodorico, Guglielmo of Saliceto, and Lanfranco, of whom we have likewise treatises on surgery; but no science was more zealously or successfully pursued in the 13th century than jurisprudence. In Ferrar, Modena, Milan, Verona, and other Lombard cities, codes were compiled, on which a Dominican, who passed for a performer of miracles, John of Vicenza, bestowed a sort of consecration. The first lawyers of this time were Asso of Bologna (whose *Summa* on the institutions and *Apparatus ad Codicem* have been printed), Ugolino del Prete, also a Bolognese (who incorporated with the *corpus juris* the feudal laws, compiled by Anselmus of Orto, and the decrees of the modern emperors), Accorso, a Florentine (who obtained the surname of *Glossator*, from his having collected the best glosses of his predecessors, and annexed others of his own), Odofredo (author of a commentary on the *Codes* and the digests), &c. In the canon law, Gratian's collection had been hitherto held as authority. To this were now added the four collections of Bernardo of Pavia, of Pietro Collivaccino, &c., which were regarded as works of authority till they were supplanted by the collection made under the supervision of Gregory IX., which even yet constitutes the greater part of the canonical law. To this Boniface VIII. added, in 1298, the sixth book of decretals. Without dwelling on the most distinguished canonists, we pass to the principal historians, most of whom wrote with simplicity and integrity:—Goffredo of Viterbo (a German, who wrote a chronicle, from the creation of the world to 1168, under

the title of *Pantheon*), Sicardus (author of a similar chronicle), Giovanni Colonna (author of an universal history—*Mare Historiarum*), Riccobaldi (author of a similar work, entitled *Pomarium*), the Sicilian Riccardo of San Germano (who relates, with much fidelity, events from 1189 to 1243), Matteo Spinello (whose history reaches from 1247 to 1268, and is the first learned work in Italian prose), Niccolò di Iam-silla, Saba Malaspina and Bartolommeo da Neocastro, (whose works have been published by Muratori). Florence had its first historian in Ricordano Malaspini. The history of Milan was written by Filippo di Castelseprio, and the Dominican Stefanardo of Vimerate, and thus each province and city had its chronicler, whose names we have not room to enumerate. Grammar, which then comprehended the belles-lettres, had been hitherto neglected; but in the thirteenth century, it found students and teachers, as Buoncampagno Bertoluccio, Galeotto (who wrote in Italian, and translated Cicero's rhetorical books into that language), and, above all, Brunetto Latini, Dante's instructor, who has already been mentioned, and of whom, besides his above-mentioned *Tesoro*, we have several other works in prose, such as *La Rettorica di Tullio*, *De' Vizi e delle Virtù*, &c. At the close of this period, we must mention the famous Marco Polo, his father Matteo, and his uncle Niccolò. They were among the first who made distant journeys through Asia, and rendered that part of the world better known to their countrymen.

*Fourth Period.*—From 1300 to 1400. Amid civil disturbances, the sciences continued to make great advances. While the emperors were attempting, in vain, to restore peace to Italy, and subject it to their authority, separate sovereignties and principalities were formed, the rulers of which emulated each other in their patronage of literature. Robert, king of Naples, was the most distinguished in this respect. After him ranked the Della Scala at Verona, the house of Este at Ferrara, the Gonsaga at Mantua, &c. The number of universities increased, and many of them, such as those of Padua, Naples, Pisa, and Pavia, were very flourishing, though Bologna, formerly the first, fell into decay. The libraries were enriched with the works of the ancients, which were rescued from oblivion. Men like Petrarch and Boccaccio, by their researches and studies, rendered lasting services, as the restorers of learning. Both collected books, and the first collected also Roman coins. By the invention of paper, the multiplication of copies of the classics was facilitated. Their corruption by ignorant transcribers soon became evident. Criticism was required to restore them, and Coluccio Salutato, by the collation of several manuscripts, made a beginning in this art, and recommended it to others. Divinity was treated of by numberless scholastic theologians, but by most of them was obscured rather than illustrated. The following deserve honourable mention: Albert of Padua, Gregory of Rimini, Mich. Aiguani of Bologna, Bartol. Carusio of Urbino, Alessandro Fassitelli, who all taught at Paris, besides Porchetto de' Salvatici of Genoa, Raniero of Pisa or of Ripalta, Jac. Passavanti, Simon of Cascia, Peter of Aquila, Bonaventura da Peraga, Marsiglio Raimondini of Padua, and Lodovico Marsigli. Philosophy was highly complicated and obscure, as it was built on the mutilated and disfigured works of Aristotle, assisted by his Arabian commentator, Averroes, whose mistaken explanations were first made known, and were, in turn, expounded and illustrated by the monk Urban of Bologna. The only philosophical writer, who does honour to the age, is the famous Petrarcha, who wrote several Latin works on moral subjects—*De Remediis utriusque Fortune*; *De Vita solitaria*; *De Contemptu Mundi*;

*De Ignorantia sui ipsius et Aliorum*, &c. The rest that was written in the department of morality deserves mention only for the purity of the Italian, such as *Animastramenti degli Antichi volgarizzati*, by Bartolommeo of Pisa. Of the mathematical sciences, astronomy and, in connexion with it, astrology, were most cultivated. The most noted scholars, who devoted themselves to these branches, were Pietro of Albano, and Cecco of Ascoli,—the former distinguished for his *Conciliator*, in which the various opinions of famous physicians and philosophers are reconciled; the latter for an astrological work, for a treatise on the sphere, and his poem *Acerbia*, for which he was burned as a heretic. Besides these, there were Andalone del Nero, who travelled much for the sake of enlarging his astronomical knowledge, and was esteemed by Boccaccio as the first astronomer of his age, and Paolo, surnamed *Geometra*, of whom Villani narrates, that he discovered all the motions of the stars, by means of instruments of his invention, and who is quoted by Boccaccio, as having prepared machines representing all the celestial motions. Jacopo Dondi and his son, Giovanni, gained reputation and the surname *Dall' Orologio*, by an ingenious clock, showing not only the hours, but also the course of the sun, moon, and planets, as well as the months, days, and festivals. Pietro de' Crescenzi, a Bolognese, wrote in Latin his even yet interesting work on agriculture; but, in the same century, there appeared an Italian translation of it, distinguished for its language and style. Medicine was zealously studied by a number of scholars, but was still, however, in a very imperfect state, and deserved, at least in a measure, the ridicule with which Petrarcha treated it. The celebrated school of Salerno was on the decline. The Arabians were everywhere esteemed as models and teachers. Among the most famous physicians of the time, were the Florentine Dino dal Garbo, who wrote commentaries upon some writings of Avicenna and Hippocrates, and on the love songs of Guido Cavalcanti, also a treatise on surgery, &c.; his son Tommaso, Petrarcha's friend, who wrote a *Summa Medicinalis*, and directions how to treat the plague, and explained Galen's works on the difference of fevers and on generation; Torrigiano Rusticelli, who wrote on Galen's *Ars parva*; Gentile of Foligno; Jacopo of Forlì; Marsiglio of Santa Sofia, and others whose works are forgotten; finally, Mundino of Bologna, who was the first that wrote a complete work on anatomy, which was esteemed for two centuries. In jurisprudence, several persons were eminent as writers on civil law: Rolando Placius; Albert of Gandino (*De Maleficiis*); Oldrado da Ponte (*Consilia* and *Questiones*); Jacopo Belviso (who wrote, among other things, on fets); Francesco Ramponi (who explained some books of the *Code*); Cino (q. v.) of Pistoia; and the two most celebrated lawyers of this age—Bartolo and Baldo. In the canon law, which was extended by the Clementine decretals and Extravagants, the most illustrious was the Florentine Giovanni d'Andrea, who commented upon the six books of the decretals, and educated several distinguished scholars. In history, the increasing intimacy with the works of the ancients had the most favourable influence; it was freed from a great many errors and fables. Petrarcha and Boccaccio distinguished themselves by several historical works, written in Latin:—the former by four books, *Arrus Memorandarum*, and biographies of famous men;—the latter by *De Genealogia Dorum*; *De Casibus Virorum et Feminarum illustrium*; *De claris Mulieribus*; *De Montium, Sylvarum, Lacuum, Fluminum, Stagnorum et Marium Nominibus*. In addition to these, there is a long train of authors of general history and of chronicles; especially Benvenuto d'

Inola (who wrote a history of emperors, from Julius Cæsar down to Wenceslaus, and commented on Dante); Francesco Pipino of Bologna (who wrote a chronicle, from the time of the first Frankish kings down to 1314); and Guglielmo di Pastrengo (author of the first universal library of the writers of all nations, which displays a wonderful extent of reading for those times); the Florentine Paolino di Pietro, Dima Compagni, and the Villanis (see *Villani*), who contributed much to the improvement of their native language; the Venetian Andrea Dandolo (who wrote a valuable Latin chronicle of his native city, from the birth of Christ to 1342); and Raffaello Caresini (who continued it till 1388); the Paduan Alberto Musato (who wrote several historical works in good Latin, partly in prose, partly in verse); and others. (See Muratori's *Scriptores*.) The want of proper teachers was a great obstacle, in this period, to the study of foreign languages. Clement V. gave orders, indeed, for the erection of professors' chairs for the Oriental languages, not only in the papal cities of residence, but also in several universities at home and abroad, but with little effect. More was done for Greek literature, especially through the instrumentality of Petrarca and Boccaccio: the two Calabrians Barlaamo and Leonzio Pilato were the most zealous cultivators of it. At Florence, the first professorship of the Greek language was founded and conferred on Leonzio Pilato, by the influence of Boccaccio. In this period occur the first Italian tales and romances. The oldest collection of tales extant is the *Cento Novelle antiche*, short and very simple stories by unknown authors. These were followed by Boccaccio (q. v.) with his *Decameron* and his *Fiammetta*, by which he became the real creator of the Italian prose, in all its fulness, luxuriance, and flexibility: his imitators were Francesco Sacchetti, author of a collection of tales, and Ser. Giovanni, author of *Pecorone*, both, however, far inferior to Boccaccio. Dante (q. v.), too, must be mentioned, both on account of his Italian works, the *Vita Nuova* and the *Convito*, and also on account of his *De Monarchia*, and *De Vulgari Eloquentia*. Connected with this is the *De Rhythmis Vulgaribus* of Ant. di Tempo, which treats, though imperfectly, of Italian verse, as the former had treated of Italian prose, and the various kinds of style. In general, grammar and elegance of style were much cultivated, by reason of the study of the ancients. Not only were the models of antiquity translated and explained, but a professorship was founded at Florence for illustrating Dante. Yet the specimens of elegant prose are few. Among the writers of travels of this century, Petrarca and the Minorite Odorico of Pordenone hold the first rank. The former made a journey to Germany, and gives an interesting account of it in his letters; he also wrote for a friend an *Itinerarium Syriacum*, without having ever been in Syria himself. Odorico travelled through a great part of Asia as a missionary, and, after his return, published a description of his travels, which may be found in Ramusio's work, but unfortunately so altered, that we can hardly venture to give credence to the accounts.

*Fifth Period.*—From 1400 to 1500. During this century, notwithstanding the continuance of internal troubles, Italian literature was in a highly flourishing condition. Two events, in particular, had a favourable influence: first, the conquest of Constantinople by the Turks, in consequence of which many learned Greeks fled to Italy, and diffused knowledge there; secondly, the flourishing state of the house of the Medici in Tuscany, the members of which were distinguished for their patronage of the arts and sciences, and were emulated by the Visconti, Sforza, Este, the kings of Naples, the marquises of Mantua

and Monterrat, the dukes of Urbino, and other princes, popes, magistrates, and private persons. Without dwelling on the universities, we merely say, that two new ones were added at Parma and Turin. In the preceding century, an academy of poetry had been established, and scientific academies were now instituted. The first of this kind was founded by the great Cosmo, at Florence, for the revival of the Platonic philosophy. Similar societies were formed at Rome, at Naples, and, under the patronage of the learned Aldus Manutius, at Venice. Men like Guarino of Verona, Giovanni Aurispa, and Francesco Filelfo, brought the works of the Greeks from obscurity; others were not less zealous in the cause of Roman literature. Public and private libraries were established in several places. This progress was promoted by the invention of printing, which was quickly spread and brought to perfection in Italy. As ancient literature became more generally studied, antiquities likewise attracted greater attention. Ciriaco of Ancona, in particular, thus gained a high reputation. No one of the many learned theologians of these times is much distinguished. We shall merely mention Nic. Malermi, or Malerbi, who first translated the Bible into Italian; Bonino Mombrizio, who collected the lives of the martyrs; and Platina, who, with great erudition, and not without critical acuteness, wrote the history of the popes, in an elegant and forcible style. After the arrival of the Greeks in Italy, a new impulse was communicated to the study of philosophy. Among several others, Paolo Veneto had already acquired fame as a philosopher by his logic or dialectics, and his *Summule Rerum naturalium*, in which he illustrated the physics and metaphysics of Aristotle. Among the Greeks who fled to Italy in the first half of this century, one of the principal was Johannes Argyropolus, of whom Lorenzo de' Medici, Donato Acciaiuoli, and Politian were scholars. "Without entering into controversies, he explained Aristotle, and translated several of his works. But after him, Georgius Gemistus (also called *Pletho*) gave rise to an obstinate contest respecting the relative superiority of Aristotle and Plato. He himself, as the advocate of Plato, ridiculed Aristotle and his admirers. Georgius Scolarius (afterwards patriarch of Constantinople) answered with vehemence, and provoked *Pletho* to a still more violent reply. The famous Theodore Gaza, the cardinal Bessarion, and George of Trebison, took part in the controversy. On the other hand, the admirers of Plato, at Florence, remained quiet spectators. The Platonic academy, founded there by Cosmo, was in a flourishing state. Marsilius Ficinus and Johannes Picus of Mirandola, were its chief ornaments. The former translated the works of Plato into Latin, and wrote on the philosophy of Plato and of the Platonists. Their most eminent successors were A. Politian and Cristoforo Landino. Astronomy was still mixed with astrology. Some of the most learned astronomers were Giovanni Bianchino, whose astronomical tables of the orbits of the planets were several times printed; Domenico Maria Novara, instructor of the great Copernicus; and, above all, Paolo Toscanello, celebrated for the sun-dial made by him, in the cathedral at Florence. Mathematics and music now revived in Italy. One of the restorers of arithmetic and geometry was Luca Paccioli of Borgo San Sepolcro. Leone Battista Alberti, the author of numerous works on architecture, wrote in a manner no less elegant than profound; he was also the author of valuable treatises on other subjects. The first writer on the art of war, was Robert Valturio da Rimini. For music, Ludovico Sforza first founded a public school at Milan, and made Franchino Gafurio its teacher, from whose pen we have several works,

such as a Theory of Music; also, a work on the practice of music, and a treatise on the harmony of musical instruments. Medical science was but little promoted, considering the number of physicians; they were satisfied with collecting the observations of their predecessors. Bartol. Montagna (*Consilia Medica*, and observations on the baths of Padua), Giovanni di Concoreggio (*Praxis nova totius fere Medicinæ*, &c.), Giov. Marliano, likewise an able mathematician and philosopher (a commentary on Avicenna), Gabriel Zerbi, Alessandro Achillini and Nic. Leonicensi (who exposed the errors of the ancients in a particular work, and was perhaps the first who wrote *De Gallico Morbo*), were distinguished in anatomy. Civil jurisprudence still stood in high estimation. In it were distinguished Cristoforo di Castiglione and his scholars, Raffaello de' Raimondi and Raffaello de' Fulgosi, who wrote *Consilia*, and explanations of the digests; Giovanni di Imola, who wrote a commentary on the first part of the *Digestum novum*; Paolo of Castro, who wrote explanations of the code and digests; Pietro Filippo Corneo, who left legal *Consilia*; Antony of Pratovecchio, who improved the feudal law, and wrote a *Lexicon Juridicum*; Angelo Gambiglione, who wrote *De Maleficiis*, &c.; the great Accolti of Arezzo, Alessandro di Imola, surnamed *Tartagni*, who left many law treatises on the digests, the code, the decretals and Clementines, many *Consilia*, &c.; Bartol. Cipolla, who wrote *De Servitutibus*; Pietro da Ravenna, who, besides several legal works, wrote rules for the art of memory, under the title *Phoenix*; Bartol. Soccino and his opponent, Giasone dal Maino, and many others. In canonical law, the most famous authors were Nic. Tedeschi, Giov. of Anagni, Ant. Roselli, Felino Sandeo and the cardinal Giannantonio da San Giorgio. History made the greatest progress; it aimed not only at truth, but also at beauty of diction. Among the many historians of this period, some may be regarded as models of historical description. Roman antiquities and ancient history were treated of by Biondo Flavio, whose principal works are *Roma instaurata*, *Roma triumphans*, *Italia illustrata*, *Historia Romana*, *De Origine et Gestis Venetorum*; Bernardo Rucellai (*De Urbe Roma*); Pomponio Leto (*De Antiquitatibus Urbis Romæ*, *De Magistratibus Romanorum*, *Compendium Historiæ Romanæ*), &c.; and Annio of Viterbo, whose *Antiquitatum variarum Volumina XVII.* contain the works of ancient authors, now acknowledged to be spurious. Histories from the beginning of the world to their own times, were written by the archbishop Antonio of Florence, Pietro Ransano, Jac. Filippo Foresti, Matteo and Matthia Palmieri, and Sossimeno, all of which are valuable only as far as they treat of their own times. As historians of their times, and of their country in general, the following are deserving of notice: *Æneas Sylvius*, afterwards pope Pius II., who left a great number of historical works, and whose history of his own times has been continued by cardinal Jacopo Ammirato; Giov. Mich. Alberto of Carrara, Leonardo Bruni of Arezzo, the Florentines Poggio and Bartolommeo Scala; the Venetians Marco Antonio Sabellico, Bernardo Giustiniano; the Paduans Pietro Paolo Vergerio and Michael Savonarola (the physician); the Vicentine Giambattista Pagliarini; the Brescian Jacopo Malvezzi and Cristoforo da Soldo; the Milanese Andrea Biglia, Pietro Candido Decembrio, Lodrisio Crivelli, Giovanni Simonetta, Giorgio Merula, Donato Bozzo, Bernardino Corio and Tristano Calchi; the Neapolitans Lorenzo Valla, Bartolommeo Fasio, Antonio Panormita, Gioviano Pontano, Michele Ricci, Giovanni Albino, Tristano Caraccioli, Antonio Ferrario and others, to whom is to be added

Pandolfo Colleannuccio of Pesaro, the only one who wrote a general history of Naples. Giorgio and Giovanni Stella, and Bartolommeo Senesrega and Jacopo Braccello wrote the history of Genoa. Savoy had, in this period, two historians,—Antonio of Ami (who wrote a chronicle of his paternal city in verse) and Benvenuto da San Giorgio (a history of Montferrat, accompanied with documents). As an historian of Mantua, Platina deserves mention. As geographers were distinguished Cristoforo Buondelmonte, who travelled in Asia; Francesco Berlinghieri, who wrote a geographical work in verse; Caterino Zeno, who described his travels through Persia; the famous navigators Cada Mosto, Amerigo Vespucci and Cabotto (Cabot) and others. In the Oriental languages, Giannomo Manetti was distinguished. The study of the Greek language was spread by Manuel Chrysoloras, Lascaris, and many other Greeks, who fled to Italy, on whom and on their scholars, some of them men of great learning, we cannot here dwell. With no less zeal was Roman literature cultivated. The names of Guarini, Aurispa, Filelfo, Lorenzo Valla, and Angelo Poliziano, are distinguished.

*Sixth Period.*—From 1500 to 1650.—In this period, Italy attained the summit of its greatness. Its rich materials for satisfying both the physical and intellectual wants of man; the power of its republics and princely houses; their seal and munificence in favour of all that could restore the splendour of ancient times, made Italy a model for the rest of Europe. The wars which Ferdinand the Catholic, Maximilian I., Charles V., and Francis I. prosecuted on her soil, did not, therefore, produce permanent injury. The former universities continued, and new ones were added, among which that of Padua was eminently conspicuous. The number of academies and libraries increased to such a degree, that hardly a city of importance in Italy was without them. Among the popes, there were many patrons and promoters of the arts and sciences, particularly Julius II., the magnificent Leo X., Clement VII. (whose unfavourable circumstances did not allow to accomplish his designs, but whose place was supplied, in many respects, by the cardinal Hippolytus of Este), Paul III., Gregory XIII., (who, as Ugo Boncompagni, had edited an improved and enlarged edition of the *Corpus Juris canonici*, and, as pope, corrected the calendar), Sixtus V. (who removed the library of the Lateran to the splendid palace of the Vatican, and enlarged it, completed the publication of the works of Ambrosius and of the Septuagint, caused a new edition of the Vulgate to be published, &c.), and Urban VIII. (who united the Heidelberg library with the Vatican, and founded the Barberini.) We must next mention, as scholars and patrons of scholars, the cardinals Bembo, Carlo, and Federico Borromeo (the last was the founder of the Ambrosian library at Milan), and Agostino Valera. The princes were not behind the popes and cardinals. The most distinguished for activity and liberality were the Gonzaga of Mantua, the Este at Ferrara, the Medici at Florence, and the duke Charles Emmanuel I. of Savoy. Notwithstanding favourable circumstances, theology made but slight advances. For after the storm of reformation had broken out in Germany, established doctrines were more obstinately maintained, and farther investigation discouraged, with the exception of the editions of the Septuagint and Vulgate already mentioned. The study of the Holy Scriptures gained but little by the literary treasures that Italy possessed. Cajetan, the most celebrated commentator on the Bible, offered nothing worthy of note; and Diadati's translation, as it was not modelled servilely on the Vulgate, found no favour among the defenders of the established

cardinal Bellarmine surpasses all the others in intrinsic merit. Cesare Baronio, the historical defender of the disputed papal prerogatives, brought to light the most important documents and monuments; and Paolo Surpi, the assailant of them, united modesty, and incorruptible love of truth, with the deepest insight into the Catholic religion. But, notwithstanding all exertions to uphold the established doctrines of the church, the active spirit of philosophy could no longer be restrained, not even in Italy. Besides the scholastics in the monasteries, and the Peripatetics among the Humanists, who revived and explained the ancient systems of philosophy, there appeared a philosophical sect of free-thinkers, who, together with the superstitions, rejected religion also. Pietro Pomponazzi, who taught annihilation after death, left behind a numerous school of sceptics, to which belonged scholars like cardinal Gonsaga, Contarini, Paul Jovius, and Julius Cæsar Scaliger. By their side stood Bernardino Telesio, also a preacher of infidelity, like Pomponazzi and his school, honoured by the great, while Cesare Vanini and Giordano Bruno atoned for a smaller measure of impiety at the stake; and Campanella, who, as the opponent of Aristotle, and an independent thinker, prepared the revolution that took place in the seventeenth century, languished in prison. This spirit of inquiry gave an impulse to mathematics and physics. B. Telesio, Giordano Bruno, and Th. Campanella endeavoured to deduce the phenomena of nature from general principles. Hiero. Cardanus united these speculations with mathematics. The great Galileo brought mathematics and natural philosophy into the closest connexion by new experiments, and became a model to all, especially to the naturalists of his native country. In mathematics, Tartaglia, Cardanus, and Bombelli were distinguished for their labours in algebra; Buonaventura Cavalieri prepared the way for the infinitesimal calculus; Commandino became celebrated for his labours on Euclid's Elements, and Marino Gheraldi explained Archimedes' theory of hydraulics. Luca Valerio enlarged the limits of mechanics by his discoveries; Castelli produced a revolution in hydraulics; Maurolico opened the way in optics; Della Porta invented the camera obscura, and made the first experiments in aerometry; Grimaldi discovered refraction; Magini perfected the burning glass; Torricelli invented the barometer, and Riccioli made important celestial observations. Natural knowledge was amplified in all its branches. As students of the human frame and anatomists, Fracastoro, Fallopio, Piccolomini, Aggiunti, and Malpighi were celebrated. Ulyss. Aldrovandi travelled through Europe, to investigate the natural history of quadrupeds, birds, and insects, and established a botanical garden at Bologna. Similar gardens were laid out by the university of Padua, by Cosmo duke of Florence, and various private persons. As botanists, Mattioli, Fabio Colonna, and the above mentioned Malpighi, were distinguished. The academy of the Lincei laboured in the cause of natural history from 1625 to 1640. The first professorship of chemistry was founded at Pisa, in 1615. In physics and medicine, the men of most note are Fallopio and his great scholar Fabricius ab Acquapendente (who led Harvey to the discovery of the circulation of the blood), Borelli, Torricelli, Bellini, Malpighi, and Alpini. Among the jurists of this period, we find no great names after the age of the scholastics. History was cultivated with greater success. Historians and historical inquirers treated particularly of native history; Carlo Sigonio wrote a general history in Latin, Girolamo Briani in Italian, and, finally, Guicciardini in a classic style, in which his continuation, Adriani, is inferior to him. In local

history, Macchiavelli's History of Florence was the earliest masterpiece of modern times. Davila, Bentivoglio, Bembo (both for his History of Venice—a continuation of the work of Andrea Navagiero—and for his *Acolani* and Letters), Angelo di Costanzo. Varchi, Paolo Sarpi, the cardinal Bentivoglio and others, are likewise celebrated. Numberless are the historical, geographical, and topographical descriptions of single states, districts, cities, and even of monasteries, libraries, and cabinets. Men like Paolo Giovio, Giambattista Adriani and Vittorio Siri were assiduous in preserving the memory of the literary services of their contemporaries and predecessors. Since the end of the fifteenth century, Venice had been the centre of diplomacy and politics. Much was written there on political subjects, as Sansovino's work on Government, and Botero's State Policy. The study of the Oriental languages was promoted by religious motives. The Maronites on mount Lebanon were received into the Catholic communion. In order to render the union indissoluble, Gregory XIII. erected a Maronite college in Rome, and established for its use an Arabic press. Sixtus V. added salaries. This institution transplanted Oriental literature to Rome, and carried thither a great number of manuscripts. George Amira (who wrote the first Syriac grammar of consequence), Ferrari (who compiled the first Syriac dictionary), Gabriel Sionita and Abraham Ecchellensis were distinguished. From Roman presses issued the Arabic works of Ebn Sina, the geography of Sherif Edrisi, the Arabic commentary on Euclid. At Genoa an Arabic, and at Rome an Ethiopian Psalter had been previously printed. Giggeus published at Milan the first complete Arabic Dictionary, and Maraccius, at Padua, the first edition of the Koran, illustrated by a commentary. Thus Italy was the seat of the study, not only of the Hebrew, but also of the other Shemitish languages. The study of the ancients must have been increased to a great degree, after the art of printing had multiplied the copies of their works. Francesco Robertelli, Julius Cæsar Scaliger, Pietro Vittorio, and Fulvio Ursino, deserve the name of philologists. Others paid more attention to the information afforded by the ancients, and this study was facilitated by translations. Monuments of antiquity were collected, examined, and explained with zeal. Mazzochio, and still more Andrea Fulvio, beginners, indeed, in the science, published ancient Roman inscriptions on coins. Giacomo and Ottavio di Strada made similar researches with greater success, and at length Fulvio Ursino illustrated this department with treasures of erudition. After him, Francesco Angeloni and Giovanni Pietro Bellori, Filippo Buonarrotti, Filippo Paruta and Leonardo Agostino acquired reputation. But, in consequence of the study of the ancients, classical perfection of style became the aim of literature. The historians distinguished in this respect have already been named. Of a similar character, in point of style, are Sperone Speroni (*Dialoghi* and *Discorsi*), Annib. Caro (*Lettere Famigliari*, &c.), Castiglione (*Il Cortegiano*), Della Casa (*Il Galateo* and *Lettere*), Giovanbattista Gelli (*Dialoghi*), Franc. Berni (*Discorsi* and *Capricci*), Pietro Aretino (*Ragionamenti*, &c.), Nicolo Franco (*Dialoghi* *Piacevolissimi*), the two poets Bernardo and Torquato Tasso (the former for his Letters, the latter for his Philosophical Essays and Dialogues); finally, Pietro Badoaro (*Orazioni*), Alberto Lollio (*Lettere* and *Orazioni*), Claudio Tolommei and others. The *Cicalate*, as they were termed (academic prate), pieces in ridicule of the academies, published after the foundation of the Crusca, in the last half of the sixteenth century, are valued principally in point of style. The early novelists found several imitators

in this period; Bandello (q. v.). Firenzuola, Parabosco, Massucco, Sabudino degli Arienti, Luigi da Porto, Molza, Giovanni Brevio, Marco Cadamosto, Grazzini, Ant. Mariconda, Ortensio Lando, Giov. Francesco Straparola, Giambattista Giraldis, called *Cinthio*, to which are added the romance writer Franc. Loredano and the original Ferrante Pallavicino. Criticism began at last to erect its tribunals; but the principles on which it judged were vague and indefinite. This is proved by the contests respecting Tasso's *Jerusalem Delivered*, Guarini's *Pastor Fido*, by Tassoni's attack on Petrarca, &c. There was no want, however, of theoretical works. By his excellent essay *Della Volgare Lingua*, Bembo became the father of Italian criticism. Trissino (Poetics) and Castellano are not without merit. Claudio Tolomei wrote rules for modern poetry; Sperone Speroni, *Dialogues on Rhetoric* (Sansovino, Cavalcanti and others had already preceded him); Benedetto Varchi, a *Dialogue on the Tuscan and Florentine Language* (on occasion of the contest between Caro and Castelvetro); and Foglietta, *On the Manner of writing history*.

*Seventh Period.*—From 1650 to 1820. Hitherto, Italy had been the instructress of Europe, but, in the middle of the seventeenth century, it began to sink from its literary eminence. The principal causes of this change were the restrictions on the freedom of thought and of the press, which had been constantly increasing, ever since the reformation, and the decrease of wealth since Italy had lost the commerce of the world. The moral corruption, which became more and more prevalent, had enervated the physical strength of the people, and deprived the mind of its vigour and energy. The long subjection to foreign powers had created a servile feeling. The nation was afflicted, from 1630 to 1749, by numerous wars, and at length sunk into a lethargy and a stupid indifference to its own greatness. Some popes, princes, and even private persons, were, nevertheless, the active patrons of letters. At Florence, Sienna, Bologna, Turin, Pisa, institutions were established, some at great expense, by Leopold de' Medici, the count Marsigli Pazzi, &c., which promoted the cultivation of mathematics and natural science. Clement XI. Benedict XIII. and XIV. Clement XIV., men of great learning and enlightened views, together with the cardinals Tolomei, Passionei, Albani (Annibale and Alessandro) and Quirini, and, in later times, the cardinal Borgia, the learned Venetian Nani, and the noble prince of Torremuzza, rendered the greatest services. The reign of Maria Theresa and Leopold was favourable to Lombardy and Florence. But none of the sciences, except the mathematical and physical, made much progress. After Machiavelli, politics had no general writer of importance; only single departments of the subject, far removed from danger of collision with the doctrines of the church, were treated with spirit by Beccaria and Filangieri. Philosophy continued scholastic: Italy neither invented any new system, nor gave admission to the systems of foreign countries. Theology gained not a single thinker. Though highly esteemed in his native country, the dogmatic system of Berti was of little value. The works of Ughelli and Lucentius, entitled *Italia Sacra*, evince the industry of the compilers; as do Galland's *Library of the Fathers of the Church*, and Mansi's *Collection of Councils*. Bianchini's fragments of old Latin translations, and De' Rossi's various readings of the Hebrew text of the Old Testament, are valuable; but Scriptural criticism and exegesis have produced nothing in Italy important for foreign countries. The authority of the Vulgate is still unimpaired, and the translation

of the Florentine Antonio Martini, celebrated for its pure style, was made from it. But for the study of the Asiatic languages and literature, the missionary zeal has had the most beneficial results. The learned J. S. Assemani published rich extracts from Oriental manuscripts. The Propaganda formed excellent Oriental scholars, and published several Arabic alphabets and grammars. As regards the critical study and illustration of the ancient classics, the Italians have remained behind other countries. The most eminent scholars in the department of Latin literature are Volpi, Targa, Facciolo, and, as a lexicographer, Forcellini; in that of the Greek, Massonchi and Morelli. Much more was done in investigating, copying, describing, and illustrating antiquities, especially after Winckelmann had taught the Italians to examine them, not only in a historical and antiquarian point of view, but also as works of art. This study led likewise to the investigation of the primitive languages of Italy, especially the Etruscan. Gori, Maffei, Lami, Passeri, opened the way for Lanzi. Polite literature, particularly elegant prose, of which alone we here speak, continued to decline till an effort was made, after the time of Voltaire, to imitate the French. Then Algarotti wrote *Dialogues on Optics* elegantly and propaenously, but superficially; Bettinelli, *On Improvements in the Fine Arts*, with much spirit; Beccaria, *Crimes and Punishments*; Filangieri, *On Legislation*, with dignity and simplicity; Gasparo Gozzi, *Dialogues*, in a pure and agreeable style. In history and its auxiliary sciences, little was done in the period. Giannone was eminent in local, Drusiani in general history. As an investigator and collector of historical materials, Muratori acquired a lasting reputation; Maffei also should be honourably mentioned. Manni laboured for the illustration of seals, and of genealogy. Still less was done in geography. The most celebrated geographer of Italy is the Minorite Vincenzo Coronelli, who established a cosmographical academy at Venice and whose loss (1718) has never been supplied. Even among travellers, there are but few prominent. Something was done by Martini, who travelled through Cyprus, Syria and Palestine; Sestini, who travelled through Sicily and Turkey; Grisellini, who travelled through Inner Austria and Hungary; and Acerbi, who travelled in the North. No jurist, except Beccaria and Filangieri, effected any thing of importance. But the works which appeared in the mathematical, physical, and medical sciences still form the boast of Italian literature. Frisi and Girolamo Mazzochelli were great masters in mechanics, hydrostatics, and hydraulics; Borelli and Mascheroni in the higher analysis and geometry. In mensuration, Lorgna, Fontana, Cagnoli, Ruffa, and Casella are respected names even in our day. Manfredi Settala made a celebrated burning glass. Cassino enlarged the bounds of astronomy by great discoveries; Campani was distinguished for preparing optical glasses; Torelli explained the elements of perspective with geometrical strictness; Zucchi presented the world with valuable celestial observations; and Piazzi acquired renown as the discoverer of Ceres. Physics, for the promotion of which several institutions were active in various places, made the greatest progress. Marsigli, Landriani, Felice Fontana, Toaldo, Tiberio Cavallo, Giovanni and others enriched it by important discoveries. Botany was advanced by Malpighi, Giovanni Del Franchi, Micheli, Giuseppe, Ginnia, Vittorino Egnati, &c. The Italians were successful in the use of the microscope. With its assistance, Redi wrote classical works on natural history, Valart, Felice Fontana, Lamaro Spallanzani, made a great

number of observations. With all the lovers of natural science and of chemistry, Volta is an honoured name. In the study of the natural history of man and of anatomy, Gagliardi, Malpighi, Paolo Manfredi, and, after them, Valsalva, Santorini, Fantoni and Morgagni were distinguished. Practical medicine likewise was not neglected. Franc. Torti taught the use of Peruvian bark; Rammasini trode in Sydenham's footsteps in pathology and therapeutics; Borelli, Baglivi (who followed Hippocrates, however, in practice), Guglielmini, Bellini and Michelotti made Italy the birthplace of the latromathematical school in medicine. In literary history, the labours of Crescimbeni, Quadrio Fontanini, A. Zeno, Mazzucchelli Fabroni, Tiraboschi, Cornioni and others (of Artengia, for example, for the history of the opera), are highly valuable.

*Eighth Period.—Italian Literature of the present Day, since 1820.* Of late years, the literature of Italy is not to be compared, either in extent or in profundity, with the literature of the neighbouring countries. The indolence which springs from a too favourable climate, the restraints arising from the political state of the country and the condition of the look trade, which, in several parts of the peninsula, is under great restrictions, oppose serious obstacles to the free interchange of ideas. The infringements in one city on the copyrights of others increase these difficulties. The universities of Pavia and Padua still maintain their hereditary reputation, and augment it by a zealous cultivation of the natural sciences; Pisa may stand next to them; Sienna and Perugia have made less effort to deserve the notice of foreign countries, and the universities of Rome, Naples, and Turin are of a limited character. With these universities, to which, in Lombardy, gymnasia and elementary schools afford suitable preparation, a number of academies are appropriated to every department of science and art, though they are not all so active as the Lombardo-Venetian institution at Milan, which has published several valuable volumes of memoirs. Names like Oriani, Carlini, Breislak, Configliachi, Brunatelli, are the best pledges of its devotion to the exact sciences. After it, the academy at Turin (*Memorie della R. Accad. delle Scienze di Torino*, vol. xxx., 1826), and the scientific society of Modena (*Memorie della Società Ital. delle Scienze residente in Modena*, t. 19), deserve honourable mention. Foreign countries rarely hear any thing concerning the scientific bodies of Naples. The Herculanean academy at present pays, for the most part, with promises, and the sessions of many other academies are mere ceremonies. The *Crusca* and the *Accad. de Georgofili* at Florence, with the *Accad. Archeologica* at Rome, alone sustain their place in the memory of foreign countries. Among the periodicals, the *Biblioteca Italiana* is a work of merit, and exerts a decisive influence by means of sagacious criticisms; but it has been often disfigured by injustice and harshness, especially when under Acerbi's guidance. Brugnatelli and Configliacchi's *Giornale di Fisica, Chimica, Storia naturale, Medicina ed Arti*, is the periodical most deserving the notice of foreign countries. The study of the Oriental languages, in Italy, is not so much advanced as in other countries. Gr. Castiglioni's explanation of the coins in the cabinet of Milan has found an impartial critic in Frahn of Petersburg; and Rampoldi's *Annali Musulmani* (Milan, 1823, 5 vols.) display a judicious and critical use of Oriental sources. Much has been done for the diffusion of the knowledge of the Armenian language by the publications of the Metocharists of St Lazzaro, in the vicinity of Venice; and father Auger, the Venetian editor of Moses of Chorene, and the discoverer of an ancient Armenian translation of Philo

(Ven., 1822), is said to be distinguished for knowledge of the language. Europe acknowledges Angelo Maio's merits in increasing the means of acquiring a knowledge of ancient classical literature. The discovery of the fragments of Cicero *De Republica*, and of so many other remnants of a classic age (though the complete *Fronto* did not correspond to its fame and the general expectation), give Maio lasting claims to the gratitude of scholars. Maio's success induced professor Peyron, at Turin, to make similar searches into the treasures of the public library intrusted to him, and his sagacity was not altogether fruitless. Mazzuchelli of Milan contributed to the extension of ancient literature by the *Johanneis* of Corippus (Milan, 1820), and Rossini by the publication of Eudemos, from Herculanean manuscripts. Ciampi, after his return from Warsaw to Italy, Manzi, Amati, Nibby, are among those who have rendered service to classical literature by valuable commentaries. The count Ippoliti Pindemonti's translation of the *Odyssey* (Verona, 1822, 2 vols.), the odes of Pindar, by Mezzanotte (Pisa, 1819 and 1820, 2 vols.), and the Isthmian odes (*Le Odi Istmiche di Pindaro traduzione di Gius. Borghi*, Pisa, 1822), by Borghi, Mancini's *Iliad*, in stanzas (Flor. 1824), can satisfy those only who do not exact a strict fidelity of translation. Among the translations from modern languages into the Italian, are the works of Sir Walter Scott and Byron. Klopstock's *Messiah* was translated by Andrea Maffei. Bossi's *Storia d'Italia antica e moderna* (Milan) dwells very long on ancient times, and shows very frequent traces of French influence. There still appear historical works, which are better received by foreigners than by the country to which they belong; as the above-mentioned *Famiglie celebri Italiane* of the count Pompeo Litta (Milan, since 1820); the *Storia di Milano*, by Rosmini; the *Codice diplomatico Colombico Americano* (Genoa, 1823); Scina's *Prosp. della Storia letter. della Sicilia*, and Spoto's excellent *Storia letter. della Liguria* (Genoa, 1824); Beucci's *Elogi*, and Affo's *Vita di Pierluigi Farnese*, though the last belongs to the more favourite department of biography, for which materials may be found in Pelli's *Memorie per la Vita di Dante* (Florence, 1823); Nelli's *Vita e Commercio Letterario di Galileo Galilei* (Florence 1793, but not published till 1820), and contributions in the *Biografia Cremonese*, by Lancetti, and in the Italian edition of the *Biografia Universale* (Venice, Missaglia). One hope, however, notwithstanding such are the signs of the times, remains to the friend of Italian literature, that the abundance of monuments of former times in this land will always preserve alive historical recollections. The explanation of the present gives an opportunity to recur to the past, and to animate its dim recollections by their connexion with tangible realities. How interesting, for example, is the history of the cathedral of Milan! But Italy's associations are not limited to Christian times. *L'Italia avanti il Dominio de' Romani*, by Micali (new ed. Livorno, 1821, folio), indicates the point to which the inquirer may ascend. Investigations connected with ancient monuments cannot be wanting in a country where so much remains to be explored. Inghirami's *Monumenti Etruschi o di Etrusco Nome*, the illustrations of the editor of the *Galleria di Firenze*, so far as they relate to ancient monuments; the Memoirs of the archaeological academy of Rome, and the rare works of the Bourbon academy, are among the phenomena not to be overlooked in foreign countries; and the essays of Nibby, Fea, Borghesi, Lama, Cattaneo, and Brocchi, unite solidity with perspicuity and a comprehensive survey. But how little the proper mode of treating this department is understood, may

be seen from Vermiglioli's *Lezioni elementarie di Archeologia* (Verona, 1822, 2 vols.), which are as useless to foreign countries as Labu's investigations on Roman inscriptions, which either treat of what is well known, or explain obscurely whatever they give of new. The *Raccolta di Antichità Greche e Romane ad Uso degli Artisti, dis. ed Incise da Gio. Bignoli*, is not without merit. The activity of the trade in works of art in Italy, promotes also the publication of views of the monuments of the middle ages (for example, the *Monumenti sepolcrali di Toscana*, the *Raccolta degli migliori Fabbriche, Monumenti ed Antichità di Milano*; the *Fabbriche di Venezia*, Franchioni, Cisa di Gresy, Piola, Venturoli, Bonati), for explaining which associations of men of talent have been formed. Almost every book of travels by an Italian, presents inquiries into the remains of antiquity; and Belsoni, who first kindled the enthusiasm of the succeeding travellers for investigating the remains of the Egyptian art, only followed the taste of his country. Della Cella, the naturalist Brocchi, one of the most intelligent of the late writers of Italy, the learned writer on numismatics Sestini, and Camillo Borghese, prove this position. It is not, however, so much the custom in Italy to embellish travels with engravings as it is in France and Britain. Even the descriptions of cities, of which new ones are ever in demand, are without this embellishment, and retain their old defects. Italy is more independent in the exact sciences than in literature, properly so called, particularly in the physical department; and, by its mathematicians, astronomers, naturalists, has acquired a reputation, to which it has been less true in the fine arts, with the exception of the plastic arts. Where men like Sangro, Flauti, Borgnis, Brunnacci, Lotteri, Bordoni, employ themselves in geometry and its application to geodesy and mechanics; where astronomers like Plana, Brambilla, Inghirami, Oriani, Carlini, Piazzi, Cacciatores, De Cesaris, are engaged in observatories like those at Naples, at Palermo, at Milan, Turin, Bologna, Florence, Rome.—the sciences must make a rapid progress. The *Correspondance astronomique* of baron Zach (see Zach) afforded the Italian scholars an opportunity to make their discoveries and researches known to the rest of Europe. Zach, who lived in Genoa till 1827, promoted thence the diffusion of useful knowledge connected with his science, by an *Almanacco Genovese*. Unhappily, a part of the strict mathematical investigations is buried in the transactions of literary societies; for example, in the Transactions of the royal academy of sciences at Naples; in the Transactions of the Pontonine society (Naples, 1819); in the Memoirs of the Lombardo-Venetian institute; in the reports of the scientific society at Modena; in the *Ricerche geometriche ed idrometriche fatte nella Scuola degl' Ingegneri pontifici d'Acque e Strade* (Rome, 1820), which but too rarely pass the Alps. Geodesy, especially, is prosecuted with great ardour, and two trigonometrical measurements, connected with each other, have given satisfactory results. Equal zeal is manifested in the physical sciences, in which names like Zamboni, Brugnattelli, Configliacchi, Bellingieri, and Ranconi answer for the exactness of the observations and correctness of the calculations. The experiments on magnetism and electricity (Banarelli) have excited a lively interest even in Italy, and Configliacchi's and Brugnattelli's *Giornale di Fisica, Chimica, Storia Naturale, Medicina ed Arti*, which is published very regularly, gives the best account of their variety and thoroughness. Even the *Opuscoli scientifici di Bologna* are almost exclusively devoted to the natural sciences in the widest comprehension, and maintain an honourable name. The geological observations

of the count Mazzini Pencati, who thought himself able to refute by ocular evidence the Wernerian theory of the formation of the earth, have attracted much attention. Among the geologists of Italy must be mentioned the talented and learned Brocchi (who died in 1827, in Egypt), the author of the *Geologia subapennina*, and who, by his interesting essays, did much towards increasing the popularity of the *Bibl. Ital.* Renier, Corniani, Monticelli, and Conelli (*Prodromo della Mineralogia Vesuviana*) keep up the interest in these studies. Patronised by government, the physical sciences have received the most extensive application to agriculture and technology, which have made respectable progress, at least in the north of Italy. New branches of industry, as well as new kinds of plants (rice from China, and grain from Mongolia), have been introduced; and the art of rearing silk-worms, manufacturing wine, and managing bees, has been made the object of public investigation, and the results have been very favourable. The labours of the *Accad. de' Georgofili* at Florence, have contributed much to the promotion of agriculture. Botany cannot be slighted in the Garden of Europe. Savii's *Elementi di Botanica* afford foreign countries nothing new, but the works of Sebastiani, of Mauri, of Brignoli, Moriconi, Tironi, of the superintendents of the gardens at Pisa, Rome, Naples, Palermo, evince the interest which is taken in this department; and the *Pomona in Italia* of Pizzagalli, and Degaspari and Bergamaschi's *Osservaz. Micologiche*, evince the zeal of the authors. The investigation of the higher economy of nature has received valuable contributions from Brunatelli, Configliacchi, from Angelini, Mezzacorona, the describer of the *Proteus anguinus*, Ramazzini, Petagna, Laurenti, and Cavolini; and the structure of the human body was illustrated by Palletta, Mezzacorona and others. The medical literature of Germany has attracted much attention, and several of the most distinguished German writers in the department have obtained successful translators and editors, especially for the use of the lecturers at Pavia, Padua, and Bologna. Many of the German works in the department of metaphysics have been also translated, although the French, like Destutt de Tracy, accorded more with the taste of the Italians. Besides Gioia, the author of the *Ideologia esposta*, Talia, the editor of a *Saggio di Estetica*, German Simoni, and some unsuccessful commentators upon Beccaria, the *Collezione de' classici Metafisici* (Pavia, 1819—22) was, perhaps the best production in the department. De' Simoni has treated of natural law. Numerous explanations and editions have appeared of the Austrian code, which is possessed of great authority in some of the states that speak Italian. It is worthy of mention, that Lorente's History of the Inquisition, and Sismondi's History of the Italian Republics of the Middle Ages, may be freely sold in the Italian states, while they are strictly prohibited by the neighbouring states.

*Italian Poetry.* Italian poetry sprang from the Provençal, which was the first to flourish in Europe on the revival of civilization, and which was also communicated to Italy. Until the thirteenth century we find in Italy only the poetry of chivalry by the Provençals and Troubadours. These wandering bards, intelligible to the Italians, and particularly to the Lombards, by the affinity of their sister language, traversed Italy, and were welcome guests at the courts, especially of the nobles of Lombardy, at a time when poetry was considered as indispensable to feasts. An instance of the estimation in which Troubadours (q. v.) were held, as the chief ornaments of a princely court, is found in the visit of Ramon Berlinghieri, count of Barcelona and Provence.

Frederic Barbarossa, the German emperor, at Turin, in 1162, attended by a train of Provençal poets. The emperor was so delighted with their *gaya ciencia*, that he not only made munificent presents to the minstrels, but also composed a matrilial in their language himself. At the court of Azzo VII. of Este, at Ferrara (1215—1264), some distinguished Provençals—Rambaldo di Vacheiras, Raimondo d'Artes, Americo di Reguilain—resided, and sang the praises of his daughters, Constanza and Beatrice. Here also flourished Maestro Ferrari, a native of that city, who, as well as many other Italians (Alberto Guglielmo, Percivalle Doria, Alberto de' Marchesi Malaspina, &c.), sang in the Provençal language. No one acquired so great a reputation as Sordello of Mantua, who visited Provence for the purpose of making himself familiar with the language and poetry of the country. Only a few fragments of these Italian troubadours are extant; but the first attempts to compose in the Italian language are not to be looked for in Lombardy, where the vicinity to Provence did not allow a taste for native poetry to spring up. Besides, the Italian of Lombardy was the least agreeable to the ear. The Genoese and Venetians were too much occupied with commerce; the Florentines, disturbed by domestic factions, were ignorant of the spirit of chivalry, and the popes were absorbed in theology and the canon law, and strangers to the spirit of poetry. In Sicily only could Italian poetry develop itself, because the Sicilians, always a poetical people, spoke a dialect sufficiently soft to afford the means of graceful verse. Neither commerce nor scholastic disputes occupied their thoughts, and their beautiful climate invited them to repose, and to fill the moments of leisure with poetry. They could not draw the poets of Provence to their country so easily as the Lombards, nor could they themselves so easily visit that country of love and poetry; but enough of the Provençal songs reached them, to awaken them to similar attempts in their own language. They had also a court rich in every knightly and noble accomplishment. Frederic II. the German emperor, resided, for a time, in Palermo (from 1198—1212)—he who crowned a poet with his own hand, to whose court, as the old novelist relates, thronged troubadours, musicians, orators, artists, champions, and all persons of any kind of skill, from all countries, because of his munificence, and his courtesy, whose noble character is praised by Dante; but, not satisfied with hearing the verses of others, Frederic and his court composed poetry themselves, and productions of his, of his natural son Enzo, and his celebrated chancellor, Pietro delle Vigne, are still extant. One of the most distinguished Sicilian poets of that time was Ciuilo d'Alcamo, of whom we possess a song entirely Provençal in form and character. We have also the names and fragments of Jacopo da Lentino, surnamed *il Notajo*, of Guido, and Oddo delle Colonne, Ranieri, Ruggieri, and Inghilfredi of Palermo, of Arrigo Testa, Stefano, protonotary of Messina, and Monna Nina, who come down to the period of Dante, and were the cause that every thing composed in Italian was then called *Sicilian*. After the year 1300, Sicily gave no farther ankels to Italy; but the real founders of Italian poetry appear in Bologna, Florence, and other cities of Tuscany. The oldest known to us is, perhaps, Folcacchiero de' Folcacchieri, but the most important is Guido Guinicelli of Bologna. A number of poets appeared in Tuscany, whose names Crescimbeni enumerates, and of whom he gives specimens. In the thirteenth century, Guittone d'Arezzo (author of a book of poems and forty letters, interspersed with verses), Brunetto Latini (author of two poetical works—*Il Tesoretto* and *Il Pataffio*), Guido Cavalcanti

(author of a celebrated *canzone* and other poems), Ugolino Ubaldini (author of an excellent idyl in the form of irregular *canzoni*), and Dante di Majano (author of a book of poems), deserve mention; but we find hardly a poet of eminence in the other provinces. By the side of the amatory poets Jacopone da Todi stands alone, as a sacred poet. The forms of the early Italian poetry are borrowed from Arnaut Daniel, and other Provençals, and are, for the most part, the same which, in a more perfect state, characterize the later Italian poetry, viz., *canzoni*, sonnets, ballads, and *sestine*. With the Sicilians, we already find the *ottave* also. Its character is, even at this early period, decidedly marked. Its ruling spirit is love—an idealizing love, to which the spirit of Christianity contributed the tendency to adore and attribute perfection to the beloved object. Whether the new character which appears in all the productions of this time had its origin, as some maintain, in the spirit of Christianity, or only in certain feelings which sprang up at this time, and naturally connected themselves with Christianity, at least in appearance, we shall not here venture to decide, and refer the reader to the article *Chivalry*. It is certain that the modern spirit is essentially different from the ancient. (See *Classical*.) After this preparatory period of Italian poetry was passed, appeared the great Florentine, Dante Alighieri (born 1265). He left at once the trodden path, and stands without predecessor or follower among all the great names which ornament Italy. We do not speak of the form of his *Divina Commedia*, which, from its nature, could not but be unique, but of the peculiarity of his genius; but even his great poem, in which, as he says, heaven and earth assisted, and which cost the poet the study of years, is connected with love, his Beatrice being his guide in the highest spheres of heaven; and we should greatly misconceive the poet and his age, if we should suppose that this circumstance was merely intended to commemorate his early passion. The spirit of the age unavoidably led him to exhibit love as the great mover of the human soul. (See *Dante*.) As Dante's production is important in the history of the human mind and the progress of civilization, it is of equal importance in the history of Italian literature. Dante made the Italian dialect the lawful currency of literature. His intention to write his poem in Latin hexameters sufficiently shows in what a state he found the Italian language; how little the light play of graceful rhymes had developed it for his great object. Hence his apology for attempting so serious a subject in the *lingua volgare*. The enthusiasm for Dante's poem was so great, that in Florence, Bologna, and Pisa, professorships were early established for the explanation of his *Commedia*. In Florence, Boccaccio was the first who filled this chair. Of the commentators we shall mention, besides the later Landino, only Dante's own sons, Pietro and Jacopo, with Benvenuto of Imola, and Martino Paolo Nidobato. The archbishop of Milan, Giovanni Visconti, appointed two theologians, two philosophers, and two juris-consults of Florence, to undertake jointly the interpretation of the theology, philosophy, and jurisprudence of Dante. Besides Dante, there flourished several other poets, among whom Cino da Pistoia (q. v.) is the most distinguished. He excelled in tender love poems, in which he celebrated his mistress Selvaggia, and was the precursor of Petrarca, for whom he also prepared the language. Cecco d'Ascoli, also a contemporary of Dante, wrote a didactic poem, in five books, on physics, morals, and religion, under the title *Acerba* (properly *Acerbo* or *Acervo*). Francesco da Barberino composed his *Documenti d'Amore*, in which he treats of virtue and its rewards, in rude and irregular verses, and his

other poem, *Del Reggimento e de' Costumi delle Donne*, also a moral and didactic poem. Fazio degli Uberti wrote, at the same period, his *Dittamondo*—a system of astronomy and geography in verse, in which Dante served him as a model. Without dwelling on the less important lyrical poets, Benuccio Salimbeni, Bindo Bonichi, Antonio da Ferrara, Francesco degli Albizzi, Sennuccio del Bene, a friend of Petrarca, we come immediately to the latter. (See *Petrarca*.) His love did not, like Dante's, inspire the idea of one great poem, treating of all the acts and efforts of man, and his religious conceptions were still more strongly the ideal of love. His sonnets and *canzoni* are very differently esteemed; but if they appear to many readers of our age frequently overstrained, and sometimes devoid of the spirit and fullness of genuine poetry, to others they are a model of lyrical excellence; and his influence on the language of Italian poetry has been very great, rendering it softer and more flexible than Dante had left it. Petrarca was an excellent scholar, and well acquainted with Roman elegance, and he elevated his language to the greatest purity, beauty, and melody. His followers are innumerable. Among them, in the fourteenth century, are the two Buonaccorsi da Montemagno, and Franco Sacchetti, the writer of *novelle*. The glory which Petrarca had acquired in a species of poetry easy in itself, and so consonant with the taste which his nation has preserved even to the present time, and to the spirit of the age, was too enticing; but the Petrarchists forgot that it is the spirit of their master which gained him his fame, and not merely the harmonious sound of his musical rhymes; and they poured forth innumerable poems, a comparison of which with those of Petrarca could only raise him still higher. Petrarca not only wrote lyrical poems, but in his *capitoli*, or triumphs, approaches the didactic. He composed also Latin poems, eclogues, and an epic, *Africa*, celebrating his favourite hero, Scipio, the latter of which obtained him the poetic laurel, in the capitol, in Rome, and which—so easily do great poets mistake their own merits—he himself valued most, whilst he considered his lyrical poems of little value, and in his old age wished that he had not written them. Not less famous than Petrarca is his friend Boccaccio. (See the article *Boccaccio* for an account of his great service in the formation of Italian prose.) The satirical sonnets of Pucci, the didactic essay on agriculture by the Bolognese Paganino Bonafede, and the Four Kingdoms of Love, Satan, Vice, and Virtue, by his countryman Frederigo Frezzi, under the title *Quadrivregno*, an unsuccessful imitation of Dante, belong also to this period. In the fifteenth century, Giusto de' Conti first meets us—an imitator of Petrarca. In his sonnets he celebrates the beautiful hand of his mistress, on which account the whole collection is called *La Bella Mano*. About 1413, the barber Burchiello, at Florence, acquired no little reputation by his peculiar, but, for us, unintelligible sonnets. The attempt of the painter and architect, Leon Battista Alberti (somewhat later, under Cosmo de' Medici), to compose hexameters and pentameters in Italian, is worthy of mention. Lorenzo de' Medici, after the death of his grandfather (1464), the Pericles of the Florentine republic, was inspired by his passion for Lucretia Donati, a noble Florentine lady, to imitate Petrarca; yet he did it with independence. He was the pupil of the Platonist Marsiglio Ficino. Besides sonnets and *canzoni*, we have *capitoli*, *stanze*, *terzine*, and carnival songs, by him. His *Symposium*, or the Drinkers (*Boni*), a sportive imitation of Dante, describes three journeys into a wine cellar. The most distinguished of the contemporaneous poets was Angelo Ambrogini, called *Policiano*, from the small village

Montepulciano, who is celebrated also as a scholar and philosopher. Besides a dramatic poem, *Orfeo*, there is a fragment by him, in beautiful stanzas, in praise of Julian of Medici, on occasion of a tournament, exhibited by the brothers, at Florence. A friend of his was the graceful amatory poet Girolamo Benivieni. Of the three brothers Pulci, Bernardo wrote two elegies, a poem on the passion of Christ, and was the first who translated the eclogues of Virgil into Italian. Luca was the author of the *Heroides*, a poem in *ottave rime*, in which he celebrated, earlier, but not less beautifully than Poliziano, a tournament of Lorenzo of Medici, a pastoral, also in *ottave rime*, entitled *Driadeo d'Amore*, and an epic poem of chivalry, *Ciriffo Calaneo*, which in itself is of little value, and was left incomplete (Bernardo Giambullari finished it after the death of the poet), but which is remarkable as the commencement of those ironical and serious poems of chivalry, which, with the decline of chivalry and the poetry of the middle ages, became natural, and, we might almost say, necessary to the poetical spirit of the Italians. Luigi, the most celebrated of the three, owes his fame not to the whimsical sonnets in which he and his friend, Matteo Franco, held each other up to the laughter of Lorenzo and his guests (*ofers* in the most indecent language), nor to his *Beca da Dicomano*, &c., but to his *Morgante Maggiore*, by which he became the predecessor of Ariosto, who, however, surpassed him as much as he himself surpassed the first rude attempts of the fourteenth and fifteenth centuries in this department, of which the *Buovo d'Antona*, *La Spagna Historiata*, and *La Regina Ancroya*, are the most known. The *Membrano* of Francesco Cieco da Ferrara, which is not unworthy to stand by the side of the *Morgante*, served to amuse the Gonzaga, at Mantua; but a more immediate predecessor of Ariosto was Matteo Maria Boiardo, author of the *Orlando Innamorato*, which at first was not much relished by the Italians, on account of its gravity, as they had already become too fond of irony in these epics of chivalry; so much so, that Boiardo, continued by Niccolò degli Agostini, was entirely recast by Domenichi, and, at a later period, by Berni. Contemporaries with these epic poets were the satirist Berni, Belliccioni, and numberless Petrarchists, as Francesco Cei, Gasparo Visconti, Agostino Staccoli d'Urbino, Serafino d'Aquila, Antonio Tebaldeo, Bernardo Accolti, a celebrated improvisatore, who assumed the modest surname *L'Unico*, a Neapolitan under the name of *Naturno*, a Florentine, Cristoforo, under the name of *L'Albasimo*, &c. Antonio Fregueso, surnamed *Filareta*, wrote a moral erotic poem, *La Cerce Biana*, of moderate value, with *Selce*, and gay and melancholy *capitoli*. Gian Filoteo Achillini deserves to be mentioned, on account of his scientific-moral poems, *Il Viridario* and *Il Fedele*, and Cornazzano dal Varesino, for his poem on the art of war, entitled *De Re Militari*. Distinguished as female poets of this century are, Battista Montefeltro, wife to Galeazzo Malaspina, her niece Constanza, Bianca of Este, Damigella Trivulzi, Cassandra Fedele, and the two Isotta. The sixteenth century, the period of Italian poetry, in which the princes of Italy, and particularly the popes, extended the most munificent patronage to poetry and the arts, begins with the *Orlando* and other poems of the admirable Ariosto. Giovanni Giorgio Trissino attempted, without success, the serious epic. His work is dry and cold. Giovanni Rucellai displays much tenderness and feeling in his didactic poem *Le Api*. Luigi Alamanni, author of a didactic poem on agriculture (*La Coltivazione*, a romantic epic, *Girone il Cortese*, and *Ateneide*, a modern *Iliad*, on the whole a failure), belongs rather

to poets of the second rank. Sannazzaro distinguished himself in his *Arcadia*, and in his lyric poems, by delicacy of feeling and beauty of expression. Berni became the creator of a new department. Among the Petrarchists of this age are Bembo, Castiglione, and Molza. Lodovico Domenichi published, in 1559, the poems of fifty noble ladies. Among these was Vittoria Colonna, wife of Fernando d'Avala, marquis of Pescara. (Respecting Aretino, equally known for genius and licentiousness, see *Aretino*.) Bernardo Tasso, in his epic, and still more in his lyric poems, appears as an excellent poet, but was surpassed by his son Torquato Tasso. (See *Tasso*.) Guarini displays much grace in his lyrics (madrigals and sonnets), but he owes his fame to his *Pastor Fido*. Gabriello Chiabrera was distinguished as a lyric poet. He also wrote several epic poems and pastoral dramas. The learned father Bernardino Baldi published, besides sonnets and *canzoni*, a hundred apologies in prose. Attempts had already been made in the *Æsopic* fable by Cesare Pavesi, under the name of *Targa*, and by Giammaria Verdzotti, but with less success. Teofilo Folengi, more known under the name of *Merlin Coccajo*, must be mentioned as the inventor of macaronic poetry. As early as the second half of the sixteenth century, the corruption of taste had begun, and continually increased, so that the seventeenth century produced but very few works which can be considered as exceptions. We should mention, however, Marino (q. v.), who, as it were, founded his own school, from which proceeded Claudio Achillini, Girolamo Preti, Casoni and Antonio Bruni, who were his most ardent admirers. Alessandro Tassoni is known as the author of *La Secchia Rapita*, a comic and satiric epic. Francesco Bracciolini, who had imitated Tasso, in his *Croce Racquistato*, with no great success, by his *Scherzo degli Dei*, disputed with Tassoni the honour of the invention of the mock-heroic, but does not equal him in grace and ingenuity. Two later mock-heroic poems—*Il Malmantile Racquistato*, by Lorenzo Lippi, and *Il Torracchione Desolato*, by Paolo Minucci—have no other merit than the purity of their Tuscan language. The works of Carlo de' Dottori, Bartolomeo Bocchini, Cesari Caporali, are not of distinguished merit. Filicaja's lyrical poems glow with patriotic feeling, and a noble elevation, which will always render him popular. Count Fulvio Testi was the Horace of his nation, but his epic productions were mere fragments. The caustic satires of the painter Salvator Rosa are not to be passed over in silence, amidst the general barrenness of Italian poetry, about the middle of the seventeenth century. The residence of Christina, queen of Sweden, in Rome, and her predilection for the classic muse, served to banish from the circle of poets, who assembled round her, the Marinistic exaggeration, and to substitute for it a frigid correctness. Her conversion to the Catholic faith also attracted more attention to sacred poetry than it had previously received in Italy; but no poet of her circle merits particular notice. Deserving of mention is Niccolò Fortiguerra, author of the *Riccardetto*, the last epic of chivalry. Nolli, whose songs and odes were popular, translated Milton's *Paradise Lost*, and was the first who made his countrymen acquainted with English literature, whilst, at the same time, the French taste began to prevail, which exercised a decided influence, particularly on the dramatic literature of Italy. Fewer candidates now appear on the Italian Parnassus. The abbat Carlo Innocenzio Frugoni, among other poetical productions (mostly frigid occasional pieces), composed sonnets and *canzoni*, of which the sportive ones are praised. There is a successful translation of the *Psalms* by Mattei. The *Arte Rappresentativa* (the

Histrionic Art) is a didactic poem worthy of mention, by Lodovico Riccoboni, who raised the character of the Italian theatre at Paris. Francesco Algarotti, the companion of Frederic the Great, belonging to the French school, in his odes, poetic epistles, and translations, exhibited the pleasing ease, but, at the same time, the coldness of the French. Roberti and Pignotti wrote *Æsopic* fables with originality and elegance. Twenty poets were united in the composition of a comic poem, under the title *Bertoldo, Bertoldino*, and *Cacasenno*. Luigi Savioli sung of love in the style of Anacreon. As erotic and lyric poets, must be mentioned with him Gherardo de' Rossi and Giovanni Fantoni, called, among the Arcadians (see *Arcadia*), *Labindo*. A pleasing enthusiasm pervades the poetry of Ippolito Pindemonti; and, among the productions of his friend Aurelio Bertola of Rimini, the fables rank the highest. Clem. Bondi is pleasing, but without creative power. Giuseppe Parini, who imitated Pope's Rape of the Lock, displays true poetic elevation and fine feeling. Onofrio Menzoni, who is not without poetic originality, confined himself almost entirely to sacred poems. Alfieri was distinguished for his satires, lyric poems, his *Etruria Vendicata*, and his dramatic compositions, translations, &c. (See *Alfieri*.) The abbat Giambattista Casti was distinguished for elegance, wit, and humour. His *Animali Parlanti*, a mock-heroic poem, is rich in satiric and humorous traits. His *Novelle Galanti* are often indecent. The late Vincenzo Monti is pronounced unanimously to have been the greatest among the recent poets of Italy. Besides his dramatic compositions, his most celebrated poem is his *Bassavigliana*, in which he imitates Dante. But who can enumerate the host which now lays claim to the poetic laurel, particularly since the souvenirs flourish in Italy also, and offer so fine a field for sonnets, of which there is hardly an educated Italian who has not composed some? The grave character which the times are assuming will perhaps put an end to these elegant trifles, whose abundance cannot be considered favourable to an elevated tone, either in literature or the fine arts. The souvenirs have already declined in Germany, where they originated. The latest epic attempts have not been successful. The *Italiade* and *S. Benedetto*, by A. M. Ricci, *Mosè*, by Robiola, the *Moabitide*, by Franchi di Pont, were inferior to the specimens which have appeared of Palomba's *Medoro Coronato*. More interest has been excited by the tragedies, the authors of which, however, are restrained by their party views of the romantic and classical. Fabbri of Cesena, Marsini, the duke of Vendigriano, follow the example of Alfieri, respecting whose poetical system, see the article *Alfieri*. Ugo Foscolo's *Ricciarda* (*Londra*, i. e. Turin, 1820) was intended to introduce a taste for the romantic style into Italy; but it is already forgotten. Manzoni, a cultivator of this kind of poetry, or of what the Italians understand by this name, has been more successful. Goethe praised Manzoni's *Conte di Carmagnola* (Milan, 1820) highly. Pindemonti, Maffei, and Nicolini, however, are placed higher than Manzoni by all parties. The productions in the comic department are poor; they appear, at least to other nations, heavy and dragging, and the *Commedia dell'Arte* (see *Drama*) is not considered worthy of notice by the high classes; yet its strong humour might perhaps please an unprejudiced mind more than the writings of Nota, Giraud, and Panzadoro. Barbieri's *Nuova Raccolta Teatrale, ossia Repertorio ad Uso de' Teatri Italiani* (Milan, 1820), and Marchisio's *Opera Teatrale* (Milan, 1820), endeavour to supply the want of native productions by translations of French and German works—proof enough that the

natural gayety of the south, formerly the home of pleasure, is departing. How can it be otherwise under the Austrian sceptre? Our limits do not permit us to mention the writers of sonnets and operas. Trite subjects are brought up under forms a thousand times repeated, and thus the miracle, that Sgrizzi can astonish his audience with improvised tragedies is partly explained. (See *Improvvisatori*.) The treasure of the *novelle*, of which Shakspeare so happily made use, lies before the Italian poets, untouched, and seems even to be little known to the Italian public at large. Theatres like those of S. Carlo at Naples, Della Scala at Milan, Pergola at Florence, where whole regiments might appear on the stage, do not afford much reason to hope for the restoration of dramatic excellence. The historical novel, which Sir Walter Scott has rendered so popular with all nations, has been attempted in Italy, as in Livati's *I viaggi di Fr. Petrarca* (Milan, 1820), Grossi's *Il degondé*, Manzoni's *Promessi Sposi*, and the *Monaca di Monza*. The history of Italian poetry, particularly of the older periods, is to be found in the works of Crescimbeni, Quadrio, Tiraboschi, and also in Ginguené's *Histoire Littéraire d'Italie*, Sismondi's work *De la Littérature du Midi*, and in Bouterwek (q. v.) the two last of which works come down to our own times.

*Italian Theatre.* The political state of Italy, and the easy, careless life of the people, in their mild and beautiful climate, have co-operated in causing the dramatic literature of Italy to remain in a very backward state. It was revived, as has been shown in the article *Drama*, earlier among the Italians than among other nations, because they had the model of the ancient drama before their eyes; but this very circumstance was one reason why a national drama was not formed in Italy. The modern Italian, generally speaking, has not that reflecting turn of mind, which is necessary for the composition and enjoyment of a truly good drama; nor has sufficient liberty existed for centuries in Italy to afford a fair field for dramatic talent. If it be objected that the Spanish drama attained its perfection under the stern sway of an absolute government, it may be answered, that the higher drama, with the Spaniards, is of a religious cast—a consequence of that religious gloom which belongs to the Spanish character, but which the gay Italian does not feel. The extemporaneous mask, which is such a favourite with the lower classes of Italy, is condemned for this very reason by the higher classes; and whilst the people in general relish nothing but the *commedia dell' arte* (see *Drama*), the higher classes care only for the opera. The *drama*, therefore, properly so called, does not appear like a natural part of Italian literature, and we trust it will not be considered an arbitrary division, if we treat the Italian drama separately from the body of Italian literature. The dramatic writers of this country started with so close an imitation of the ancients, that no Italian, down to the last quarter of the fifteenth century, wrote a tragedy in any language except Latin; and the *Orfeo* of Angelo Poliziano, of that time, is a series of lyrical poems dramatically attached to each other—a tragedy merely in name. The *Sofonisbe* of Trissino imitates in every point the ancient model, even to retaining the chorus; it is not without merit, but, on the whole, is a pedantic work; yet, in the time of Leo X., in 1516, it was received with so much applause, as to be represented in Rome with great pomp. Ruccellai (1525) bears the same marks of imitation and want of poetical invention; even Tasso's *Torrismondo* (about 1595), though particular passages remind us of his immortal poems, is stamped with the same character. Amidst the minute and anxious

observance of the rules of Aristotle, closely followed by many Italian writers of tragedies not worthy of mention, count Prospero Buonacelli deserves credit for venturing to omit the chorus; on the other hand, the lawyer Vincenzo Gravina once more attempted to show that imitation of Seneca was the only way to tragic perfection. After Mortello, in the beginning of the eighteenth century, had finally attempted to improve the Italian drama by the imitation of Racine and Corneille (he even endeavoured to introduce the French Alexandrine), Maffei, in his *Merope*, aimed at a middle course, and, without imitating either, to unite the excellencies of Seneca and of the French theatre. In this absence of real tragedies, the serious operas, the musical dramas of Metastasio (born 1738), may be properly mentioned. Their time had been settled by the attempts of Apostolo Zeno. Without marked character or free play of imagination, they always preserve the decorum of the French theatre; but in elegance and melody of language, and in musical softness of expression for the common places of passion, particularly of love, they are unrivalled. Alfieri, who wrote towards the end of the last century, is, throughout his writings, a contrast to Metastasio. (See *Alfieri*.) He does not satisfy a German or an Englishman in his conception of dramatic excellence. Among his followers are Vincenzo Monti of Ferrara, Alessandro Pelopi of Bologna, and particularly Giambattista Niccolini of Florence, whose *Polyxena* received a prize in 1811. The pastoral dramas of Tasso and Guarini, viz., the *Aminta* of the former, and the *Pastor Fido* of the latter, form a novel kind of dramatic poetry. They entirely eclipsed those of Niccolò Coreggio, Agostino Reccati, Cinthio Giraldi, Agostino Argenti, and Buonarelli. Tasso succeeded in uniting the sweetest tones of Theocritus, Anacreon, and of the eclogues of Virgil, without injuring his originality. In comedy, the Italians also began with a close imitation of the ancients, not, however, of the comedy of Aristophanes, but of the Romans, Plautus and the calm Terence. These productions were called, in contradistinction from the extemporaneous comedy, *commedie erudite* (learned comedies). The comedies of Ariosto and the *Clizia* of Machiavelli exhibit this imitation. The other comedies of the latter are altogether Florentine in their character, but we must admit that they are deficient in that elevated tone of comedy, which we admire in Shakspeare. We mention Tasso's *Gli Intrighi d'Amore* only on account of the author's name. The *Tancia*, by the younger Michael Angelo Buonarroti (1620), is one of the most remarkable Italian comedies, on account of the Florentine nationality so well portrayed in it. Goldoni endeavoured to put an end to the *commedie dell' arte*, by his grave moralizing comedies. On the other hand, Gombi strove to save the extemporaneous comedy, by elevating its character. In comedies, the subjects of which were taken from fairy tales, and in tragi-comedies, the materials of which were from Calderon and Moreto, without, however, having their poetical execution or genius, he only wrote the chief parts, and these in very easy verses. In the less important parts, which were intended for the standing masks, he was satisfied with indicating merely the leading ideas, leaving the execution to the talent of the actor. He remained without a follower. Among the latest writers of comedies, we may mention Albergati, whose *Prisoner* received a prize at Parma, and who wrote a number of agreeable farces; the Venetian Francesco Antonio Avelloni, surnamed *il Poetino*, an imitator of the French; Antonio Simone Sograsi; the Neapolitan Guastetti; the abbot Chari; the Piedmontese Camillo Federici; the Roman Gerardo de' Rossi; count Giraud; Giovanni Fu-

dramatic, &c. (See *Italian Poetry*.) Augustus William von Schlegel says (vol. ii. p. 68, of his *Dramatische Vorlesungen*), "We think it not saying too much to assert, that dramatic poetry, as well as the histrionic art, is in the lowest state in Italy. The foundation of a national theatre has never yet been laid, and, without a total reform in principles, there is no prospect that it ever will be."

**Italian Art.** The art of painting was early introduced both into Italy and Germany by Greek masters; but the diversities of national character, climate, and religion, produced different results in the two countries. A glowing imagination, an easy life, an innate sense for the beautiful, enthusiastic poetry, the constant sight of nature in her fairest forms, and the contemplation of the masterpieces of ancient art, occasioned painting, in Italy, to unfold with great magnificence; while, in Germany, the ancient painters loved rather to dwell on the inward life and character. They were poets and philosophers, who selected colours instead of words. The Italians have therefore remained inimitable in the ideal of this art, as the Greeks in statuary. The twelfth century is generally taken as the period of the beginning of the history of painting in Italy; but, even before that time, it had been the scene of the labours of Greek and Byzantine artists. During the pontificate of Leo the Great, in the year 441, a large picture in mosaic was executed in the Basilica of St Paul, on the road to Ostia, and the portraits of the forty-two first bishops, which are seen in the same church, date their origin from the same time. Mosaic and encaustic painting was then the prevalent mode. Painting in distemper was afterwards introduced. About the end of the sixth century, there were many paintings, which were not believed to be the work of mortal hands, but were attributed to angels or blessed spirits. To this class belongs one of the most famous representations of the Saviour, in wood, at Rome, called *Αχιλλεύς*, of which a sight can be obtained only with difficulty, in the *sanctum sanctorum*. Whether the evangelist Luke, whom painters afterwards chose for their patron saint, was himself a painter, has been the subject of much controversy. In Rome, especially, the *madonnas* in Sta. Maria Maggiore, Sta. Maria del Popolo, Sta. Maria in Araceli, and the one in the neighbouring *Grutta Ferrata*, have been ascribed to the pencil of the evangelist. In the eighth century, painting on glass, mosaic on a ground of gold, and painting in enamel, were zealously prosecuted in Italy. There were already many native artists. One of the oldest monuments of art is the celebrated Christ on the Cross, in the Trinity church at Florence, which existed there as early as 1003. About 1200, a Greek artist, Theophanes, founded a school of painting in Venice. The genuine Italian style first bloomed, however, in Florence, and may be treated under three leading periods: 1. from Cimabue to Raphael; 2. from Raphael to the Caracci; 3. from the Caracci to the present time.

**First Period.** The art was first pursued with zeal in Pisa. Giotto Pisano, Guido of Sienna, Andr. Insi and Buffalmacco precede Cimabue, who was born at Florence, in 1240. This artist, who was regarded as a prodigy by his contemporaries, first introduced more correct proportions, and gave his figures more life and expression. His scholar Giotto excelled him even in these respects, and exhibited a grace hitherto unknown. He was the friend of Dante and Petrarch, and practised, with equal success, historical painting, mosaic, sculpture, architecture, and portrait and miniature painting. He first attempted foreshortening and a natural disposition of drapery, but his style, nevertheless, remained dry and stiff. Boniface VIII.

invited him to Rome, where he painted the still celebrated Navicella. He was followed by Gaddi, Stefano, Maso, and Simone Memmi, who painted the celebrated portraits of Petrarch and Laura. But Masaccio first dispelled the darkness of the middle ages, and a brighter dawn illumined the art. The Florentine republic, in the beginning of the fifteenth century, had attained the summit of its splendour. Cosmo of Medici patronized all the arts and sciences; Brunelleschi then built the dome of the cathedral; Lorenzo Ghiberti cast the famous doors of the baptistery in bronze; and Donatello was to statuary what Masaccio was to painting. Masaccio's real name was Tommaso Guidi. He was born at St Giovanni, in Val d'Arno, in the year 1402. His paintings have keeping, character, and spirit. His scholars first began to paint in oil, but only upon wooden tablets or upon walls, coated with plaster of Paris. Canvas was not used till long after. Paolo Uccelli laid the foundation for the study of perspective. Luca Signorelli, who first studied anatomy, and Domenico Ghirlandaio, who combined noble forms and expression with a knowledge of perspective, and abolished the excessive use of gilding, were distinguished in their profession. The elevated mind of Leonardo da Vinci (see *Vinci*), who was born in 1444, and died 1519, and who was a master in all the arts and sciences, infused so much philosophy and feeling into the art, that, by his instrumentality, it quickly reached maturity. From him the Florentine school acquired that grave, contemplative, and almost melancholy character, to which it originally leaned, and which it afterwards united with the boldness and gigantic energy of Michael Angelo. The Roman school already enumerated among its founders the miniature painter Oderigi, who died in 1300. He embellished manuscripts with small figures. Guido Palmerucci, Pietro Cavallini and Gentile da Fabriano were his most distinguished successors. Almost all the painters of this time were accustomed to annex inscriptions to their pictures: the annunciation to the virgin Mary was their favourite subject. Perugia was the principal seat of the Roman school. As early as the thirteenth century, there was a society of painters there. Pietro Vanucci, called *Perugino* (who was born 1446, died 1524), first introduced more grace and nobler forms into this school, whose character acquired from him something intellectual, noble, simply pious and natural, which always remained peculiar to the Roman school. Perugino's great scholar, Raphael, soon surpassed all former masters, and banished their poverty, stiffness, and dryness of style. Taste came into Venice from the East. Andr. Murano and Vittore Carpaccio are among the earliest artists of that city. Giovanni and Gentile Bellini are the most distinguished painters of the earlier Venetian school. The former was born 1424, and died 1514. The latter laboured some time in Constantinople under the reign of Mohammed II. They introduced the glowing colours of the East; their style was simple and pure, without rising to the ideal. Andr. Mantegna (born at Padua, in 1431, died 1506) was the first to study the ancient models. Padua was the principal seat of the Venetian school. Mantegna afterwards transferred it to Mantua, and his style formed the transition to the Lombard school. Schools of painting flourished in Verona, Bassano, and Brescia. Giovanni of Udine (who was so distinguished by his faithful imitation of nature in secondary things, that he painted for Raphael the garlands around his pictures in the Farnesina), Pellegrino, and Pordenone, were the most able predecessors of the two great masters of the Venetian school, Giorgione and Titian. No capital city served as the central point of the Lombard school: Bologna subsequently became the

centre. Imola, Conto, Ferrara, Modena, Reggio, Parma, Mantua, and Milan were afterwards considered the seats of this school. Galasio, who lived about 1220, Alighieri, Alighisi, Cosimo Tura, Ercole Grandi, and especially Dosso Dossi (born 1479, died 1560), were the principal painters of Ferrara. The last, a friend of Ariosto, possesses a remarkable grandeur of style, united with a richness of colouring which may bear comparison with that of Titian. Bramante, (born 1444, died 1514), who was likewise a great architect, Lippo Dalmasi, and especially Francesco Raibolini (born 1450), called *Francesco Francia*, were highly distinguished among the Bolognese masters. The latter, who was marked by a tender religious expression and uncommon industry, had the greatest veneration for Raphael. It is asserted that, at the sight of the St Cecilia of this master, he was so struck with the impossibility of attaining the same perfection, that he fell into a deep melancholy, and soon after died. Here also belongs the charming Innocenzo da Imola. But all these were far surpassed by the incomparable Antonio Allegri da Correggio, who, in fact, first founded the character of the Lombard school, so distinguished for harmony of colours, expression replete with feeling, and genuine grace.

*Second Period.* We now come to the greatest masters of any age, who, almost at the same time, as heads of the four schools, carried every branch of the art to the highest perfection. In Italy, they and their scholars are called *Cinquecentisti*, from the century in which they flourished. This period of perfection passed away rapidly, and soon required the violent restoration, with which the third period commences. After Leonardo da Vinci, in the Florentine school, had settled the proportions of figures, and the rules of perspective and of light and shade, and his scholars, Luini (who united Raphael's style with that of his master), Salaino and Melzo, besides the admirable Baccio della Porta, who is famous under the name of *Fra Bartolommeo*, (born 1469), and whose works are distinguished for elevated conception, warmth of devotion, and glowing colours, had done much for the art, and after the gentle and feeling Andrea del Sarto (born 1488, died 1530), the intellectual Balthasar Peruzzi and the gay Razzi had made this school distinguished, arose the most extraordinary of all masters, Michael Angelo Buonarroti (born 1474, died 1564). His gigantic mind grappled, with equal power, statuary, architecture, and painting. His fire of composition, his knowledge of anatomy, the boldness of his attitudes and foreshortenings, leave him without a rival; but, as a model, he was detrimental to the art, because his imitators necessarily fell into exaggeration and contempt of a simple style. In grandeur, his fresco painting, the Last Judgment, in the Sistine chapel at Rome, is inimitable. Beauty was never so much his object, as power and sublimity, especially since, in the former, he could never equal Raphael, but in the latter stood alone. Dante was his favourite poet. In his later years, the erection of St Peter's church almost entirely engrossed his thoughts. Rosso de' Rossi, Daniel of Volterra, Salvati, Angelo Bronzino, Alessandro Allori, and many others, were his scholars and imitators. In 1580, Ludov. Cigoli and Greg. Paganini began to awaken a new spirit. They returned to nature, and sought to create a better taste in the *chiaro oscuro*. Domenico Passignani, Cristoforo Allori, and Comodi were their followers. If we turn our attention to the Roman school, we find at its head the first of artists—Raphael Sanzio da Urbino (born 1483, died 1520.) His genius showed itself as elevated in his fresco paintings, in the *stanze* and *loggie* of the Vatican (the former of which contain the School of Athens, the Parnassus,

and the Conflagration of the Borgo, while the latter contain scriptural scenes, from the creation through the whole Old Testament), as it appears lively, spiritual and original in the frescos of the Farnesina (representing the life of Psyche). No less superior are his oil paintings, of which we shall only mention his *madonnas*, celebrated throughout the world, especially the *Madonna del Sisto* (in the Dresden gallery), the *Madonna della Sedia* (in Florence), *Madonna della Pace* (in Madrid), *Maria Guardiana* (in Paris), *Madonna di Foligno* (in Rome), his St Cecilia (in Bologna), and his last work, the *Tomb* of Christ. His scholars and successors—the bold Giulio Romano (born 1492, died 1546), the more gloomy Franc. Penni il Fattore (born 1500, died 1528), the lofty Bartolommeo Rameneta, surnamed *Bagnacavallo*, Pierino del Vaga, Pseudo da Caravaggio, Gemigniani, Benvenuto Tisi, called *Garofolo*, and many others—were skilful masters, but they forsook the path of their great pattern, and degenerated into mannerism. Federico Barrocci (born 1528, died 1612) endeavoured to counteract this tendency. In spirit, he belonged to the Lombard school, as he aimed at the grace of Correggio. He possesses an uncommon degree of grace and expression. With his scholars Francesco Vanni, Pellegrini, and the brothers Zuccheri, he infused a new life into the Roman school, though the latter produced piccing rather than great works, and fell into mannerism. Muziano was distinguished in landscape painting, and Nogari, Pulzone, and Faccibelli in portrait painting. At the head of the Venetian school, we find the two excellent colourists Giorgione Barbarelli di Castelfranco (born 1477, died 1511) and Tiziano Vercelli (born 1477, died 1576). The portraits of the former are celebrated for their warmth and truth. The latter was great in all the departments of art, inimitable in the disposition of his compositions, excellent as an historical and portrait painter, and the first great landscape painter. Even at an extreme old age, his powers were unimpaired. Ariosto and Aretino were friends of the gay, happy Titian. He executed many works for the Spanish kings. Some of his most famous works are the altar piece of St Pietro Martire, his pictures of *Venus*, *Bacchanal*, and his *Children Playing*, in Madrid, *Cristo della Moneta*, &c. He first understood the art of painting with transparent colours. In groups he selected the form of a bunch of grapes for a model. His successors—Sebastiano del Piombo, Palma Vecchio, Lorenzo Lotto, Paris Bordone, Pordenone—are distinguished, especially in colouring. Schiavone, whose *chiaro oscuro* and richness of colour are truly remarkable; Giacomo da Ponte, called *Bassano*, who imitated reality, even in common things, to deception, and who was the head of a whole family of painters; the ardent, ardent Robusti, called *Il Tintoretto* (born 1512, died 1596), whom Titian, through jealousy, dismissed from his school; the fantastic, splendid Paul Veronese (born 1532, died 1588), who painted boldly and brilliantly with a free pencil, but neglected all propriety of costume, and frequently mingled masks in his paintings, and the Veronese Cagliari, were unimpaired of the Venetian school. It likewise degenerated, and its mannerists were worse than those of the other schools, because they did not study the antique as the ideal. At the head of the Lombard school, we find the charming Antonio Allegri, called *Correggio* (born 1494, died 1534), whose works are full of feeling. (See *Correggio*.) His successors and scholars were Francesco Rondani, Gatti, Leito Orsi, and especially Francesco Mazzola il Parmegiano (born 1533, died 1540). This artist possessed much fire, and a peculiar grace, which frequently over-

on mannerism. Gaudenzio Ferrari, and many others, are the ornaments of the Milanese school. In landscape painting, Lavizzario was called the *Titian of Milan*. The famous Sofonisba Angosciola (born 1530), of Cremona, was highly distinguished in music and painting. As an excellent portrait-painter, she was invited to Madrid, where she painted don Carlos and the whole royal family, and gave instruction to queen Elisabeth. Van Dyke declared that he had learned more from the conversation of this woman, when she was blind from age, than he had from the study of the masters. She died in 1620. Lavinia Fontana, Artemisia Gentileschi, Maria Robusti, and Elis Sirani were celebrated female artists of this time. Camillo and Giulio Procaccino were distinguished for strength of imagination and excellent colouring. In Bologna, we find Bagnacavallo, a distinguished artist of this period, whom we have already mentioned as one of Raphael's scholars. He flourished about 1542. Francesco Primaticcio (born 1490, died 1570), Niccolò dell'Abbate, Pellegrino Tibaldi, Passarotti, and Fontana were very able Bolognese artists.

*Third Period.* It begins with the age of the three Carracci. These excellent artists endeavoured to restore a pure style, and, by the combined study of the ancient masters of nature and science, to give a new splendour to the degraded art. Their influence was powerful. The division into the four principal schools now ceases, and we find but two principal divisions—the followers of the Carracci, who are called *eclectics*, and the followers of Michael Angelo Caravaggio, who are called *naturalists*. Lodovico Carracci (born 1555, died 1619) was the uncle of the two brothers Agostino (born 1558, died 1601) and Annibale (born 1560, died 1609). Lodovico was quiet, contemplative, soft, and serious. His passionate teachers, Fontana and Tintoretto, at first denied him any talent: he studied therefore more zealously, and acquired the deepest views as an artist. Agostino united uncommon sagacity and the most extensive knowledge with a noble character. His brother Annibale, who made extraordinary progress in the art, under Lodovico's direction, became jealous of Agostino. The disputes between the two brothers never ceased, and the offended Agostino devoted himself chiefly to the art of engraving. The attacks of their enemies first united them, and they founded together a great academy. The brothers were invited to Rome to paint the gallery of the duke of Farnese. They soon disagreed, and Agostino retired, and left the work to his fiery brother. Annibale completed the undertaking with honour, but was shamefully cheated of the greatest part of his pay. Deeply mortified, he sought to divert his mind by new labours and a journey to Naples; but the hostility which he there experienced, hastened his death. Meanwhile, the quiet Lodovico finished, with the aid of his scholars, one of the greatest works—the famous *portrait of St Michael in Bosco*, in Bologna, on which are represented seven fine paintings, from the legends of St Benedict and St Cecilia. The last of the labours of this great master was the *Annunciation to Mary*, represented in two colossal figures, in the cathedral of Bologna. The angel is clothed in a light dress, and, by an unhappy distribution of drapery, his right foot seems to stand where his left belongs, and *vice versa*. Near at hand, this is not observed; but, as soon as the large scaffold was removed, Lodovico saw the fault, which gave occasion to the bitterest criticisms from his enemies. The design which he suffered on this occasion brought him to the grave. The scholars of the Carracci are numberless. The most famous endeavoured to imitate the grace of Correggio with the grandeur of

the Roman masters. Cesare Aretusi was distinguished for the most faithful copies of Correggio and Guido Reni (born at Bologna, 1575, died 1642), especially for the ideal beauty of his heads, the loveliness of his infant figures, and the uncommon facility of his pencil. His fresco representing *Aurora*, in the palace Borghese, and his oil painting, the *Ascension of Mary*, in Munich, are well known. Francesco Albani (born 1578 at Bologna, died 1660) lived in constant rivalry with Guido. He produced many large church paintings, but was most celebrated for the indescribable charm with which he represented, on a smaller scale, lovely subjects from mythology, and especially groups of Cupids. His paintings in the Verospi gallery, and his *Four Elements*, which he painted for the Borghese family, gained him universal reputation. The background of his landscapes is excellent. All his works breathe serenity, pleasure, and grace. The third great contemporary of those already mentioned, Domenico Zampieri, called *Domenichino* (born 1581, died 1641), was at first little esteemed by them, on account of his great modesty and timidity. Thrice were prizes awarded by Lodovico to drawings, the author of which no one could discover. At last Agostino made inquiries, and the young Domenichino timidly confessed that the drawings were his. His industry and perseverance rendered him the favourite of his master. His works evince the most thorough knowledge, and are rich in expression of character, in force, and truth. His *Communion of St Jerome*, his *Martyrdom of St Agnes*, and his fresco in the Grotta Ferrata, are immortal masterpieces. He was always remarkable for his timidity. He was invited to Naples, but was there persecuted and tormented by the painters; and it is even suspected that he was poisoned. Giovanni Lanfranco (born at Parma, 1580, died 1647) was especially distinguished for the effect of his light. Bartol. Schidone is one of the best colourists of this school. The Bibienas, the Molas, Al. Tierini, Pietro di Cortona, Ciro Ferri also deserve mention. At the head of the naturalists, who, with a bold and often rash pencil, imitated nature, without selection, stands Michael Angelo Merigi, or Amerigi da Caravaggio (born 1569). His chief opponent in Rome was D'Arpino, who stood at the head of the idealists, or rather of the mannerists. Caravaggio and his successors, Manfredi, Leonello Spada, Guercino da Cento, &c., often took common nature for a model, which they servilely imitated, thus profaning the genuine dignity of the art, though they cannot be denied strength and genius. About this time, the beginning of the seventeenth century, the *bambocciate* were introduced. (See *Peter Laar*.) Many artists, especially Michael Ang. Cerquozzi, surnamed *delle battaglie*, and *delle bambocciate*, followed this degenerate taste. Andrea Sacchi made great efforts to oppose him. His drawing was correct and grand; Raphael was his model. His most famous scholar was Carlo Maratto (born 1625, at Camerano), whose style was noble and tasteful. The cavaliere Pietro Liberi, Andrea Celesti, the female portrait painter Rosalba Carriera (born at Venice, 1675, died 1757), who was distinguished for her drawings in pastel, the graceful Francesco Trevisani, Pinzetta Tiepolo, and Canaletto, a painter in perspective, were the celebrated Venetian painters of this time. Carlo Cignani (born 1628, died at Bologna, 1719) acquired a great reputation by his originality and the strength and agreeableness of his colouring. Of his scholars, Marc. Antonio Franceschini was distinguished (born 1648, died 1720), whose works are charming and full of soul. Giuseppe Crespi, called *Spagnuolo*, deserves mention for his industry and correct style, but his pictures have unfortunately become very much

defaced by time. Among the Romans, Pompeo Battoni (born 1708, died 1787) was principally distinguished, and was a rival of the celebrated Mengs. Angelica Kaufmann deserves to be mentioned.—We must not forget the Neapolitan and the Genoese schools. Of the Neapolitans, we name Tommaso de' Stefani (born 1280), Fil. Tesauro, Simone, Colantonio de' Fiori (born 1352), Solario il Zingaro, Sabatino (born 1480), Belisario, Caracciolo, Giuseppe Ribera Spagnoletto (born 1593), Spadaro, Francesco di Maria (born 1623), Andrea Vaccaro, the spirited landscape-painter Salvator Rosa (born 1615), Preti, called *il Calabrese* (born 1613), and Luca Giordano (born 1632, died 1705), who was called, from the rapidity of his execution, *Luca fa Presto*. Solimena (born 1657) and Conca belong to the modern masters of this school. The Genoese can name among their artists Semino (born 1485), Luca Cambiasi (born 1527), Paggi Stromi, called *il Prete Genovese*, Castiglione (born 1616), Biscaino, Gaulli, and Parodi. Perhaps the most distinguished of the living painters of Italy is Camocchini. This reputation, however, is not allowed him without dispute by foreign countries, and even by many artists of his native land. His style is grand, and purely historical; his drawings are even more highly esteemed than his paintings. His pieces, however, are cold, and their estimation seems to have diminished. Landi is a distinguished portrait painter, though his colouring is rather cold. The pencil of Grassi possesses an inimitable grace, and a true enchantment. Benvenuti, director of the academy in Florence, is the first artist there. A French artist (Fabre) in Florence is the competitor of Benvenuti; his landscapes and his pastoral scenes are equally excellent. Colignon is also a very able artist, in the same place. Appiani, who died a few years ago at Milan, was particularly celebrated for the grace of his female figures; and Bossi had equal reputation, in a more serious and severe style. The Florentine Sabatelli's sketches with the pen are highly esteemed. Ermini, in Florence, is a charming miniature painter, in Isabey's manner. Alvarez, a Spaniard, and Ayes, a young Venetian, are in high repute at Rome. The young artist Agricola is particularly distinguished among the artists of Rome. He is a native of Urbino. In purity of style, he is thought to surpass all modern artists. (For the history of Italian painters, see Lanzi's *Storia Pittorica*.)—In the art of engraving, the Italians have acquired great eminence. Tommaso Finiguerra, who flourished 1460, was the first celebrated master of this art, which he taught to Baccio Bandini. They were succeeded by Mantegna; but Marco Antonio Raimondi, of Bologna, who lived in 1500, was the first to introduce greater freedom into his engravings. His copies of Raphael have always been highly valued, on account of their correctness. His manner was imitated by Bonasone, Marco di Ravenna, Di Ghisi, and others. Agostino Carracci, Parmeggiano, Carlo Maratti and Pietro Testa etched some excellent works. Stefano della Bella was distinguished for his small, spirited, and elegant pieces. Among the moderns, Bartolozzi deserves mention in stippled engraving. Cunego, Volpato, and Bettelini are also distinguished; but, above all, the Florentine Raphael Morghen, who has carried the art of engraving to a degree of perfection never before anticipated. The labours of Morghen, and yet more those of Longhi, perhaps the most admirable of all modern engravers, of Toschi, of Anderloni, of Folo, of Palmerini, of Lasinio, of Garavaglia, Lapi, Schiavonetti, evince an activity, to which new employment and new excitement have been afforded by the eagerness of travellers, and the number of splendid works on buildings (such as those on the cathedral of Milan,

the Carthusian monastery of Pavia, the sacristy of Sienna, the Campo Santo of Pisa, the *Mausolei sepolcrali* of Tuscany, the principal edifices of Venice, the *Chiese principali di Europa*). One of the latest and best is the work of the brothers, Durelli, *La Certosa di Pavia*. The painter Francesco Pirosano, whose description of Milan exceeds all others in exactness, has also given us a description of the celebrated Carthusian monastery. As a medium between painting and sculpture (see *Sculpture*), we must mention mosaic, in which many paintings have been imitated in Italy, from the wish to render the master works imperishable. There is a distinction made between the Roman mosaic executed by Tad. Giotto, and Cavallini, and the Florentine. (See *Mosaic*.) Mosaic painting seems to have flourished as well in France, whither it was transplanted, as in Rome. The art of working in *scagliola* (see *Scagliola*) has flourished for two centuries in Tuscany. In later times, Lamberto Gori has distinguished himself in this branch. Rome is still the metropolis of the arts. Pope Pius VII. generously supported the plans of that lover of the arts, cardinal Gonsalvi; and the Chiaramonti museum, by every account the most superb part of the long galleries of the Vatican, will be a lasting monument of his noble patronage. All friends of the sublime and beautiful deeply felt the accident that befell St Paul's church, near Rome, in the conflagration of 1823. To restore it would hardly be possible. The loss of this noble Basilica is not adequately compensated by the church of St Peter and Paul, built opposite the castle of Naples, nor by the temple of Posagno, which, before it was finished, received the ashes of its founder, the great Canova. As a monument, to the embellishment of which that distinguished man contributed the last efforts of his genius, this church is a legacy highly to be esteemed by Italian artists. Sculpture and painting here again meet architecture in a sisterly embrace. Canova's death was the cause of its first solemn consecration. (For a particular account of Canova, see the article.) Notwithstanding the excellence of their master, little is to be expected from the Italians of Canova's school. The monuments which were executed or planned by Ricci for the present grand-duke of Tuscany at Arezzo, by Fieschi for the princesses of the house of Este at Reggio, and by Antonio Bosa to the memory of Wackerhausen, rather depress our hopes than exalt them. The principal ground of hope of future excellence is in the love which has been generally awakened for the plastic arts. Gem engraving has been carried to a very high degree of perfection; and Berini's labours well merit the wide reputation which they have acquired. As medalists, Manfredini in Milan, Paltman and Mercandelli have produced works with which other countries present little that can compare. In Rome, Girometti and Cerbara are highly esteemed in this branch of art.

*Italian Music.* The style of music now prevalent in Italy is characterised by the predominance of melody and song to the neglect of harmony, and is distinguished from the old Italian music. Like other branches of modern art, the music of modern times sprang from religion. The history of the art, after pointing out a few imperfect glimmerings of ancient music, conducts us to Italy, where, in the course of centuries, the ancient was first lost in the modern. Here we first find the proper choral song, the foundation of modern church music, which was at first sung in unison, chiefly in melodies derived from the old Greco-Roman music, and adapted to Christian hymns and psalms. (See *Music*, and *Music, Sacred*.) It seems to have had its origin when bishop Ambrose, in the fourth century, introduced into the western

church songs and hymns adapted to the four authentic modes of the Greeks, and appointed psalmists or precentors. Gregory the Great, in the sixth century enlarged the choral song by the plagal modes. From this time singing-schools were multiplied, and much was written upon music. The most important inventions for the improvement of music generally, we owe to the eleventh century, and particularly to the Benedictine Guido of Arezzo, who, if he did not invent the mode of writing musical notes and the use of the clef, improved and enlarged them, determined the exact relations of the tones, named the six tones of the scale (see *Solfeggio*), and divided the scale into hexachords. In the thirteenth century, the invention of music in measure was spread in Italy, dependent upon which was that of counterpoint and figured music. Instruments were multiplied and improved in the fourteenth and fifteenth centuries. Many popes favoured music, particularly vocal, and consecrated it by their briefs; yet the ecclesiastical ordinances restrained the independent development of music. Much instruction was given in singing in the fifteenth century, and not entirely by monks. Music acquired the rank of a science, and vocal music in counterpoint was developed. In the sixteenth century, we discover distinguished composers and musicians—Palestrina, composer for the chapel of pope Clement XI., whose works possess great dignity and scientific modulation, and his successor, Felice Anerio. Nannino da Vallerano, who, together with Giovanni da Balletri, were considered as distinguished musicians; also the celebrated contrapuntist and singer, Gregorio Allegri, and the great writer upon harmony, Giuseppe Zarlino, chapel-master at Venice. Music at Rome and Venice was cultivated with the greatest zeal. Hence it went to Naples and Genoa; and all Italy, Schubert says, was soon a loud-sounding concert-hall, to which all Europe resorted to hear genuine music, particularly beautiful singing. In the seventeenth century, we meet with the first profane music. The first opera was performed at Venice 1624, at first with unaccompanied recitatives and choruses in unison; it spread so quickly, that the composers of spectacles were soon unable to supply the demands of the people, and from forty to fifty new operas appeared yearly in Italy. This caused great competition among the Italian musicians. Thus the peculiar character of the Italian music, not to be changed by foreign influence, was developed the more quickly, because this species was cultivated independently, and unrestrained by the church. Already, in the middle of the seventeenth century, when the music of the theatre was continually advancing, simplicity began to give place to pomp and luxuriance, and the church style to decline. Music (says Schubert) united the profane air of the drama with the fervour of the church style, and this was the first cause of the decline of the latter. Let us now consider the principal periods of the former. Vocal music must have been first; it was regulated by the discovery and improvement of instruments; thence arose the simple, grand church music of the fifteenth and sixteenth centuries; with it various forms of national song were developed. On the stage, the higher style of music flourished independently. Here the Italian, without much attention to the poetical part of the performance, which was, indeed, only the hasty work of a moment, followed his inclination for melody and sweet sounds, which appears even in his language. All the southern nations show a great sensitiveness, and melody is to them as necessary as harmony to the inhabitants of the north; but to no nation so much as to the Italians, whose beautiful climate and happy organization for song (Italy produces the most beautiful alto

and tenor voices—few bass) made melody their chief aim in their music. On the other hand, the simplicity of melody degenerated into effeminacy and luxuriance, from the time when vocal music developed itself independently, and the voice, but little supported by the instrumental music, began to be cultivated like an instrument; when, instead of poetical expression and truth, mere gratification of the ears, not deep emotion, but a momentary excitement, and a rapid change of tones, with the avoidance of all dissonance, were principally desired; when music began to predominate over poetry, which first took place on the stage, and thus the musical part of the performance obstructed the improvement of the dramatic and poetic. This taste spread over other countries so much the more easily, as Italian music had advanced, by rapid strides, far before that of the rest of Europe, as appears even from the predominance of Italian terms in musical language. This artificial development of the song was promoted by the introduction of soprano singers on the stage, which destroyed the possibility of poetic truth in dramatic representation. The voice was cultivated to the highest degree by means of the numerous conservatorios and singing schools. To this was added the great encouragement and the extravagant rewards of distinguished singers (Farinelli purchased a duchy); the great opportunities afforded for singing (as every place of consequence in Italy had its theatre, and many had several); besides which, music is an essential part of the service of the Catholic church, and castration was permitted *ad honorem Dei*, as a papal brief expresses it. The excessive culture of the voice must necessarily lead to the treatment of it as an instrument, to the neglect of poetical expression. Instrumental music, too, in this case, necessarily becomes subordinate. Instrumental music should not indeed overpower the song, as is the case in much of the French and German music; but in the Italian music, the composer is almost restricted to showing off the singer, and cannot develop the fullness and depth of harmony which depends upon the mingling of consonance and dissonance. This is the reason why the masterpieces of Mozart have never entirely satisfied the Italians. Among the best composers, since the seventeenth century, are Girolamo Frescobaldi, Francesco Foggia, Bapt. Lully, the celebrated violinist and composer Arcangelo Corelli. To the singers, of whom the most were also composers, belong Antimo Liberati, Matteo Simonelli, both singers in the chapel of the pope. In the beginning of the eighteenth century, Ant. Caldara was distinguished. He increased the effect of the singing by the addition of instruments, but his style partook much of the theatrical. There were, besides, Brescianello, Toniri, and Marotti. In the middle of this century, Italian music, especially theatrical, flourished, particularly at Naples, Lisbon, and also in Berlin. This has been declared by some the most brilliant period of Italian music. There are some distinguished instrumentalists in Italy, as the organist Scarlatti and Martinielli, the violinist Tartini (who, even in the theory of his instrument, was distinguished, and established a school, which was devoted particularly to the church style), Domenico Ferrari, Geminiani, Ant. Lolli and Nardini, scholars of Tartini, also the player upon the harpsichord and composer, Clementi, in London, and Paganini. Among the composers of the eighteenth century, are mentioned Traetta, who, through his refinements, injured the simplicity of composition; Galuppi, distinguished by simple and pleasing song, rich invention, and good harmony; Jonelli (q. v.), who gave greater importance to instrumental music; Maio; Nic. Porpora, the founder of a new style of singing, distinguished

for his *solfeggios* in church music; Leo; Pergolesi, whose music is always delightful, from its simple beauty (e. g. his *Stabat Mater*); Pater Martini, at Bologna; the sweet Piccini, rival of Gluck; Anfossi; the agreeable Sacchini (*Edip.*); Sarti. Of a later date are Paesello, Cimarosa, the ornament of the *opera buffa*, and Zingarelli (*Romeo and Juliet*), Nasolini, Paganini, Niccolini, Pavesi, and the now much celebrated Generali and the copious Rossini. More like the Germans were Salieri, and the thorough Righini (he likewise has written *solfeggios*). Cherubini and Spontini have more of the French character. Among the celebrated male and female singers of Italy, since the eighteenth century, are Francesca Cuzzoni Sandoni, and her rival Faustina Bordoni (afterwards the wife of Hasse), and the Allegrandi, the sopranists Farinelli, Caffarelli, Genesino, Caristini, Marchesi: in later times, the celebrated Crescentini and Veluti; also the singers Baldassore Ferri, Siface Matteucci; the tenorists Millico, Pacchierotti, Bixi Benelli; the female singers Tesi, Mingotti, Gabrielli, Todt, Vandi, Marchetti, the sisters Sessi, particularly Imperatrice and Mariana Sessi, Angelica Catalani, Camporesi, Borgondio. The Italian school is yet unequalled in whatever depends upon the mere improvement of the voice; but the slavish imitation of their manner leads to affectation; therefore the German singers employ it no further than they can without losing the spirit and poetical expression which the German song aims at.

*Travels in Italy.* No part of Europe has been so much visited as Italy, and none deserves to be visited more than this charming country, where a cloudless sky sheds perpetual brilliancy on the monuments of ancient greatness, and the relics of ancient art, which conspire with the finest works of modern genius, to delight the eye, and to carry back the mind to the great men and great events of former times. The sight of modern Italy led Gibbon to write the sad story of the decline of her ancient grandeur; and how many poets have owed to Italy their inspiration! It is impossible to see Italy, and not feel the grave monitions of history, or to pass through her happy vineyards without being cheered by the scene, or to gaze on her works of genius without feeling the worth and the dignity of the fine arts. No wonder, then, that Italy is visited from all quarters. During the general peace in Europe, from 1815 until 1830, crowds of foreigners, particularly Englishmen, hastened to the beautiful peninsula. The latter were so numerous, that the lower classes of Italy called every foreigner an *Inglese*. Among these there were, of course, great numbers who, without capacity for enjoying what they saw, hurried through the country according to the direction of their guide-books, in order to be able to say, at the tea-tables in London, How beautiful the view from Monte Pincio is! Every one who has been in Rome must have met with such a traveller, his *l'asari* in his hand, working his way with servile conscientiousness, through the beauties of the place. Expedition being an object with many of them, the shortest process for seeing all that was to be seen was soon found out, and flocks of travellers, at particular seasons, migrated to particular places. The average period of a jaunt through Italy is six months. The end of the journey is usually Naples, from which travellers advance south as far as the ruins of Paestum. The Alps must be passed early in the autumn. The fairy islands of the Lago Maggiore, at that time, still wear their delightful drapery of fruits and leaves. The traveller then enters, at once, the south of Europe, so different from the north. For visiting the principal places in Upper Italy, the Bolognese, and Tuscany, there are two months before the beginning of the

carnival, which, of course, must be enjoyed in Rome. After having visited the galleries and monuments at and about Rome, the traveller proceeds, during Lent, to Naples, to see the spring awaken in the Campagna. At Easter, he returns to Rome. He could visit Italy without hearing the heavenly music in the Capella Sistina, during Passion week! There will perhaps be time, on the return, to make an excursion to the Mark of Ancona; if not, no one who has been to Rome through Sienna, will now but take the road through Terni, Perugia, and Arezzo. Genoa and Venice, as the most western and eastern points, are convenient to begin or close the journey with. It may be better, however, to begin with Lombardy and Genoa, in the autumn, and not to extend the period of return far into the hot season. Lombardy attracts but little, after Rome, Florence, and Naples, have been visited; but Venice, this melancholy Venice, still remains an object of interest, even in her decrepitude under the Austrian yoke. Such a journey will occupy from the beginning of October until the middle of May, and will enable the traveller to see the finest parts of the country and the most remarkable works of art. But to become thoroughly acquainted with Italy, as it is and as it was, no one can stay long enough. Rome alone will fully occupy a man's life. He who wishes to become particularly acquainted with the middle ages, and to form a lively picture of them, will remain longer at Florence and Pisa. Late in a moonshiny night, when every thing is quiet, walk through the streets of Florence, and you may easily imagine yourself contemporary with the Medici. He who wishes to devote himself to the antique or to Roman history will stay longer in the *alma città*. Here he will also find himself at the fountain head of ecclesiastical music. He who desires to enjoy the beauties of a bountiful nature, will remain longer in Naples, here like a paradise surrounded by the fields of Campagna, where the gigantic vine twines round the rocky pillars, and forms an embowering shade over the radiant grain. He who prefers to see a country where nature and man have not been much influenced by civilization, will proceed to Calabria and Sicily, which afford also the richest harvest to the human and mineralogist. He who wishes to become more fully acquainted with the history of the fine arts of the middle ages, will go to the smaller places, distant from the great roads, where he will find innumerable treasures, often unknown to most Italians themselves, as the historian finds rich treasures in the manuscripts stored up in the monasteries, illustrative of the contests of Italian powers among themselves in the middle ages, as well as of the great contest between the secular and ecclesiastical powers, the emperor and the pope: and what a boundless field is opened before the scholar in the Vatican! There are no ways of travelling in Italy, with post-horses, in which case a carriage belonging to the traveller is almost indispensable, or with the *retturno* (or hired coach). He who travels without a family and wishes to become acquainted with the people will do best to adopt the latter mode. The traveller makes his bargain with the *retturno*, not only for conveyance, but also for supper and lodging. The general price for the conveyance, from thirty to forty miles a day, together with the meal and lodging, is about a ducat per day. As the reputation of a *retturno* depends upon the good treatment of the travellers, it is his interest to procure a good horse and a clean bed; thus travellers are spared the trouble of bargaining with the host. That the ushers in Italy have a general disposition to swindle the traveller, is certain; and this leads many travellers, particularly English, not to touch a trifle in the

men without making a bargain; for which very reason they are regularly overreached. The same disposition makes many English travellers so troublesome in Germany, where, the living being cheap, they expect to pay next to nothing in the first hotels, so that some hotels have actually refused to admit them. In large cities, where the traveller expects to stay some time, his best rule will be to make a fair bargain after the first day, when he knows what he has to expect. Another great inconvenience for travellers arises from the *ciceroni* or *servitori di piazza*. These people, who have a share of what the *custodi* and the poorer possessors of some single curiosities receive from the travellers, have an interest in directing the traveller to every corner where an inscription, a piece of a column, &c., is to be found. But how avoid this, since a *cicerone* is indispensable? Two general rules may be found serviceable; not to attend, in Italy, to any thing but what is peculiar to Italy; collections of minerals, Japan porcelain, &c., are to be found in other countries; and, secondly, to prepare one's self for the journey, and to know beforehand, in general, what is to be seen. Of course, these rules are only for those who do not stay for a long time in a place, and have no time to make acquaintances for themselves. Three nations, particularly, have furnished descriptions of Italy, the British, Germans, and French. We recollect to have seen a very old and curious little book, a Guide through Italy for Pilgrims. The images of the virgin, miraculous relics, &c., of course formed the great mass of the book; but antiques, columns, &c. had received a Christian character, and were named after the apostles, &c. The works of which we here speak, properly begin toward the end of the seventeenth century, at which time the descriptions of Italy assume a more independent character. Since that time, the number has, particularly of late, greatly increased, so that this branch of literature, in Germany, is almost in dispute. Among the earlier works in English, the most esteemed are those of Burnet, Addison, and the others mentioned below. Gilbert Burnet, bishop of Salisbury, travelled, in voluntary exile, through France, Germany, Switzerland and Italy, in 1685. His observations relate principally to religion and politics, on which subjects his views are those of a zealous Protestant and Whig. His work was succeeded by that of Adkisson—Remarks on several Parts of Italy (1705), chiefly devoted to antiquity—and the less known works of John Breval (1726) and Edward Wright (1727). The journal of the French emigrant Blainville, who had become naturalized in England, appeared after his death, and was edited by Turnbull and Guthrie in 1742. The remarks of these travellers are chiefly directed to the classical antiquities of Italy, and they therefore have been designated by the name of *classical travellers*. Smollett's travels treat chiefly of modern Italy and the inhabitants, and are full of a morbid querulousness. The same is true of Sharp's. Barretti defended his country from the attacks of Smollett and Sharp, in his Account of the Manners and Customs of Italy (1767). John Moore's View of Society and Manners in Italy is still interesting, and is rich in characteristic anecdotes. Patrick Brydone's picturesque description of Sicily is too celebrated to be passed over in silence, though it relates merely to that island. Among the numerous recent publications on Italy, few have acquired reputation in foreign countries. We may mention Forryth's Remarks on Antiquities, Arts and Manners during an Excursion in Italy in 1802—3 (London, 1813). Eustace's Classical Tour through Italy (1802, in two vols., much enlarged in 1817, in four vols.), is prejudiced and inaccurate. Lady Morgan's Italy betrays the novelist. It is not to be recom-

mended as a guide through Italy. The Florentine A. Vieusseux, who left his country in early youth, and entered the British service, travelled through Italy, and wrote Italy and the Italians in the nineteenth Century (London, 1824, two vols.). Among the other English books of travels in Italy, which have appeared within late years, may be mentioned Bell's Observations on Italy. Simon's valuable Tour in Italy and Sicily appeared in 1828; Narrative of three Years' Residence in Italy appeared in London, 1828; Lyman's Political State of Italy, Boston, 1820; Rembrandt Peale's Notes on Italy, Philadelphia, 1831; Bigelow's Tour in Sicily and Malta, Boston, 1831. Of the French works on this subject, we may cite first the work of Maximilian Misson, a counsellor of parliament (in 1691), much read at the time in England and Germany. The works of Rogissart (1706), of Grosley (*Mémoires sur l'Italie par deux Gentilshommes Suédois*, 1764), and of madame du Bocage (1765), did not preserve their reputation long. The abbé Richard's *Description de l'Italie*, &c. (1766, six vols.) was useful, as was also the work of Lalande (most complete edition, 1767), written on the same plan. It is a systematic description of a tour, and is the basis of the German work of Volkmann. Dupaty's popular *Lettres sur l'Italie* (1788) are recommended by elegance of style and warm feeling. Their matter is not important, and affords little information to the traveller. The Corinna of madame de Stael does not belong to this branch of literature in form, but it does in substance. It is a noble production throughout, and even where the views are erroneous, they are nevertheless instructive. The *Lettres sur l'Italie, par A. L. Castellan* (Paris, 1819, three vols.), are entertaining and instructive. Germany, which is fertile in every branch of literature, is so in descriptions of Italy, or travels in Italy. There are some excellent works in German, treating of the scientific treasures of Italy; but this is not the place to enumerate them. The German descriptions of Italy are often characterized either by a minute collection of facts, without much attention to agreeable arrangement, or a romantic exaggeration, which arrays all Italy in heavenly colours, and inhales fragrance from the very *immondezza*. The learned Keyssler, who wrote in 1740, complains of a host of predecessors. His work (which was augmented in 1751 and 1776) was followed by a number of translations and *rifacimenti* of English and French works, particularly the excellent account of Volkmann, already mentioned (in 1770 and 1771, with additions by Bernouilli since 1777, six vols.). A new continuation and correction of this work would afford a very useful manual for travellers. Archenholz's *Italien* (1785, augmented in 1787) represents the country according to English views. Jagemann opposed him in a vindication of Italy (*Deutsches Museum*, 1786). To this class of works belong Goethe's Fragments on Italy, published at the end of the last century, and his Journal, published but a few years since. Count Leopold von Stolberg (1794) wrote a description of his journey. Frederica Brun, Kuttner, (1796 and 1801), E. M. Arndt, Seume (his *Spaziergang nach Syrakus* is a work fitted to gratify a sound mind, and appears to advantage among the host of sentimental publications, though it is by no means a guide), Gerning, Benkowitz, and J. H. Eichholz, are among the legion of writers on Italy. Kotzebue poured his satirical spirit, also, on this country. P. S. Rehfues has, since 1807, published several works on Italy. Madame von der Recke's Journal was translated into French by Mad. de Montolieu, and is a compendious travelling library, which touches on almost every thing important to a traveller. Kephallides (1818) unites much information with

animated description. F. H. von der Hagen's work (1818—1821, four vols.) is valuable, particularly for its observations on the arts in the middle ages, as attention is generally paid only to classical art, and to the modern since the time of Raphael. Muller's *Rom, Römer, und Römerinnen*, has met with applause as a picture of manners and customs. There exist a number of descriptions of parts of Italy, which we have not room to enumerate. On Sicily, one of the latest works is *l'oyage en Sicile fait en 1820 et 1821, par Auguste de Sayve* (Paris, 1825, three vols.). Neigelaur's *Handbuch fur Reisende in Italien* (Leipsic, 1826) contains much information of value to travellers. Among the works which portray the beauties of Italy, one of the best is *l'ues pittoresques de l'Italie*, by Coignet, lithographed (Paris, 1825).

ITE, MISSA EST (*Latin*, go—the meeting is dissolved); a formula by which, on joyful feasts, the end of the low mass is announced to the people, and the assembly dismissed. The priest steps into the centre of the altar, and sings these words after the *Dominus vobiscum*. After a mass for the dead, instead of these words, he sings, *Requiescat in pace*, on which the response is, *Amen*. In Lent, Advent, and the days of penitence, he says, *Benedicamus Domino*, to which the response is *Deo gratias*. The word *mass* is derived from *missa est*.

ITHACA (*Uaan*), or, as it is called by the moderns, *Thiaki*; one of the seven Ionian islands lying in the gulf of Patras; lon. 21° 1' E., lat. 38° 36' N.; eighteen miles long, and not above five broad; population, 8000. The whole island is rugged and uneven. Ithaca is celebrated as the island of Ulysses, and is minutely described by Homer in the *Odyssey*. Of the places mentioned by Homer, many can be traced with great appearance of probability. The *Kepassos oripa* (Od. xiii. 403) is still called *Coraro petra*. The ruins of Cyclopean walls are described as similar to those of Argos, Tiryns, and Mycenæ. The spring of Ithacus and the walls of the city, as well as the Acropolis, can also be traced. A sculptured rock, called *Homer's school*, somewhat resembles that which bears the same name in Scio (Chios). Pataras, vases, bracelets, chains, strigils, mirrors, lamps, coins, &c., have been dug up in an ancient burying-ground here.

ITHACA, the name of an American town, in the

state of New York, situated about a mile and a half south of the head of the Cayuga lake, being 17 miles west of Albany; population about 4500.

ITURBIDE, AUGUSTIN, was born at Valladolid de Mechoacan, in New Spain, in 1784. Being of a family of some consideration in his country, he received a very careful education. Until 1810, he held no higher rank than that of a lieutenant in the provincial regiment of his native city. At this period, when the troubles in Mexico broke out, he entered into active service against the patriots, and was engaged in various contests with bodies of his insurgent countrymen. Borne along by circumstances in the career of arms, he had risen, in 1810, by his valour and capacity, to the command of what was called the *northern army*, which occupied the provinces of Guanajuato and Valladolid. About this time, he was suspected and accused of want of fidelity to their cause, by some of the royalists, but was acquitted of the imputation by the viceroys Calleja and Apodaca. But the disgust which he felt a consequence of this charge, led him to retire for a while from active service. In 1820, we find Iturbide again in the field, under circumstances which gave him unexpected importance. At that period, the imprudent acts of the Spanish cortes produced so much exasperation among the clergy and the partisans of absolutism in Mexico, that these persons united to effect the independence of their country. They selected Iturbide as their agent, knowing his zealous agency in putting down the revolutionists and republicans of past years, and wholly unconscious of the views of personal aggrandizement which he entertained. Being furnished with some money by them, he set out for the south; and, having seized a convoy of specie on his route, he soon formed a junction with Guerrero, one of the patriot chiefs. Meanwhile emissaries had been despatched in all directions to prepare the people, who were accordingly ripe for revolution. At length the army reached Iguala, where (February 24, 1821) Iturbide proposed the plan which bears the name of that place;—the great objects of this instrument being the independence of Mexico, the protection of religion, and the union of the Spaniards and Mexicans. At the same time, an offer of the crown was made to Ferdinand VII., or to any other member of the royal family of Spain. On the strength of this plan, Iturbide continued his march to Queretaro, and was soon joined by Guadalupe Victoria, the most devoted of the friends of liberty. Meantime the viceroy O'Donouja arrived from Europe, and, finding the whole country virtually with Iturbide, signed a treaty at Cordova (August 27, 1821), according to the provisions of the plan of Iguala. The road to power was now entirely open before Iturbide. He took possession of the capital in the name of the nation, and established a regency, consisting of members nominated by himself, and wholly under his control. The republican party soon was the object of his movements. A congress had been assembled, which made various attempts to counteract his designs by diminishing his power, and at last brought the matter to an open rupture and a crisis. Iturbide, seeing no other way to preserve his authority, resolved to usurp the crown, through the subserviency of his troops. Accordingly, May 18, 1822, the garrison and a part of the populace of Mexico rose and proclaimed Iturbide emperor, under the name of Augustin I. The next morning, congress was convened in extraordinary session, in the midst of the acclamations of the multitude, whose cries often drowned the voices of the deputies. The agents of Iturbide obtained a decree requiring his presence; and he appeared, accompanied by a number of military officers, having been drawn through

the streets by the rabble. His election to the imperial dignity was proposed and discussed in his presence, and was voted for by seventy-seven deputies, out of ninety-four who had assembled, being about one half the whole body of delegates. He returned to the palace as he came, in a coach drawn by the people. Shortly afterwards, the congress decided that the crown should be hereditary in the family of Iturbide, gave to his sons and his father the title of *princes*, fixed upon him a yearly allowance of a million and a half of dollars, and established an order of knighthood, called the *order of Guadalupe*, thus completing, in every thing, the accessories of the new monarchy. All these arrangements were voted with a degree of unanimity, which clearly proved the absence of liberty; and the provinces yielded a blind submission to what was decreed in the capital. The friends of liberal institutions, overawed and held at bay by the power of the usurper, fled to their wonted retreats, or temporised until a fitting season should arrive for acting with union and efficiency. But they could not, and did not, acquiesce in a state of things so adverse to their feelings. Iturbide was driven by his necessities to hasten affairs to a crisis. In October, 1822, he seized and confiscated, without legal process, a convoy of 1,200,000 dollars, on the way from Mexico to Havana. Also in the month of August preceding, he had caused several of the members of congress to be arrested, regardless of their privilege of personal inviolability. Finally (October 30, 1822), he ordered the dissolution of congress, causing the hall to be shut, of his own authority, and, on the same day, organised a junta to take the place of the legislative body, and nominated all the members himself. To supply the exigencies of the government, recourse was then had to forced loans, which served the more to exasperate the minds of the people, already disgusted with the successive usurpations of Iturbide. Circumstances, however, foreign to his acts of general oppression, brought on the catastrophe. At this time, the Spaniards retained possession of the castle of San Juan de Ulua, which commanded the port of Vera Cruz. The emperor had left the city of Mexico, and advanced as far as Jalapa, intending, if possible, to obtain an interview with the governor of the castle. Disputes had previously arisen between general Santa Anna, governor of Vera Cruz, and general Echavarrri, who commanded the southern division of the Mexican army; and Santa Anna was summoned to Jalapa by the emperor, to answer to the charges of Echavarrri. Santa Anna counted much upon the services which he had rendered Iturbide, and on his own popularity; but, to his great surprise, he was treated harshly, and dismissed from his command at Vera Cruz. Hastening back to the garrison, before the news of his disgrace could reach them, he excited them to revolt, for the purpose of dethroning Iturbide, and establishing a republican government. He found the troops ripe for his purpose, and lost no time in advancing to Puente del Rey, where several skirmishes took place between the republicans and the imperialists under Echavarrri. At length Victoria made his appearance, and was appointed commander-in-chief of the insurgents; and, in February, 1823, Echavarrri and his army joined forces with Victoria and Santa Anna, by the convention of Casa Mata. Defection now became general among the officers of the army, and in all the provinces, so that Iturbide saw plainly that his cause was hopeless, and hastily assembled at Mexico the dispersed members of congress, and tendered to them his abdication of the crown. This happened March 20, 1823. Congress very generously agreed to grant Iturbide a yearly pension of 25,000 dollars on condition of his leaving

the Mexican territory for ever, and residing somewhere in Italy, making suitable provision for his family in case of his death. He proceeded to the coast, under escort of general Bravo, and embarked May 11, 1823, for Leghorn. He might have continued to live happily in one of the charming villas of Tuscany, had he not been impelled by an insane ambition to attempt the recovery of his lost empire. With this object, he left Italy for England, and embarked for Mexico, May 11, 1824, precisely a year after his departure from it, and arrived in sight of the port of Soto la Marina, July 14. During the year that had elapsed, the Mexicans had adopted a republican constitution, and Iturbide had no party nor friends in the nation. The government had been apprised of his leaving Italy, and suspected his design. A decree was passed, bearing date April 28, 1824, declaring him to be proscribed as a traitor, and requiring that, in case he landed in the country, the mere fact should render him a public enemy. Wholly deceived in regard to the fate which awaited him, Iturbide landed at Soto la Marina, accompanied only by his secretary, a Pole, named Beneski, and was almost immediately arrested by order of D. Felipe de la Garza, the commandant-general of the state of Tamaulipas, in which Soto la Marina is situated. La Garza lost no time in conducting his prisoner to Padilla, the provincial capital, and demanding instruction how to act, of the provincial legislature. He was instructed to put in execution, forthwith, the decree of congress, of April 28, by causing Iturbide to be shot,—apprehensions being entertained lest any delay in the enforcement of the decree should be the cause of some troublesome, although of necessity abortive, movement, on the part of the people. This took place July 18th; and, on the 19th, La Garza notified Iturbide to prepare for death on the same day. Iturbide in vain solicited for a reprieve until the general government could be informed of his situation, and have opportunity to decide upon his case. This, of course, La Garza denied him; and at six o'clock in the afternoon, after having confessed himself, he was conducted to the place of execution, where sixty or seventy soldiers stood in their ranks, under command of La Garza. Iturbide then made a short address to the assembled people, protesting his innocence of any treasonable purpose, exhorting them to observe the duties of patriotism, religion, and civil subordination, and declaring that he pardoned his enemies. He was shot dead at the first fire; and his body was interred as decently as the means of the small town permitted. While this was passing at Padilla, the wife of Iturbide and two of his children, who had accompanied him from England, had landed at Soto la Marina. They brought with them a large quantity of proclamations, circulars, and other papers, intended to aid the design of the ex-emperor, together with his imperial mantle and other insignia. So soon as the captain of the brig in which they came learnt the fate of Iturbide, he cut his cables, and stood out to sea, leaving the widow and children of Iturbide totally destitute of every necessary, and at the mercy of the very men who had just ordered the execution of her husband. But the feelings of the Mexican government were just and liberal. They continued to the widow the pension promised the family of Iturbide at the time of his abdication, annexing only the condition that she should live either in Columbia or the United States, in which latter country she has ever since resided. Such was the end of a man, estimable in his private character, and not without talents, who, if his fortune had led him to use his influence in the establishment of a free government, might have con-

tinued long at the head of affairs, and finally have departed from life respected and honoured as a patriot, instead of prematurely suffering the ignominious death of a malefactor. *Pamphleteer*, No. 56; *Annales Biographiques pour 1826*; Poinsett's *Mexico*.

ITUZAINGO; the scene of a celebrated victory gained by the troops of Buenos Ayres, under Alvear, over the Brazilians. In the campaign of 1827, the republicans pushed their forces into the province of Rio Grande, and encountered the enemy on the field of Ituzaingo, February 20, 1827. The battle was obstinately disputed for six hours, but was gained at length by the reiterated and furious charges of the cavalry of the Banda Oriental. The Brazilians lost marshal Abreu, ten pieces of artillery, all their munitions of war, and baggage, and about 2000 men.

ITYS, son of Tereus and Procne. See *Philomela*.

IVICA, IVIZA, or IBIZA (*Ebura*); an island of the Mediterranean, belonging to Spain, and the principal of the group called the *Pityusæ*. Its extent is 190 square miles; its population, 21,094. The soil is fertile, producing corn, wine, oil, fruit, flax, and hemp, with little labour. About 15,000 tons of salt are annually obtained by evaporation; and it forms, with fish and wood, the chief article of export. Fifty-two miles from Majorca. The capital is of the same name, and has a good harbour. Population, 2700.

IVORY; the substance of the tusk of the elephant. Ivory is esteemed for its beautiful cream colour, the fineness of its grain, and the high polish it is capable of receiving. That of India is apt to lose its colour, and turn yellow; but the ivory of Achem and Ceylon is not chargeable with this defect. Ivory is used as a material for toys, and as panels for miniature-paintings. To prepare it for the latter purpose, it is to be washed with the juice of garlic, or some other absorbent composition, to remove its oily particles. The shavings of ivory may be reduced into a jelly, of a nature similar to that of hartshorn; or by burning in a crucible, they may be converted into a black powder, which is used in painting, under the name of *ivory black*. Ivory may be stained or dyed: a black colour is given it by a solution of brass and a decoction of logwood; a green one, by a solution of verdigris; and a red, by being boiled with Brasil wood, in limewater. The use of ivory was well known in very early ages. We find it employed for arms, girdles, sceptres, harnesses of horses, sword-hilts, &c. The ancients were also acquainted with the art of sculpturing in ivory, of dyeing and encrusting it. Homer refers to the extreme whiteness of ivory. The coffer of Cypselus was doubtless the most ancient monument of this kind in basso-relievo, and we meet with similar instances in the temple of Juno at Olympus, in the time of Pausanias; that is to say, 700 years after it had been built. The ancients had numerous statues of ivory, particularly in the temples of Jupiter and of Juno, at Olympus. In these statues, there was very frequently a mixture of gold. The most celebrated are stated to have been the Olympian Jupiter and the Minerva of Phidias: the former was covered with a golden drapery, and seated on a throne formed of gold, of ivory, and cedar wood, and enriched with precious stones. In his hand the god held a figure of Victory, also of ivory and gold. The Minerva was erected in the Parthenon at Athens during the first year of the eighty-seventh Olympiad—the year which commenced the Peloponnesian war. Pausanias likewise makes mention of an ivory statue of Juno on her throne, of remarkable magnificence, by Polycletus, together with numerous others.

The importation of elephants' tusks into Great Britain in 1831 and 1832 was, at an average, 4,130

cwt. The medium weight of a tusk is about 60 lbs., so that the yearly imports of 1831 and 1832 may be taken at 7,709 tusks, to obtain which 3,854 male elephants must have been destroyed. If to the quantity of ivory required for Britain, be added that required for the other countries of Europe, Asia, and America, the number of elephants annually killed must appear immense, and, it is evident, that the passion for ivory must eventually lead to the extermination of its noble producer.

IVORY COAST; part of the coast of Guinea, between cape Apollonia and cape Palma. See *Guinea*.

IVY (*hedera helix*); a shrubby vine, celebrated from remote antiquity, and held sacred in some countries, as in Greece and Egypt. The leaves are smooth and shining, varying much in form, from oval entire to three or five lobed; and their perpetual verdure gives the plant a very beautiful appearance. The flowers are greenish and inconspicuous, disposed in globose umbels, and are succeeded by deep green or almost blackish berries. It ascends to the summits of the tallest trees, having a stem sometimes three inches in diameter, and also clings to the sides of old walls, rocks, &c. It is found throughout almost the whole of Europe, and in many parts of Asia and Africa.

IWAN, or IVAN; the name of several persons distinguished in Russian history. The most celebrated are Ivan Wasiliewitsch and Ivan II., who laid the foundation of the Russian empire. (See *Russia*.) Ivan V. (or II.), Alexejewitsch, who inherited the crown during his minority, was half brother of Peter I., but, on account of his mental imbecility, took no part in the government. Ivan VI. (or III.) was grand nephew of the former, and son of the grand princess Anna and of Antony Ulrich, duke of Brunswick-Wolfenbuttel. The empress Anna (q. v.) took him, in 1740, out of the hands of her niece, declared him her son, and gave him an apartment near her own. She soon after declared the child her successor, and her favourite Biron was to be his guardian and regent. Biron caused the oath of allegiance to be taken to the prince, and, when he was banished, the parents of the child assumed the reins of government, until the daughter of Peter I., Elizabeth, ascended the throne. The young Ivan was taken from his cradle by soldiers, and shared the fate of his banished and imprisoned parents. He was at first imprisoned at Ivangorod, near Narva, it being intended to keep him always in Russia; but his parents, who were confined at first in Riga, were to be sent to Germany. He never saw them again, but always remained a prisoner in different places, particularly in Western Prussia. In 1756, he was carried to the fortress of Schlussemburg. In 1763, Mirowitch, a nobleman of the Ukraine, who was lieutenant in the garrison of the above fortress, conceived the design of delivering the prince. He induced several soldiers to assist him, and, by means of a forged order from Catharine, he attempted to obtain admission to the fort, but two officers, who guarded him, when they saw that resistance was fruitless, stabbed the unfortunate prisoner, in consequence of an order formerly given by the empress Catharine, that he should be put to death in case of an attempt to deliver him by force. She had already destroyed every proof of the claim of the prince to the throne, and prohibited, under penalty of death, the keeping of coins which could remind the nation of him. The chapel in Schlussemburg, in which he was buried, was afterwards destroyed.

IXION; a king of Thessaly, son of Phlegyas, of Leontes, or, according to Diodorus, of Aëtion by Perimela, daughter of Amythaon. He married De-

daughter of Deioneus, and promised his father-in-law a valuable present for the choice he had made of him to be his daughter's husband. His unwillingness to fulfil his promises, obliged Deioneus to have recourse to violence, and he stole away some of Ixion's horses. Ixion concealed his resentment, invited his father-in-law to a feast at Larissa, the capital of his kingdom, and, when Deioneus was come according to the appointment, he threw him into a pit, which he had previously filled with wood and burning coals. This treachery so irritated the neighbouring princes, that all of them refused to perform the usual ceremony, by which a man was then purified of murder, and Ixion was shunned by all mankind. Jupiter had compassion upon him, and placed him at the table of the gods. Ixion became enamoured of Juno, and attempted to seduce her. Juno was willing to gratify the passion of Ixion, or, according to some, she informed Jupiter of the attempts which had been made upon her virtue. Jupiter made a cloud in the shape of Juno, and carried it to the place where Ixion had appointed to meet Juno. Ixion was caught in the snare, and from his embrace with the cloud he had the Centaurs. (See *Centaurs*.) Jupiter banished him from heaven; but when he heard that he had the rashness to boast that he had seduced Juno, the god struck him with his thunder, and ordered Mercury to tie him to a wheel in hell, which continually

whirls round. The wheel was perpetually in motion; therefore the punishment of Ixion was eternal.

LYNX; daughter of Pan and Echo, or of Peitho (the Suada of the Romans). She inveigled Jupiter into his intrigue with Io. As a punishment, Juno changed her into a bird, called the *wry-neck* (*lynx torquilla*), which still possessed the power of exciting love. When it became desirable that Medea should be enamoured of Jason, Venus gave the hero the magic lynx, and instructed him how to use it in order to inspire Medea with a passion for him. From this time, the lynx became a part of the love-spells among the Greeks. The enchantress tied the bird to a four-spoked wheel, which she turned while she muttered her incantations; or, according to some traditions, she only stretched upon the wheel the entrails of the wry-neck. Another method was, to consume the bird over the coals, on a wheel of wax. The magic wheel was also called *lynx*, because the bird or its entrails were extended upon it. It is sometimes used as a symbol of the art of exciting love in general, and more particularly of unchaste love. In the sequel, the signification of the word *lynx* became different; and it was extended to every charm in poetry and music. In this sense, the lynx went under the name of the nightingale; and it is thus represented on the monument of Sophocles, and in the temple of the Pythian Apollo.

## J

J; the tenth letter, and seventh consonant, of the English alphabet. The character *j* designates very different sounds in the different languages. In English, according to Mr Webster, it represents the sound *dzh* or *edzh*. It has, in fact, the same sound as *g* in *Giles*. In French, it is always sounded like the French *g* before *e* and *i*. In German, it has the sound of the English *y* in *you*. In Italian, it is always a vowel (long *i*), and the character *j* is now little used by Italian printers, except at the end of words, for *i*. In Spanish, it is guttural, a little softer than the German *ch* in *ach*. How nearly the sounds which are expressed by *j* are related, has been shown in the article *G*; and, in the article *I*, it is mentioned, that *i* before another vowel naturally becomes the German *j*. (For other observations, also relating to *j*, see the article *I*.) Though the character *j* is very ancient, it is only in recent times that it has been taken for a consonant, and still more recent is its separation from *i* in dictionaries. In France, the use of *j* for the consonant, and *i* for the vowel, was not established in the middle of the seventeenth century. Among other nations the mixture continued later. James Pelletier, of Mons, is said to have first placed the *j* at the beginning of words which began with this consonant, in his French Grammar (1550). Gille Beys, printer in Paris, imitated him in 1584. In regard to the separation of words beginning with the two letters, in dictionaries, the editors of the French *Grande Encyclopédie*, printed in 1765, did not dare to make it; and English dictionaries, even at the present day, are too often disfigured by the mixing together of *I* and *J*, as well as *U* and *V*. The *Encyclopédie Moderne* calls *j* a *lettre proprement Française*. The other nations adopted it from the French. The Romans, in inscriptions and legends of medals, wrote all words which we write with a *j*, as *Jupiter*, *Justinus*, with an *i*, as *Iupiter*, *Iustinus*. Yet the

character *j* existed several centuries before the fall of the Roman republic. The Greeks had it not.

JABLONSKY; the name of several learned Germans.—*Daniel Ernest* was born at Dantzig, in 1660; became a minister in Magdeburg; in 1686, rector of the gymnasium at Lissa; in 1690, pastor in Königsberg; and went afterwards to Berlin, where he died, in 1742, being then bishop or senior of the Bohemian Brethren in Prussia (Proper) and Great Poland. He endeavoured to unite the Lutherans and Calvinists. Through queen Anne of England he received the dignity of doctor of divinity, from the university of Oxford. He published a number of sermons and several learned works on theology; among which are his *Biblia Hebraica cum Notis Hebr.* (Berlin, 1699); *Jura et Libertates Dissidentium in Polonia; Oppressorum in Polonia Evangel. Desideria*.—His brother, *John Theodore*, was likewise an author.—*Paul Ernest*, son of John, born at Berlin, 1693, was appointed professor of theology, and preacher at Frankfurt on the Oder, where he died, 1757. He wrote many works: *Disquisitio de Lingua Lycaonica* (Berlin, 1714, second edition, 1724); *Exercitatio de Nestorianismo* (ib., 1724); *Remphax Egyptiorum Deus ab Israelitis in Deserto cultus* (Frankfort, 1731); *Dissertationes VII. de Terra Gosen* (ib., 1715, 1736, 4to.); *Pantheon Egyptiorum sive de Diis eorum Commentarius* (3 vols. ib., 1750—52); *De Memnone Græcorum et Egyptiorum* (ib., 1753, 4to., with engravings); *Opuscula ed. J. G. Waler* (4 vols. Leyden, 1804—1813).—*Charles Gustavus*; a naturalist, born 1756, and died at Berlin, 1787, while secretary to the queen of Prussia; particularly known by the work commenced by him—*Natural System of all known native and foreign Insects*, as a Continuation of Buffon's Natural History—of which, however, he executed only vol. 1, the Beetles (Berlin, 1783), and vols. 1 and 2, the Butter-

flies (lb., 1683 and 1784). It was continued and finished by T. F. W. Herbst.

**JACAMAR** (*galbula*, Brisson). These brilliant birds are nearly connected with the kingfishers, from which, however, they differ by the form of their beak and feet. Their plumage has a metallic lustre, which it is almost impossible to imitate by art. They live in damp woods, and feed on insects. Most if not all the true jacamars, are natives of tropical America. There are several species found in India, having a shorter and stouter beak, to which Le Vaillant has given the generic name of *jacamerops*.

**JACK.** Mr Tyrwhitt, in his note upon v. 14,816 of Chaucer, says, "I know not how it has happened that, in the principal modern languages, *John*, or its equivalent, is a name of contempt, or at least of slight. So the Italians use *Gianni*, from whence *zani*; the Spaniards *Juan*, as *bobo Juan*, or foolish *John*; the French *Jean*, with various additions; and in English, when we call a man a *John*, we do not mean it as a title of honour. Chaucer, in v. 3708, uses *Jack-fool* as the Spaniards do *bobo Juan*, and I suppose *Jackass* has the same etymology." To this we will add, that the Germans use *Hans*, their nickname for *John*, for the same purpose; as, *Hans narr*, Jack-fool; *dummer Hans*, stupid Jack, &c. Pennant also, in his *Zoology* (iii. 342), remarks, "It is very singular that most nations give the name of their favourite dish to the facetious attendant on mountebanks. Thus the Dutch call him *Pickle her-ring*; the Italians *Macaroni*; the French, *Jean pot-âge*; the Germans, *Hans wurst*, i. e. *Jack-sausage*; and the English give him the title of *Jack-pudding*."

The name of *Jack Ketch* seems to have become permanently generic for the common hangman.

The names of the *boot jack* and *roasting jack* are derived by Watts, in his *Logic*, from the circumstance that boys (who of course often had the common name *Jack*) were formerly employed to pull off boots and to turn spits; and when instruments were invented for these purposes, the common name of the boys was given to them in sport.

The common *roasting jack* consists of a double set of wheels, a barrel, round which the rope fastened to the pulleys is wound, a perpetual screw, and a fly. Occasionally there is added a multiplying wheel, round which the rope is first wound, before it passes upon the barrel. As this wheel is considerably larger than the barrel, the jack is proportionably longer in running down.

The *smoke jack* is moved by a fan placed horizontally in the chimney, and, being carried about perpetually, by the draught of the fire, requires no machinery for winding it up. Spiral flyers, coiling about a vertical axle, are sometimes used, and occasionally a vertical wheel, with sails like the float-boards of a mill.

*Jack* is also used for a coat of mail, and likewise for the garment worn over it.

*Jack boots* are large boots to cover and protect the legs.

*Jack* is also used for a horse or wooden frame to saw timber upon; for a great leathern pitcher in which drink was formerly put; for the small bowl that serves as a mark at the exercise of bowling; and for a young pike.

*Jack*, in sea language, is a sort of flag displayed from a mast erected at the outer end of a ship's bowsprit.

**JACKAL** (*canis aureus*, Lin.) There is no essential difference between the dog and the jackal, as they will breed together, producing prolific offspring. This species of quadrupeds is very widely extended throughout the warmer regions of the old world. It is found in Africa, from Barbary to the Cape of

Good Hope; in Syria, in Persia, and throughout all southern Asia. It is about two feet and a half in length, and about fourteen inches in height; the length of the tail, about eight inches; the eyes are small; the tail bushy; the head, neck, sides of the belly, thighs, and outer part of the limbs and ears, of a dirty yellow; underneath and on the sides of the lower jaw, and the end of the upper lip, under the neck and belly, and the inner surface of the limbs, somewhat white; the back and sides of the body, to the tail, of a grey-yellow, which is abruptly divided from the surrounding lighter colours; the tail, a mixture of yellow and black hair, the black prevailing at the extremity; the muzzle and nails black. All travellers who have been in the countries where the jackals are found, mention the ravages they commit, and their dreadful nocturnal cries, which, answered as they are by all their companions, produce the most appalling effects. Their voice has often been described as more terrific than the howl of the hyæna or the roar of the tiger, and deprives of repose all hearers who have not been long accustomed to it. The jackal can be tamed with tolerable facility, but always preserves an extreme timidity, which he manifests by concealing himself on hearing the slightest unusual sound, or at the sight of a person whom he is unaccustomed to. This fear is different from that of most wild animals, and he closely resembles a dog in fear of chastisement, for he will offer no resistance when he is touched. The most celebrated commentators on the Bible consider that the 300 animals, to whose tails Samson tied firebrands, were jackals. This opinion is grounded on the great number of these animals found in Syria, and on their assembling in large packs; whereas the fox is comparatively scarce, and is always solitary. The jackal has been popularly termed the *lion's provider*, from an opinion that it rouses the prey for that quadruped. The fact appears to be, that every creature in the forest is set in motion by the fearful cries of the jackals; the lion and other beasts of prey, by a sort of instinct and the call of appetite, attend the chase, and seize such timid animals as betake themselves to flight at the noise of this nightly pack. Buffon gives the following character of the jackal: "It unites the impudence of the dog with the cowardice of the wolf, and participating in the nature of each, is an odious creature, composed of all the bad qualities of both."

**JACKDAW** (*corvus monedula*, Lin.) This bird is one of the crow kind, and has been celebrated for its copious vocabulary and garrulous habits. It is about thirteen inches in length, with black bill; white eyes; the hinder part of the head and neck of a hoary-grey colour; the rest of the plumage, of a rich glossy black above; beneath dusky; the legs are black. The jackdaw is very common in Britain, where it remains the whole year; in France, and various other parts of the continent of Europe, it is migratory. It is gregarious, frequenting old towers and ruins, where it builds its nests. The female lays five or six eggs of a greenish colour, and is exceedingly assiduous in her attention to her young after they are hatched. These birds principally live on worms and the larvæ of insects, but they also appear to be capable of taking fish. Bingley states that he was witness to an instance where a jackdaw was very successful in this mode of obtaining food. It is easily tamed, and may be taught to pronounce many words with little difficulty. The jackdaws are notorious thieves, not only stealing food, but appearing to be particularly fond of shining substances, as money &c., and have frequently occasioned suspicions of theft in persons who were afterwards proved innocent. So far do they carry this propensity, that they

have been known to carry off spectacles from persons who were reading.

**JACKSON**; the name of numerous counties and towns in the United States of America. The Jacksons, Jacksonvilles, Jacksonsontowns, Jacksonboroughs, &c., are chiefly in the Western States, and have mostly received their names since general Jackson's successful defence of New Orleans.

**JACKSON, WILLIAM**, a musical composer, was born in 1730, at Exeter, and received the rudiments of a classical education, with a view of his following one of the liberal professions. His taste for music displayed itself, however, so decidedly while he was yet a youth, that his friends were induced to place him under Travers, the organist of the cathedral belonging to his native city. Having passed two years in the metropolis, where he availed himself of the instructions of some of the best musicians of his day, he returned to Exeter in 1750, and, succeeding eventually to the situation of organist, there passed the remainder of his life. In 1782, he published two octavo volumes, containing *Thirty Letters on various Subjects*, which went through three editions. He also printed, in 1791, some *Observations on the present State of Music in London*. His musical compositions are still justly popular, and are distinguished by chasteness of conception, ingenuity, and truth of expression. He died in 1804.

**JACOB**; the son of Isaac, and the grandson of Abraham; the last of the patriarchs, and the true ancestor of the Jews. In his mother's womb, he quarrelled with his brother Esau, whom he held by the heel as he came into the world. Hence his name, *Jacob* (heel-holder). Being the object of maternal indulgence, he was gentle and weak, and was disposed to advance himself by cunning rather than by courage. While a youth, he purchased of his brother (who returned home weary and hungry from the chase) his birthright for a mess of pottage, and, at the instigation of his mother, disguised like Esau, he obtained from the blind and infirm Isaac, the blessing of the first-born, on which depended the inheritance of the promise made to Abraham. He was obliged to flee from the anger of his brother; and, on his way to Laban, his mother's brother, he received the first intimation that the inheritance of the divine promise had devolved on him. He saw in a dream a ladder reaching from heaven to earth, and angels ascending and descending upon it, and the guardian God of his family, whom he supposed to be in the tent of Isaac, conferred on him the blessing of Abraham. After this vision, he firmly believed that Jehovah had chosen him to be the father of a great people. This belief, and the love of Laban's daughter Rachel, were his consolation during the bitter years which he was obliged to devote to the flocks of his uncle, in order to obtain his mistress. After having served seven years, he found in his veiled bride Leah (whom he did not love), the elder sister of Rachel, and in order to obtain Rachel, he was obliged to serve seven years more. Besides these fourteen years, he served six years for a herd, and, after having repaid the deceit of his father-in-law, by an artifice which much increased his possessions (*Gen. xxx. 27—43*), he departed privately with his wives and children, and property. Laban pursued him, and scarcely had Jacob appeased him, when, after twenty years' absence from home, he met the followers of his brother Esau. In this dilemma, Jacob sought relief in prayer, and a man wrestled with him all night until the morning dawned. Jacob came off victorious, though with a lame thigh, and he was called by his guardian God, whose hand he saw in this event, *Israel*, i. e. the hero of God, in remembrance of the contest. This afterwards became the

title of his house, and the Hebrews (*q. v.*), from him, are called *Israelites*, i. e. *strong* and *stout*. Jacob now went forth with more confidence to the much dreaded meeting with his brother, and appeared his rough, but noble nature, by his submission. His return to his father's tent made a great change in the character of Jacob. His cunning and avarice appeared to him, as it has since to his descendants, the necessary means for making his way through the difficulties of his dependent situation. Now that he had become rich, and uncontrolled master of his possessions, he showed himself worthy of his father; and if he did not resemble Abraham in greatness and power, he did in piety and tender love for his children. Yet through them he was destined to suffer the greatest afflictions. As he had two lawful wives, and, according to the custom of the country, two concubines (Bilhah and Zilpah), with twelve sons and a daughter, he could not escape domestic troubles and dissensions. His beloved Rachel died soon after his return home. A prince of the Hivites violated his daughter Dinah, and his sons revenged the injury by plundering and murdering that people. He could neither prevent this nor the incest committed by Reuben with Bilhah. Humiliation and repentance for the sins of his youth seemed now his lot. But his greatest affliction was the loss of his favourite son Joseph, whose brothers, full of envy against him, had sold him to a caravan of Ishmaelite merchants, and brought his coat, stained with blood, to their father, as a proof that he had been devoured by wild beasts. This event decided the destiny of the house of Israel. Joseph (*q. v.*) subsequently became, in consequence of his wisdom, the highest officer at the court of Pharaoh, and, in this capacity, recognised his brothers when they came to Egypt to purchase corn, pardoned them, and called the whole house of his father out of Canaan to dwell in a fruitful region of Egypt. The aged Jacob again embraced his favourite son, whom he had, for many years, supposed dead, and enjoyed, under his protection, a happy old age. A short time before his death, Israel collected his sons around his bed, and pronounced over each of them a blessing full of prophetic anticipations of the characters and future fate of his descendants. He bestowed the privileges of the first-born on his fourth son, Judah, Reuben having forfeited them by the crime above-mentioned, and Simeon and Levi by the murder of the Hivites. To his grandsons, Manasseh and Ephraim, the sons of Joseph, he gave privileges equal to those of his sons. The descendants of Judah composed the most powerful tribe among the Hebrews, who were hence called *Jews*. In conformity with Jacob's last will, Joseph buried him in the tomb of Abraham, before Mamre in Canaan.

**JACOBI, JOHN GEORGE**, a German poet, was born at Dusseldorf, 1740, studied theology, in 1758, at Gottingen, and, later, in Helmstadt, then became professor of philosophy and eloquence in Halle, where he published the *Iris* (1774 to 1776, three volumes), a periodical for ladies. Joseph II. appointed him professor of belles-lettres in the university of Freyburg in the Brisgau (1784). From 1795 to 1800, he published the *Uebersüssiger Taschenbuch*, and from 1803 to 1807, the *Iris*. An edition of all his works was published at Zurich, in seven volumes. He died Jan. 4, 1814.

**JACOBI, FREDERIC HENRY**; a distinguished German philosopher, younger brother of the preceding, born at Dusseldorf, in 1743. His father intended him for a merchant. He early showed a religious turn, which, on his being sent to Frankfort as an apprentice, exposed him to ridicule. He therefore soon went to Geneva, where his mind was cultivated by intercourse with the most distinguished scholars, and

by the study of the best productions of French literature. In consequence of the taste he had acquired for letters, he returned home with reluctance, in order to take charge of his father's business. He soon after married a lady of Aix-la-Chapelle, adorned with the finest qualities of mind and person. After having conducted the business for some time, an appointment at court was conferred on him, which relieved him from any further mercantile engagements. His brother introduced him to an acquaintance with Wieland, and he soon appeared as an author. In 1779, he was called to Munich, but soon fell into disgrace on account of his exposure of the abuses of the Bavarian system of customs. More of his writings appeared at this time, and his summers were spent at Pempelfort, in a charming country seat, which he had built. But the death of his wife interrupted this tranquil and happy life. He now applied himself, with renewed zeal and industry, to his studies, encouraged by a journey to Weimar, where he saw Goethe again, and became acquainted with Herder. His letters on Spinoza appeared in 1786, from which time his mind was much occupied with metaphysical speculations on religious subjects. As the influence of the French Revolution extended itself, he went from Dussekendorf, in 1794, to Holstein, the native country of his father, and lived part of the time at Wandsbeck and Hamburg, and partly at Eutin. In 1801, he went to Paris, and returned to Eutin, where he intended to end his days; but, in 1804, having received an invitation to the new academy erected at Munich, he was induced to accept it on account of the loss of a considerable part of his fortune by the misfortunes of his brother-in-law. He was made president of the Bavarian academy, and retired from office at the age of seventy years, retaining, however, his salary. His last days were occupied with the collection of his works. He died March 10, 1819.—Jacobi's works are rich in whatever can attract elevated souls, yet the opinions respecting him are very different. He has been called the *German Plato*, on account of the religious glow in his metaphysical writings. But, whatever opinions may be entertained respecting his philosophy, all admit that he was a most exemplary man, truly revered by all who had the good fortune to be acquainted with him. His philosophy, among other traits, is characterised by an aversion to systems, all of which, he maintains, when consistently carried out, lead to fanaticism. His views were opposed to those of the dogmatic Mendelssohn, the critical Kant, the idealizing Fichte, and the pantheistic Schelling. Of his works, we mention Edward Allwill's *Collection of Letters* (Königsberg, 1792); *Woldemar*, a philosophical novel (Königsberg, 1794); *Letters on the Doctrine of Spinoza* (Breslau, second edition, 1786); his work on Mendelssohn's charges against these Letters (Leipsic, 1786); David Hume on Belief, or Idealism and Realism (second edition, Ulm, 1795); *Sendachreiben an Fichte* (Hamburg, 1790). His works were published by Fleischer (Leipsic, in six volumes), to which is to be added his Correspondence (published by Fr. Roth, in two volumes, 1825 and 1827). Schlegel's review of Jacobi's *Woldemar* (in volume 1, page 1 to 46 of *Charakteristiken und Kritiken*) deserves the attention of the student of Jacobi. His dispute with Schelling was carried on with considerable animosity. It gave birth to Schelling's *Denkmal der Schrift von den Göttlichen Dingen* (Tübingen, 1812).

JACOBINE MONKS. See *Dominican*.

JACOBINS. The club of the Jacobins is one of the most surprising phenomena in history. That, in a civilized nation, so large a body of men could be found, uniting rare energy with execrable vice, political madness, and outrageous cruelty, committed

always in the name of virtue, is an historical phenomenon of the highest interest. It is of great importance for the historian to know this period, but it requires extensive study to understand thoroughly the proceedings of this club and their causes. In the article *France*, division *France before the Revolution*, the deplorable state of that country before that event is set forth. The great mass of the people was totally uneducated and grievously oppressed, and the whole political organization so rotten, that, once touched, it necessarily fell to pieces. The religious state of the country was not unlike the political. The church was too corrupt to withstand the bold attacks of reformers, enthusiastically devoted to their new systems. The court, and the higher classes in general, had for centuries set an example of gross immorality to the people, which had produced its natural effects in vitiating their character. The opponents of the church and aristocracy, who came into power upon the overthrow of the old order of things, were wholly unacquainted with the practical administration of government, and had nothing to guide them but general philosophical principles. Under these circumstances, the excesses which the French people committed, when left to govern themselves, are matter of sorrow rather than wonder. The Jacobin club had the following origin. Before the breaking out of the revolution, particularly after the American revolution, political societies were formed in Paris (where *bureaux d'esprit*, or associations for the discussion of literary subjects, had previously been common), modelled after the London debating societies, in which political subjects were debated, and the members of which were almost universally inclined to republicanism. The example of Great Britain and the United States of America was before the French. Some distinguished members of the first national assembly, principally from Bretagne, and commoners, on account of the opposition of the privileged classes and of the court party, saw the necessity of acting in concert, and of preparing for the measures of each day by previous deliberations; for which purpose they assembled in the evenings at the house of one of their body, or held a *cercle*, as we should term it. Among them was count Mirabeau, who, when the Jacobins subsequently passed the constitutional limits, seceded from them, and even denounced them. The same was the case with La Fayette. But, when both perceived that they could effect nothing in the national assembly without the consent of the Jacobins, they returned to the club, in order to influence the assembly by this means. Meanwhile Mirabeau died, April 2, 1791. The monarchical club, under Clemeut-Tonnerre, which opposed the arrogance of the Jacobins, was menaced by the mob, Jan. 27 and March 28, 1791, and finally dispersed by violence. The Jacobins now became sensible that the pike-men were their real auxiliaries. The flight of the king still more exasperated the most zealous of them, and, after the close of 1792, their principles were so exaggerated, that the original Jacobins were now expelled from the club as royalists or *modérés*; for instance, Fréron, Legendre, and others. Whatever was resolved upon in these and similar meetings, was supported by all the members of the club in the national assembly. The Bretons soon admitted a greater number, in order to carry through their opinion with more certainty. Thus the members became pledged to a certain law of conduct on each question, before it was brought forward in the general assembly of national representatives, and a party was formed which, in the assembly, always voted together. Besides the intolerance towards those of different opinions, which afterwards degenerated into political proscription and

persecution, personal motives had a powerful influence on the members. The private house in which they first assembled soon became no longer capable of containing the number of *friends of the revolution*, as they at first called themselves; they therefore chose for their place of meeting, at the end of 1789, the church of a suppressed Jacobin monastery, in the street St Honoré, in the centre of Paris. This was the origin of the name *Jacobins*, though they continued for a time to term themselves the *friends of the constitution*. Their external symbol was a red cap; afterwards, a dirty dress was the token of their *sansculottism*. The revolution proceeded rapidly, and, in all the large and small towns, and, in 1793, even in some villages, similar societies were formed, which the mother society at Paris rendered dependent on itself; and thus it became enabled to direct the public opinion of all France. In 1792, the leading club, in which sometimes more than 2500 members convened, kept up a correspondence with more than 400 affiliated societies, and the number of Jacobins in all France was estimated at about 400,000. It is unnecessary to designate the principal members of the mother society, as it is well known that all men of any note, who played, or wished to play, a part in the revolution, were Jacobins. The influence which Paris, more than any other European capital, exerts over the country, greatly increased the power of the Jacobins there. Whatever they agreed to propose in the national assembly, however daring it might be, they were sure of the assent of the other popular societies, from their connexion with the principal members of the other clubs. This naturally induced ambitious individuals, even of the higher classes, to join it, and to renounce the privileges of their order, with a view of obtaining greater consequence in the new state of things. The exaltation of the revolutionary spirit was so rapid, and so much dissension was excited among the revolutionists by the intrigues of the opposite party, aided by foreign influence, that the boldest characters formed a smaller club, which, from its place of meeting, in the church of the Franciscan friars, was called the *club of the Cordeliers* (q. v.), and which was joined by all the *exaltés*, as they were denominated. This was the proper field for the daring Danton, and here the monster Marat, from 1789 editor of the *Friend of the People*, found credence to his wild and criminal maxim, that the end justifies the means. Here *sansculottism* was fully developed in its violence, its hatred of religion, and contempt of morality and law. The circumstances of this agitated period required the boldest measures, and the most unscrupulous men were of course the most daring. The ex-Capuchin Chabot, Anacharsis Cloots, Collot d'Herbois and others carried their temerity to the highest pitch in their public speeches. As the Jacobins and the combined Orleanists and Brissotists, who laboured to overthrow the crown, the former for the duke of Orleans, and the latter to establish a republic, took the right side of the apartment of the national assembly; the members of the other popular societies placed themselves on the left. Few, however, attended the assembly for the purpose of deliberation, their purpose being only to vote for what had already been agreed upon. The Jacobins and other similar clubs therefore adopted the forms of the national assembly. Presidents and secretaries were chosen, the order of the day determined, resolutions passed by a majority of votes, and seats or tribunes assigned to the audience. To such popular societies the national assembly gave a legal existence in the constitution which it drew up. From this time the Jacobin club exercised a perfect tyranny over it. Whenever the Jacobins were not sure of the majority in the assembly, their followers filled the tribunes of

the hall of the deputies, and, by their disorderly conduct, and frequently by loud threats against individual members, discouraged all opinions or resolutions which did not coincide with those of their party. This was especially the case with respect to the king, against whom the Jacobins and Cordeliers, particularly since 1791, had circulated the grossest calumnies. The democratic Cordeliers therefore joined with the Orleans party, which laboured unwittingly for the objects of the republicans, by uttering the most slanderous charges against the king and queen, and by having the lowest of the rabble on their side, and partly even in their pay. This was the reason that a popular insurrection opposed with violence, April 18, 1791, the departure of the king to St Cloud, where he wished to spend the Easter holidays. Even the national guard, in disobedience to the order of the commander, La Fayette, refused to escort the king, who was already seated in the carriage, through the multitude. The party of the king's enemies was the more powerful, as the more moderate members had withdrawn from the Jacobin club, and the Cordeliers had again formed a junction with it, June 21. The latter, however, continued their meetings at the Capuchin monastery, in order by being prepared and united, to manage the deliberations of the Jacobin club. After the flight of the king, June, 21, 1791, they made use of the popular hatred against him, and loudly demanded the deposition of Louis and the erection of a republic. But the more moderate party, who for a long time were called *Fevillants*, from the place of their meeting, opposed their designs, and the insurrection of July 15—17, 1791, failed of its object. But, on the other hand, the retired deputies of the constituent assembly failed of dissolving the Jacobin club, before the close of its own session. When the legislative assembly, the new delegates to which had been chosen almost entirely under the influence of the Jacobins, had opened its session, Oct. 1, 1791, the friends of the king, among whom the Girondists (q. v.) were conspicuous for talents, maintained for some time the majority against his enemies (the Cordeliers), even in the Jacobin club, so that the leaders of this club—Danton, Marat, Robespierre—were obliged to disguise their projects. But their influence was augmented by the circumstance that the mayor of Paris, Pethion, and with him the municipal authorities of Paris, composed of Jacobins, espoused their cause. Even the moderate Jacobins, and among them some of the royal ministers, inclined to the party of the enemies of the king. Thus, by the popular insurrection of May 29, 1792, they obtained a resolution of the national assembly, requiring the king to disband the body guard, decreed to him by the first assembly of the nation; but they were unable, by the insurrection of the suburbs of St Antoine and St Marcell of June 20, to compel the king, whom only four Swiss grenadiers protected, against the attacks of the furious multitude, to revoke the veto that he had affixed to two resolutions of the national assembly; but they gained a majority of the assembly to protect from condign punishment the authors of this tumult—Pethion, Manuel and others. Meanwhile, the Jacobins, offended by a note of the Austrian minister of state, prince Kaunitz, had effected, against the will of the Cordeliers, a declaration of war against Austria, April 20, 1792; and Jacobinism soon displayed its influence in the selection of generals, in the proclamations, and in the disposition of the armies, so that neither La Fayette, in 1792, nor Dumouriez, in 1793, could excite the army against the Jacobins. But all the occurrences subsequent to June 20—the arrival of the confederates from Brest, Marseilles, and other places, July 13; the attack of the Tuil-

ries on the night of Aug. 9; the carrying of the king and his family as prisoners to the Temple by the municipal officers of Paris, Aug. 13; the massacre of the prisoners, Sept. 2—7, who were murdered without trial; the choice of new members of the convention, in September of the same year; all the acts of the national convention, from Sept. 21, 1792, to May 20, 1795, even after the ninth Thermidor (July 28, 1794), especially the execution of the king; and, finally, the establishment of the revolutionary tribunal, March 9, 1793—may be regarded as more or less effected by the Jacobins. The Jacobins were divided into two parties; agreeing as to the end, they thought differently concerning the means. Tallien, who overthrew Robespierre, was as true a Jacobin as the latter was. The enthusiastic suspected the moderate. The victory was long doubtful. Finally, the moderate were vanquished. The genuine republicans—the Girondists, or the party of the Plain—were subdued May 31 and June 2, 1793, by the more violent Jacobins, or Mountain party.\* These again were governed by the Maratists or Cordeliers, who ruled in the Jacobin club with iron sway, under the duumvirate of Robespierre the Incorruptible, and Danton, the formidable creator of the revolutionary tribunal, with Marat for an assistant. On the other hand, the moderate party was victorious in the provinces, at Marseilles, Bourdeaux and Lyons. The south took up arms against the Jacobin convention. But the Mountain party succeeded in depriving the convention of power, and, on the proposal of Billaud de Varennes, the constitution gave way to the reign of terror (from August, 1793, to July, 1794). But the triumph of Jacobinism was the establishment of the committee of safety which completed the reign of terror under Robespierre, and, by means of the revolutionary armies, suppressed rebellion with fire and sword in Vendée, and in the south. Cities like Lyons, Marseilles, Toulon, were to be demolished, and all Vendée to be transformed into a great field of blood and ashes. Fourteen armies, the guillotine and an iron stubbornness, finally won the victory for the system of terror. France, it was said (and, for the moment, it was true), wanted only iron and bread. Not till the dictator Robespierre had perished under the guillotine, July 28, 1794, and with him 104 of his partisans, together with the municipal council of Paris, did the convention recover its authority. It denied to all popular assemblies any interference with the government. In vain did the Jacobin club attempt an insurrection, Nov. 11, 1794, in order to tear the monster Carrier from the sword of the law. This was its last struggle. The citizens of Paris surrounded the hall of the Jacobins till the military arrived and dispersed the meeting: Legendre closed the hall. The finishing stroke was given to this victory by the decree of the convention, that the Jacobins should not renew their meetings. But their principles survived their defeat. They took advantage of the general

famine to stir up a rebellion, April 1, and May 30—23, 1795. The last one brought the convention to the verge of dissolution. A member named Fernal was murdered; all the rest took to flight, except fourteen of the former Mountain party, who immediately passed a number of decrees conformably with the will of the Jacobins. Not without difficulty were the Paris committee able to quell this bloody tumult. By the disarming of the *faubourgs* St Antoine, the Jacobin party lost its principal support, as it had already lost its boldest orators—Barère, Collot d'Herbois, and Billaud de Varennes, who were transported to Cayenne, April 2, 1795. Of the fourteen deputies who had desired to restore the system of terror, six killed themselves after their condemnation, July 17, among whom was the talented Romme. Even in Toulon, the Jacobins were at first victorious; but the troops of the convention occupied the city again, May 29. Thus the Jacobins prepared, May 20, their own downfall. Courts-martial condemned them every where to death as terrorists, and the fury of the prevailing moderate party, as it was called, outstripped the demands of justice. The constitution soon after drawn up, June 23, 1795, and the directorial government, which was actually commenced October 27 of the same year, suppressed the last struggles of the Jacobins and terrorists, till the execution of Babeuf and his associates, May 25, 1796. But, when the constitution of 1795 seemed annihilated by the victory of the directors, Barras, Rewbel, and Laréveillère, on the 18th Fructidor (September 4, 1797), Jacobinism arose anew. It sought to penetrate into the offices of the legislative councils, but found nowhere a point of union. Many of the party soon denounced republicanism. Most of them became the friends of Napoleon.

Much has been written respecting the Jacobins, and the supporters of old institutions in Europe have been in the habit of branding with the name of Jacobinism every attempt to promote the cause of liberal principles. See, for instance, Robinson's *Proofs of a Conspiracy against all the Kingdoms and Governments of Europe*, &c. (fourth edition, London, 1798); and the prolix but empty accusation of the abbé Barruel, founded on Robinson's work, and on similar emissions of party spirit, and directed against philosophy and secret societies in general—*Mémoires pour servir à l'Histoire du Jacobinisme* (five volumes, Hamburg, 1800); also the *Lettres d'un voyageur à l'abbé Barruel, ou nouveaux Documents pour les Mémoires* (London, 1800), written in a similar spirit. To learn the true character of the Jacobins, the debates of the national assembly should be studied.

In 1814, the violent ultras (q. v.) were called *white Jacobins*; whilst, in turn, the adherents of Napoleon were called *red Jacobins*. As the anarchy, before the revolution of 1792, called the people, in contempt, *la canaille* (q. v.), so, before the revolution of 1830, every liberal, however loyal he might be, was called a *Jacobin*. Immediately after the revolution of 1830, popular societies were formed, or at least appeared openly, two of which soon gave uneasiness to government, and their proceedings were subjected to a judicial investigation. The names of these societies were *L'ami du peuple* and *Aide-toi et Dieu t'aidera*. They were abolished.

JACOBITES; Monophysite Christians in the East, who, oppressed and dispersed amidst the religious contests of the sixth century, were united by a Syrian monk, James (Jacobus) Bardai, or Jacobite (578), during the reign of Justinian, into a distinct religious sect. Out of gratitude to their founder they called themselves by his name, and had in Syria, Egypt, and Mesopotamia, numerous communities, with bishops and patriarchs. On account

\* The common fate of parties in periods of great popular commotion, whose exasperated feelings lead them to put the worst construction on each other's doings, was never more clearly exhibited than in the case of the Girondists and Jacobins. Whilst the Girondists accused the Jacobins of being in the pay of foreigners, of having admitted the British into Toulon, &c. (the *Memoirs of Brissot* are full of these charges), the Jacobins accused the Girondists of being for the king, &c. It must be acknowledged that the Girondists—as virtuous a party as perhaps ever existed—were merely theoretical politicians, and never could have saved France, in the state in which it then was. They made the virtue of the nation the basis of their political edifice—a mistake which never could have been more serious than at that very time. Both parties, it was evident, could no longer exist together.

of their separation from the Catholic church, they were glad to obtain the protection of the Saracens, who possessed themselves of the East in the middle of the seventh century. The Egyptian Jacobites, having abused the indulgence granted them by the Saracens, suffered a persecution in 1352, after which, being much diminished in numbers, and restrained in the exercise of their religion, and being gradually separated from their Asiatic brethren, they formed a distinct sect, which exists at this day in Egypt, under the name of *Copts* (q. v.). Internal disputes and political causes occasioned a separation, about the same time, of the Abyssinian and Armenian Monophysites, from the great body of the Jacobites; and, after numerous attempts by the popes to bring them over to the Roman Catholic church, they still maintain themselves as an independent sect in Syria and Mesopotamia, and consist of about thirty or forty thousand families. These Jacobites are governed by two patriarchs, appointed by the Turkish governors, one of whom, with the title of the *patriarch of Antioch*, has his seat at Diarbekir or Aleppo; the other, the Syrian, resides in the monastery of Saphran, near Mardin, and governs the Mesopotamian societies. Circumcision before baptism, and the doctrine of the single nature of Christ (hence their name *Monophysites*), are common to them with the Copts and Abyssinians; but, in other respects, they deviate less than the other Monophysites from the discipline and liturgy of the orthodox Greek church.

*Jacobites.* In Great Britain, this name was applied to the adherents of James II. (who was deposed 1688) and his posterity, and in particular to the non-jurors, whose separation from the English church consisted merely in their refusal to take the oath of allegiance to the new king; and who had their own meetings, for the purpose of praying for the Stuart family. They were most numerous in Scotland, and were very much lessened by the defeat of the Pretender (1745); and when, at length, he died at Rome (1758), they began to pray for George III.

JACOBS, FREDERIC CHRISTIAN WILLIAM, was born at Gotha, in Saxony, 1764, studied theology in Jena, in 1781, and, in 1784, went to Göttingen, where he abandoned his theological studies, in order to devote himself to philology. In 1785, he became a teacher in the gymnasium of his native city, where he published several works, and, in conjunction with several learned friends, undertook the *Charactere der Dichter aller Nationen* (7 vols.), as a sequel to Sauer's *Theorie der Schönen Wissenschaften*, the continuation of which was prevented by the death and separation of the contributors. Among his other works are the following: *Bion and Moschus*, in 1795; in 1796 and 1797, *Exercitationes criticae in Scriptores veteres* (2 vols.). His *Emendationes in Anthol. Græc.* (1793) was followed by a reprint of the part of the *Analecta* of Brunck, which belongs to the Anthology, with indexes (Leipsic, 1794 to 1814, 8 vols.). His *Tempe* (Leipsic, 1803, 2 vols.) was prepared contemporaneously with his commentary on the Anthology, which he finished in 1803. Of his *Elementarbuch der Griechischen Sprache*, two volumes had appeared when he was appointed (1807) professor of ancient literature in the Lyceum in Munich, and member of the new Bavarian academy. In Munich, he completed the 3d and 4th vols. of his Greek *Elementarbuch*, and, in three years, returned to Gotha, where he was appointed chief librarian and superintendent of the cabinet of coins. Here he made out a catalogue of the valuable library, and published the Greek Anthology, from the only MS. which has been preserved, under the title *Anthologia ad Fidem Codicis Vaticanæ edita* (Leipsic, 1813 to 1817). The number of his philological publications

is very great, besides several works of a different character, as *Allwin und Theodor, Rosaliens Nachlass, Die beiden Marien*, School for Women (7 vols., 1827), and *Tales* (5 vols., Leipsic, 1824—1827), &c.; and few writings are so well adapted, particularly for young females, as his. The first volume of his Greek Reader had passed through seven editions in 1819; and selections from the work have been introduced, as a text book, into Britain and America; in the latter, under the title of the Greek Reader, edited by E. Everett (2d edit., Boston, 1829). In connection with Döring, he also published a Latin Reader.

JACQUIN, NICHOLAS JOSEPH, baron of; a celebrated botanist, who was a native of Leyden. He was born in 1727, and studied medicine at Antwerp and Louvain. The emperor Francis I. sent him to the West Indies, to collect curious plants for the gardens of Schonbrunn. He commenced his voyage in 1754, and returned to Germany, after an absence of six years, with a rich store of plants from the Antilles, Jamaica, St Domingo and Curacao. He published, in 1760, an account of his researches, and the collections with which he had enriched the gardens of Schonbrunn, and of the university of Vienna, which were under his direction (*Historia Stirpium Americ.*). Two years after, appeared his catalogue of plants growing in the neighbourhood of Vienna, and, in 1773, a magnificent work, entitled *Flora Austriaca*, fol., with 500 coloured engravings. He engaged in the practice of medicine in the Austrian metropolis, and also occupied the professorships of chemistry and botany in the university of that city. He was created a baron in 1806. He died Oct. 24, 1817. A list of his numerous scientific publications may be found in the *Biog. Univ.* and *Biog. Nouv. des Contemp.*

JAFFA; the ancient Joppa, a town of Asiatic Turkey, in Syria, in the pachalic of Damascus, sixteen leagues N.N.E. from Ramé or Gaza; twelve leagues N.W. of Jerusalem, and twenty-two leagues S.S.W. of St Jean d'Acre, on a tongue of land advancing into the Mediterranean; lat. N. 32° 3' 25"; lon. E. 34° 46' 18". Jaffa is situated on a hill, and is surrounded with a strong wall of from 12 to 14 feet in height. The port is defended by two forts. There are several mosques, and three convents. Vessels cannot approach the city nearer than a quarter of a league, on account of the breakers. Several consuls of European powers reside here. Pilgrims who proceed to Jerusalem frequent this city much. It contains 3650 inhabitants. The environs of Jaffa produce fruits of the best quality, particularly fine and large oranges. The Greeks and Phœnicians considered Jaffa as a very ancient place, and it certainly existed 1500 years before the Christian era. *Iapho* was the Phœnician name. Joppa is mentioned several times in the Scriptures. During the crusades, Joppa became the capital of a small country of the same name. Saladin burnt it, but St Louis re-established it.

Jaffa is connected with two remarkable circumstances in the life of Napoleon: one, the bold exposure of his life by traversing the plague hospitals, and touching the poisonous sores, to give courage to his soldiers; the other, the "massacre at Jaffa." This place contained a garrison consisting of Turkish and other soldiers, in the employ of Djézar Pacha, when general Buonaparte attacked it. A breach was made in the walls, March 7, 1799, when, according to the rules of war, the Turkish commandant was called upon to surrender; instead of which, he cut off the head of the messenger. The fortress was taken and pillaged. Buonaparte, in his letter to the directory, 23d Ventose, year VII. (March 13, 1799),

says, "At five o'clock we were masters of the city, which, during twenty-four hours, was exposed to pillage and all the horrors of war, which never appeared to me so hideous." (See *Mémoires de Napoléon, écrits par le Général Baron Gourgaud*, vol. 2, p. 376.) Three thousand men, says the duke of Rovigo, in his *Mémoires*, were made prisoners, the greater part of whom were the same soldiers to whom life and liberty had been granted at El Arish, under the condition not to bear arms against the French within a year, and to proceed to Bagdad. At the same time, news was received that the Porte, after having put in irons all the French agents, had declared war against France, and assembled an army at Rhodes, which was to be sent to Egypt. To give liberty again to these prisoners, was to send recruits to the Turks; to conduct them to Egypt under an escort, would have weakened the small army under Buonaparte's command at Jaffa. A council of war was held, and it was determined that all should be put to the sword. Even Bourrienne, who had accompanied Buonaparte in the expedition to Egypt, states in his *Mémoires*, that the massacre of the remnant of the garrison of Jaffa was the result of the deliberations of two councils, at which M. de Bourrienne himself was present, and in which "horrible act of necessity," if he had been privileged to vote, he would have concurred, believing it to be justified by the scarcity of provisions, which were all required for the French army, and the smallness of its numerical force in the midst of a country where every individual was an enemy. The Egyptians were not, as has been often asserted, previously separated from the other prisoners. As to the poisoning those affected with the plague, M. Bourrienne, whose statements, however, cannot always be admitted unqualifiedly, says, that he knows that the order for poisoning was issued; but Napoleon, according to Las Cases, told him that no opium was administered. Las Cases also gives, as the result of his own inquiries in Paris, among the principal actors on this occasion, that the proposal was made by Buonaparte to the chief physician, who declined; that no order was given to administer opium; and that there was not a grain of it at this time in the army. *Mémorial de St. Helene*, Paris, 1823—4, page 268, et seq.

JAGONELLES. See *Poland*.

JAGEMANN, CHRISTIAN JOSEPH, librarian of the duchess Amelia of Weimar, was born 1735, in Dingelstadt, and destined by his Catholic parents for the cloister. Having escaped from the Augustine monastery, he was afterwards sent to Rome, as a penance. He lived there several years, and acquired that taste for Italian literature which made him a distinguished writer on the fine arts and literature of Italy. He is the author of a *Description of Tuscany*; a *History of Arts and Sciences in Italy* (3 vols. 8vo.); a *Magazine of Italian Literature* (8 vols. 8vo.); the *Life of Galilei*; an *Italian and German Dictionary* (2 vols. 8vo.); and an *Italian Grammar and Chrestomathy*. He died February 4, 1804.

JAGGERNAUT. See *Juggernaut*.

JAGO, Sr; the Spanish for *St James*. See *James, St*.

JAGO, Sr; one of the largest of the Cape Verd islands, and one of the best cultivated, and most fertile, is about sixty miles in circumference. The people in general are of a mixed colour, except the officers of government and most of the priests. Cotton is produced in abundance, and handsome goods are made of it, of which no small quantity is exported. The chief fruits of the island, besides a profusion of plantains, are grapes, citrons, lemons, oranges, musk and water-melons, limes, guavas,

pomegranates, quinces, custard-apples, papas, &c. The chief towns are St Jago and Praya. Lon. 22° 40' W.; lat. 15° 4' N.; population, 20,000.

JAGO DE CUBA, Sr; a town in the island of Cuba, near the south coast; lon. 76° 5' W.; lat. 20° 30' N. It is situated in the interior of a bay, on a river of the same name, about six miles from the sea, and was long considered as the capital of the island, but is much reduced from its former splendour. It is handsomely built, and contains a college, an hospital, a cathedral, two or three convents, and sixteen primary schools. It has a large trade, principally a sugar and tobacco. It has a good harbour, defended by a castle called *El Morro*. Population, as given in the *Cuadro Estadístico de Cuba* (Havana, 1825), is 26,738. Its situation is unhealthy.

JAGO DE COMPOSTELLA, Sr. See *Compostella*.

JAGO, Sr, or SANTIAGO; capital of Cuba. See *Santiago*.

JAGUAR (*felis onca*, Lin.) This name, having been applied to several different species, is apt to create some degree of confusion. The jaguar bears the same rank among the animals of the new continent as the tiger among those of the old. (In the whole upper part of its body, it is of a bright yellowish fawn colour, which passes, on the throat, body, and inside of the legs, into a pure white. On the ground, the head, limbs, and under surface are covered with full black spots, of various sizes, and the rest of the body with annular patches, either with a black point in the centre, or formed of small black spots arranged in a circular form. This animal is found in the swampy forests of South America, especially in the neighbourhood of large rivers, which he swims with great ease. Of his power of swimming, as well as of his extraordinary strength, the following circumstance, related by D'Azara, will give some idea:—A jaguar, after having attacked and destroyed a horse, carried the body of his victim to the bank of a broad and rapid river, about sixty paces distant, over which he swam with his prey, and then dragged it into the adjoining wood. Possessed of such tremendous powers, this animal is the dread of the inhabitants of the country he infests. It is seldom, however, that he attacks the human race, though he will not shun man when he meets with him. His favourite prey appears to be the larger quadrupeds, such as oxen, horses, deer, and dogs, which he attacks indiscriminately, and in the same treacherous manner as the rest of his tribe, uniformly singling out the last of a herd as the object of attack. When he has made choice of a victim, he springs on its back, and, placing one of his paws upon the back of the head, whilst he seizes to mangle with the other, twists its head round with a sudden jerk, thus dislocating its spine, and instantly depriving it of life. The jaguar is generally considered as untameable, and to maintain his savage ferocity even in the captive state; but this assertion is amply contradicted by facts. The inhabitants of South America hunt the jaguar in various ways, either with a pack of dogs or by means of the hunter; this latter mode, however, can only be employed upon plains or open grounds. The Indians are not hardy enough to attack this formidable creature single handed, armed with a lance of five feet in length, and their left arm enveloped in a sheep skin; by means of which, they frustrate the first onset of the furious animal, and gain sufficient time to plunge their weapon into his body, before he has time for a second attack. Notwithstanding the strength and ferocity of the jaguar, he is not a powerful opponent in the great ant-eater, although this latter animal has no teeth to defend himself; it

soon as the jaguar attacks the ant-eater, it lies down on its back, and suffocates or strangles him with its long claws.

**JAHN, FREDERIC LOUIS**; inventor of the modern system of gymnastics, born in 1778, in Pomerania, in the village of Lams, near Lensen. His father was a clergyman. He studied in Jena, Halle, and Griefswalde, and exerted himself much to suppress the *Landmanschaften* (combinations of the students, according to the sections of the country to which they belonged), which excited so much sectional feeling among them. (For an account of these *Landmanschaften*, see *Universities*.) In 1809, he went to Berlin, and became an instructor in a private institution. At that time, the French were masters of Germany, and the best means of preparing the Germans for a contest with their oppressors constantly employed the mind of Jahn and others of his countrymen. With the view of exciting patriotic feeling among the young men of Germany, he established, in 1811, his first gymnasium. No conversation was permitted in French, or in any language but their own; national songs were sung. Gymnastic exercises had long before been introduced into Schrepfenthal, by Gutsmuths; but Jahn first conceived the idea of making gymnasia national establishments for education. (See *Gymnastics*.) During the war which soon after broke out between Germany and France, the gymnasia were suspended; but when peace was concluded, in 1814, Jahn reopened his institutions, and exerted all his powers again to make them schools of patriotism. In the mean time, the liberal spirit which spread over the continent of Europe, found its way into the gymnasia. The German governments began to dread the effects of that love of freedom in the nation, which they had themselves used for the overthrow of the French. After the murder of Kotzebue, by the student Sand, the governments fearing, or professing to fear, the existence of secret combinations of a political character in the gymnasia, Jahn and many of his friends were arrested, and treated in a very arbitrary and illegal manner. In 1825, the tribunal at Frankfurt declared Jahn to be innocent. Several of his scholars were also imprisoned, and, after long confinement, liberated without trial.

**JAHN, JOHN**, born at Taswitz, in Moravia, in 1750, professor of theology in the university of Vienna, died in August, 1816. Jahn published, among other works, a Chaldaic and Syriac Grammar (Vienna, 1793); Arabian Grammar (1796); Biblical Archeology (2 vols., ib., 1797 to 1800; 2d edit., ib., 1817 to 1818, part of which has been translated into English, under the title of the Hebrew Commonwealth, (Andover, 1828); *Elementarbuch der Hebräischen Sprache* (2 vols., 1799); *Arabische Chrestomathie* (1802); *Introductio in Libros Sacros Veteris Fœderis* (ib., 1804; 3d edit., ib., 1825); *Archæologia Biblica*, an abridgment, in Latin, of the larger work on Biblical Archeology in German (Vienna, 1804; 2d edit., Vienna, 1814), translated into English (Andover, 1st edit., 1823; 2d edit., 1827); *Grammatica Hebraica* (ib., 1809); *Vaticinia Prophetarum, Commentarius criticus in Libros Prophetarum Vet. Testamenti*. (ib. 1815); Appendix to his theological works (1821).

**JAIL, or GAOL**; a prison or place of legal confinement. This word is formed from the French word *geole*, and that from the barbarous Latin word *gola*, *gaola*, *gayola* (a cage); whence the Picards still call a bird-cage *gayolle*. For some remarks on the subject of prisons, see *Prison*.

**JALAP**, has received its name from being principally brought from the environs of Xalapa; though the plant which produces it is abundant in

other parts of Mexico, even in the immediate vicinity of Vera Cruz. It is much employed in medicine, as a very valuable purgative, and has been known in Europe since the year 1610. It is exported exclusively from Vera Cruz, to the amount of about 400,000 pounds annually. The plant is the *convolvulus jalapa* of authors, an herbaceous twining vine, having entire cordate or three to five lobed leaves, and large white flowers with purple veins. The root, which is the part employed, is very large, sometimes weighing fifty pounds.

**JAMAICA**; (from *Xaymaca*, the name given it by the aborigines), one of the West India islands, belonging to Great Britain, and the most considerable and valuable of her possessions in that quarter. It is of an oval form, about one hundred and fifty miles in length, and, on a medium, about forty miles in breadth; lying thirty leagues west of St Domingo. Long. 76° 45' W. lat. 18° 12' N. A lofty range of mountains, called the Blue mountains, runs through the whole island from east to west, dividing it into two parts, and rising in some of its most elevated peaks to 7431 feet above the level of the sea. On the north and south sides of these mountains, the aspect of the country is extremely different. On the north side of the island, the land rises from the shore into hills, which are more remarkable for beauty than boldness, being all of gentle acclivity, and commonly separated from each other by spacious vales and romantic inequalities. Every valley has its rivulet, and every hill its cascade. On the southern side of the island, the scenery is of a different nature, consisting of the stupendous ridges of the Blue mountains, of abrupt precipices and inaccessible cliffs, approaching the shore. The soil of Jamaica is in some places deep and fertile; but, on the whole, Edwards pronounces it to be an unfruitful and laborious country, compared with those which have been generally regarded as fertile. He calculates the island to contain 4,080,000 acres, of which not more than about 2,000,000 have been granted to individuals by patent from the crown. The island is well watered. There are about 100 rivers, which take their rise in the mountains, and run, commonly with great rapidity, to the sea on both sides of the island. None of them are navigable except for boats. Black river is the deepest, and has the greatest current. There are springs, both sulphureous and chalybeate, in different parts of the country. The climate of Jamaica on the plains is hot, the average heat from June to November inclusive, being 80° Fahr., and, in the colder season, from 70 to 80. On the higher grounds the heat is less. The year, as in all tropical countries, may be divided between the wet and dry seasons. Sugar, indigo, cotton, and coffee are the most important natural productions of Jamaica. Maize, or Indian, and Guinea corn, and rice, are also cultivated. The bread-fruit tree, with several other useful plants, has been introduced by the exertions of Sir Joseph Banks. The island also abounds with different kinds of grass, of excellent quality. The several kinds of kitchen garden produce, namely those edible roots and pulse which are in use throughout Europe, thrive well in the mountainous parts. There are also excellent vegetables of native growth. The other indigenous productions are plantains, bananas, yams of several varieties, calaloe (a species of spinage), eddoes, cassavi, and sweet potatoes. Fruits are found in equal perfection and variety, and no country affords so magnificent a dessert. The mountains are also covered with extensive woods, containing excellent timbers, some of which are of prodigious growth and solidity; while others, as the well known mahogany, are well adapted for cabinet work. The indigenous quadrupeds of the island were the agouti, the pecare or

Mexican hog, the armadillo, the opossum, the raccoon, the musk-rat, the alco, and the monkey. The agouti perhaps remains, and the raccoon was numerous in the time of Sir Hans Sloane. The other animals are extirpated. Of the lizard, there are many varieties. The woods and marshes abound in great variety of wild fowl, some of excellent flavour. Parrots are still found in the groves; but the flamingo is nowhere to be seen. The limit of the miasmata and pestilential atmosphere, in this zone, is supposed to be at an elevation of about 1300 feet above the sea. At that height, the air is perfectly salubrious. The high district, called *Pedro plains*, on the south-west coast of Jamaica, is said, by Bryan Edwards, to vie with any spot on the surface of the globe, in the mildness of its temperature and the purity of its air. At the estate of Cold Spring, 4200 feet above the level of the sea, he thought the climate the most delightful he had ever experienced; the thermometer seldom falls below 56°, or exceeds 70°; and many English fruits, as the apple, peach, strawberry, &c., flourish there in perfection.

Jamaica is situated near the limits of the great volcanic region of South America, and it is, in consequence, liable to earthquakes. June 7, 1802, at mid-day, an earthquake destroyed the town of Port Royal. The convulsion lasted about three minutes, when the town sank several fathoms under water. The walls of the buildings may still be seen in calm weather. The heavy buildings throughout the island were thrown down, shattered mountains ruined many settlements, general sickness ensued, order and industry were at an end, and a mischievous confusion prevailed until the terror subsided; 3000 lives were lost by this visitation. Smart shocks are felt almost every year; in 1802, and again in 1816, they were more violent than usual. Hurricanes are more frequent, and in many cases, more terrible and destructive than earthquakes. A succession of hurricanes desolated this and some of the neighbouring islands for seven years, beginning in 1780, with the exception only of 1782 and 1783. The first, in 1780, was much the most destructive. The amount of property destroyed exceeded 2,000,000 pounds sterling.

The grazing farms have lately increased much, and horned cattle are abundant. They feed on Guinea grass, which was introduced by means of seeds brought and dropped by birds, in the middle of the last century. The oxen are chiefly from the Spanish breed, small, but hardy. The sheep are said to have been originally African. The swine are smaller than those of Europe, and have short pointed ears. The pork is said to be much whiter and sweeter than that of Great Britain. The wild hog abounds in the remote woods. The chase of the wild boar is a favourite diversion of the Creole whites. The Creole horses are small, but active. The British and North American horses do not so well endure the climate. The mules do the heavy work of the plantations, and are capable of enduring twice as much fatigue as a horse. The latter is seldom used as a beast of burden. The carts and wagons are drawn by oxen. The rats are very numerous and destructive, particularly to the sugar cane; in some years, whole fields of this plant are as completely destroyed by them as if a blight had alighted on them. Eight or ten hog-heads of sugar are supposed to be annually lost in this way out of every hundred. 50,000 rats have been caught on some properties in a single year, but no sensible diminution of their number takes place. The negroes eat them dressed in molasses.

The legislature of Jamaica is composed of the governor, of a council nominated by the crown, consisting of twelve gentlemen, and a house of assembly containing forty-three members, who are elected by

the freeholders. The most important articles of export produced in the island are sugar, rum, molasses, coffee, cocoa, cotton, indigo, pimento, and ginger. Of these were exported in the year 1828, as follows:—Sugar, 86,386 hhds; Rum, 34,668 punches; Coffee, 16,530,751 lbs.; Pimento, 2,872,166 casks and bags; Ginger, 2,344 casks. The annual public revenue of Jamaica is about £300,000, and the local taxation nearly a similar sum. In 1830, the total shipping inwards was, number, 715; tons, 130,721; outwards, number, 680; tons, 130,747. Population of Jamaica at different periods:—

Years.	Whites.	Free People of Colour.	Slaves.
1658 . . . .	4,500 . . . .	— . . . .	1,400 . . . .
1787 . . . .	30,000 . . . .	10,000 . . . .	250,000 . . . .

The slaves amounted in 1812, to 319,912; in 1817, to 346,150; in 1826, 331,119. By returns made in 1833, the slaves were numbered at 302,632. Thus, by the emancipation bill, ceased from the 1st of August, 1834, to be slaves, and became apprenticed labourers. The whites in the same year were estimated at 85,000, and the maroons at 1200. The military establishment of the island generally consists of about 3000 regulars, and from 16 to 18,000 militia. The capital of Jamaica is St Jago de la Vega, or Spanish Town (7000 inhabitants). Kingston is the principal place in the island (35,000 inhabitants).

*Historical Sketch.*—Jamaica was discovered by Columbus, May 3, 1494, in his second expedition to the new world. In June, 1503, being on his return from Veragua to Hispaniola, he was driven by tempestuous weather upon this island, where he remained upwards of twelve months, having lost his vessel, and suffered every variety of hardship. After his death, his son Diego, as hereditary viceroy of the countries discovered by his father, sent out, in 1508, to Jamaica, Juan de Esquivel, who conciliated the natives by his kindness; and the island prospered under his administration. His successors, however, appear to have adopted the cruel policy of other governors of that period. So entire was the extermination of the Indians at Jamaica, that of a population of 60,000 persons living at the discovery of Columbus, not a single descendant was alive less than a century and a half afterwards. In 1494, an English party took the capital, and delivered it up to pillage. Forty years afterwards, it was again invaded by a force from the Windward islands, and the town of St Jago de la Vega was plundered. Jamaica was finally conquered by the English during the administration of Oliver Cromwell. The whole number of whites at this time did not exceed 1200, and the number of negroes was about the same. The Spanish inhabitants, rendered desperate by oppression, made a manly resistance, and for a long time the British were harassed by their vindictive incursions. Cromwell encouraged emigration, both from Great Britain and the other colonies in the West Indies. Two or three thousand persons were engaged by Henry Cromwell in Ireland, and a considerable number embarked from Scotland for this purpose, and, in the hands of governor D'Oyley, the government, was administered with energy. In May, 1664, an attempt was made by the Spaniards to recover the island; but the force which landed for this purpose was repulsed. About this time, the settlement became the resort of the buccanniers, who spent their immense gains in characteristic extravagance, and enriched the inhabitants. After the restoration of Charles II., Jamaica became a place of refuge for many republicans who had distinguished themselves in the civil contest. One of the first measures of the monarch was to continue D'Oyley in office, and authorise the election of a council and assembly of

representatives by the people. This, which was the establishment of a regular civil government, the island having been previously governed by martial law, took place in 1661. Afterwards, controversies arose between the assembly and the crown, which unsettled the affairs of Jamaica for a space of fifty years. At length, in 1728, a compromise was effected. The assembly consented to settle on the crown a standing revenue of £8000 per annum, on certain conditions, of which the following are the principal:—1. That the quit rents arising within the island should form part of the revenue; 2. that the body of their laws should receive the royal assent; and, 3. that all such laws and statutes of England, as had been esteemed laws in the island, should continue such. The most important event in the recent history of Jamaica, is the final overthrow and exile of that formidable band of fugitive negroes, who, under the name of *Maroons*, had formed an independent and hostile community in the island, for the greater part of a century. On the conquest of the island from the Spaniards, a multitude of African slaves fled to the mountains, beyond the reach of the invaders, and maintained themselves in these fastnesses in spite of all their efforts. Their numbers were continually increased by the accession of deserting slaves, and a harassing conflict was kept up with the whites, in which the latter were the principal sufferers. In 1738, an accommodation was effected, and a species of independence guaranteed to these hardy outlaws; but at length, in 1795, hostilities broke out again. The activity and skill of the Maroons rendered them an overmatch for the great force brought against them. In this state of things, the British resorted to the use of blood-hounds, 100 of which were imported from Cuba, and, under the direction of experienced huntsmen, were let loose upon the mountaineers, to seize and tear the unhappy fugitives. Thus hunted down like wild beasts, and hemmed in by a force too powerful to be overcome, they had no alternative but submission. The expulsion of this brave and unhappy race was determined upon, and finally carried into effect. About six hundred were transported to the cold and bleak shores of Nova Scotia, where many of them perished miserably. See *Long's Hist. of Jamaica* (3 vols., 1774); *Edwards's Hist. of the W. Indies* (1809); *Roughley's Jamaica Planter's Guide* (1820).

JAMBLICHUS; an eminent philosopher, a native of Chalcis, in Cælosyria, who flourished in the beginning of the fourth century. He was the scholar of Anaximandus and of Porphyry, and having become perfect in the mysteries of the Plotinian school, he taught with vast reputation. He professed to perform wonders by the aid of invisible beings. His writings discover extensive reading, but his style is inelegant, and he borrows freely, especially from Porphyry. The school of Jamblichus produced many eclectic philosophers, who were dispersed throughout the Roman empire. The philosophical works of Jamblichus, now extant, are, the *Life of Pythagoras*; an *Exhortation to the Study of Philosophy*; *Three Books on Mathematical Learning*; a *Commentary upon Nicomachus's Institutes of Arithmetic*; and a *Treatise on the Mysteries of the Egyptians, Chaldeans and Assyrians*. St Jerome states that he also wrote a copious commentary on the golden verses of Pythagoras. He died about 333. This Jamblichus must be distinguished from the person of the same name, to whom the emperor Julian dedicates his epistles, for Julian was scarcely born when the successor of Porphyry died. The best editions of Jamblichus are these: *De Myst. Egypt. Chald. et Assy.* *secundum alii Tractatus philosophici*, Aldus (Venice, 1497); *De Myst. Egypt. necnon Porphyrii Epistola,*

*&c., Gr. et Lat.*, Gale (Oxon. 1678); and *De Vita Pythag., Gr. et Lat.*, Kuster (Amsterdam, 1704, 4to).

JAMES, St, called the *Greater*, the son of Zebedee and the brother of John the evangelist, was born at Bethsaida in Galilee. He was called to be an apostle, together with St John, as they were mending their nets with their father Zebedee, who was a fisherman. Christ gave them the name of *Boanerges, or sons of thunder*. They then followed Christ, were witnesses with St Peter of the transfiguration on mount Tabor, and accompanied our Lord in the garden of Olives. It is believed that St James first preached the gospel to the dispersed Jews, and afterwards returned to Judea, where he preached at Jerusalem, when the Jews stirred up Herod Agrippa against him, who put him to a cruel death, about the year 44. Thus St James was the first of the apostles who suffered martyrdom. St Clement of Alexandria relates that his accuser was so struck with his constancy, that he became converted, and suffered with him. There is a magnificent church at Jerusalem, which bears the name of St James, and belongs to the Armenians. The Spaniards pretend that they had St James for their apostle, and boast of possessing his body; but, Baronius, in his annals, refutes their pretensions.

*James, St*, called the *Less*, an apostle, the brother of Jude, and the son of Cleophas and Mary, the sister of the mother of our Lord, is called in Scripture the *Just*, and the *brother of Jesus*, who appeared to him in particular after his resurrection. He was the first bishop of Jerusalem when Ananias II., high priest of the Jews, caused him to be condemned and delivered into the hands of the people and the Pharisees, who threw him down from the steps of the temple, when a fuller dashed out his brains with a club, about the year 62. He was the author of the epistle which bears his name.

JAMES, St, OF THE SWORD (*San Jago del Espada*); a military order in Spain, instituted in 1170, by Ferdinand II., king of Leon, to stop the incursions of the Moors. The knights must prove their descent from families that have been noble on both sides for four generations, and that their ancestors have neither been Jews, Saracens, nor heretics, nor called in question by the inquisition. Their vows are those of poverty, obedience, conjugal fidelity, and the defence of the immaculate conception of the holy virgin.

JAMES I., king of Scotland, of the house of Stuart, born in 1394, was the son of Robert III., by Annabella Drummond. In 1405, his father sent him to France in order that he might escape the danger to which he was exposed by the ambition of his uncle, the duke of Albany; but being taken by an English squadron, he and his suite were carried prisoners to the Tower of London. Here he received an excellent education from Henry IV. of England; and, to relieve the tedium of captivity, applied himself to those poetical and literary pursuits, the existing evidence of which do him honour. Robert III. died the following year, and James was proclaimed king; but, during the remainder of the reign of Henry IV., and the whole of that of Henry V., he was ungenerously detained in England, with a view to prevent the alliance of Scotland with France. This did not, however, prevent the apprehended result. At length, under the regency of the duke of Bedford, he was restored to his kingdom, after a detention of eighteen years, at which time he was in his thirtieth year, and highly accomplished, both mentally and in the manly exercises. He married Joanna Beaufort, a lady of distinguished beauty, of the blood royal of England, who is thought to be the fair dame

alluded to in his pleasing poem of the King's Quhair, of whom he became enamoured, from beholding her in the royal gardens from the windows of his apartments, while a captive in Windsor castle. On his return to Scotland, finding that the duke of Albany and his son had alienated many of the most valuable possessions of the crown, he caused them to be convicted and executed as traitors, and their estates to be confiscated. These and some other strong measures in the resumption of improvident grants, under the regency of the dukes of Albany, were atoned for by the enactment of many good laws in his parliaments; and, as far as a lawless nobility would allow them to be put in practice, they much improved the state of society in Scotland. In 1436, he renewed the Scottish alliance with France, giving his daughter Margaret in marriage to the dauphin, and sending with her a splendid train, and a large body of troops. A fruitless endeavour of the English to prevent this marriage, by intercepting the Scottish fleet in its passage, so exasperated James, that he declared war against England. He was, however, on such bad terms with his nobility, in consequence of his endeavours to curb their ambition and improve his revenue, that he was obliged to disband his army, under the apprehension of a conspiracy. He then retired to the Carthusian monastery of Perth, which he had himself founded, where he lived in a state of privacy, which facilitated the success of a plot formed against his life. The chief actors in this tragedy were Robert Graham, and Walter, earl of Athol, the king's uncle, the former of whom was actuated by revenge for the resumption of some lands improperly granted to his family, and the latter by the hopes of succeeding to the crown. By means of bribery, the assassins gained admission to the king's apartment; and an alarm being raised, the queen's ladies attempted to secure the chamber door. One of them, Catharine Douglas, thrust her arm through the staple, in which state she remained until it was dreadfully broken by the assailants. The instant the assassins got into the apartments, they dragged the king from his concealment, and, in spite of the cries and remonstrances of the queen, who in vain threw herself between them and the object of their resentment, put him to death by multiplied wounds. He perished in the forty-fourth year of his age, and thirteenth of his reign, Feb. 20, 1437, leaving one son and five daughters; and his murder was punished by the deaths of the conspirators in exquisite tortures. The king, who may be said to have fallen a martyr to his attempts to abolish the anarchy and disorder which prevailed throughout his kingdom, holds no inconsiderable place in the catalogue of royal authors; by his poem of the King's Quhair. James is also said to have been a skilful musician, and some attribute to him the composition of several of the most admired of the Scottish melodies; but of this Doctor Burney is much inclined to doubt. An ascribed list of the works to James I. will be found in Park's edition of Walpole's Royal and Noble Authors. Among these are three admirably descriptive poems, respectively entitled, "Christ's Kirk on the Green," "Pebbles to the Play," and "The Gaberlunzie Man," the authorship of which is sometimes given to James I., and sometimes to James V., but in neither case with much probability. All that can be said with any degree of certainty is, that James V. from his well-known roving propensities, was in all likelihood the *Aero* of the last mentioned piece.

JAMES V. of Scotland succeeded, in 1513, at the death of his father, James IV., though only eighteen months old. His mother, Margaret of England, governed during his childhood; but, at the age of seventeen, he assumed the reins of government, and,

in 1535, married Magdalen, daughter of Francis I., who died two years after. He afterwards married Mary of Lorraine, widow of Louis of Orleans, and died Dec. 13, 1542, leaving the throne to his only child, Mary Stuart, who was born only eight days before his death.

JAMES VI. of Scotland, and I. of England, was the son of Mary, queen of Scotland, by her cousin Henry lord Darnley. He was born at Edinburgh castle, in June, 1566, at the unfortunate period when his mother was at variance with her husband, and had begun to fix her affection on the earl of Bothwell. In the stormy and disgraceful times which followed, the infant prince was committed to the charge of the earl of Mar; and, in the following year, Mary being forced to resign the crown, he was solemnly crowned at Stirling, and from that time all public acts ran in his name. His childhood was passed in civil wars, under the regencies of Murray, Mar and Morton, during which time he resided in Stirling castle, under the tuition of the celebrated Buchanan. His progress in school-learning was rapid; but, as his character opened, an instability and weakness of temper became manifest, which indicated what, in the sequel, proved to be the case, that he would become an easy prey to flatterers, and his reign be marked by injudicious favouritism. From the first, too, he seems to have imbibed those exalted notions of the royal authority and divine right which proved so injurious to his posterity. Some injudicious measures, in the spirit of these opinions, early produced a conspiracy of his nobles against him, who, in 1568, took possession of his person at Ruthven castle. A new confederacy, however, effected his liberation, and he again put himself under the direction of his favourite, the earl of Arran. The policy of queen Elizabeth, whose apprehensions from the Catholic party in favour of Mary, led her to employ every art to keep up a dissatisfied party in Scotland, was greatly assisted by the violent and unprincipled measures of Arran against the connexions of the late complexion, many of whom fled to England. When, however, it became apparent that the life of his mother was in danger from the sentence of an English judgment, James, who had hitherto treated her very inconsiderately, felt himself called upon to interfere. He accordingly wrote a menacing letter to Elizabeth on the subject, appealed to other courts for assistance, and assembled his nobles, who promised to assist him either to prevent or revenge that queen's injustice. When the news of the catastrophe arrived, he adjusted with proper spirit the excuses of Elizabeth, and prepared for hostilities; but he was finally prevented from engaging in actual war by the inadequacy of his resources. One of the first acts of his majority was to reconcile the feuds of his nobility, whom, for that purpose, he invited to a grand festival at Holmhouse. On the threatened invasion of England by Philip II. he judiciously resolved to assist Elizabeth against the Spaniards, and was zealously supported by his people for the preservation of Protestantism, who entered into a national covenant to maintain it. In 1589, James married Anne, daughter of Frederick, king of Denmark. On his return home, after passing the winter in festivities at Copenhagen, he was in some danger from conspiracies against his life; and, for several succeeding years of his reign, the history of Scotland displays much turbulence and party contest. In 1600, while the country was in a state of unusual tranquillity, a very extraordinary event took place, the causes of which were never discovered. While the king was upon a hunting excursion, he was invited by the brother of Ruthven, earl of Gowrie, to ride with a small train to the earl's house at Perth. Here he was led to a remote chamber, on pretence of

secret to be communicated to him, where he found a man in complete armour; and a dagger was put to his breast by Ruthven, with threats of immediate death. His attendants, being alarmed, came to his aid. Gowrie and his brother were slain, and the king escaped unhurt. In 1603, James succeeded to the crown of England, on the death of Elizabeth, and proceeded, amidst the acclamations of his new subjects, to London. One of his first acts was to bestow a profusion of honours and titles on the inhabitants of both countries, in which, as in many other points, he displayed a contrast to the maxims of the late reign. A conference held at Hampton court, between the divines of the established church and the Puritans, afforded James an opportunity of exhibiting his skill in theological controversy, and the ill will he bore to popular schemes of church government. The meeting of parliament also enabled him to assert those principles of absolute power in the crown which he could never practically maintain, but the theoretical claim of which provided the increasing spirit of freedom in the house of commons with constant matter of alarm and contention. Although James had behaved with great lenity to the Catholics in Scotland, those in England were so disappointed in their expectations of favour, that the famous gunpowder plot was concerted in 1605, the object of which was to blow up the king and parliament. (See *Gunpowder Plot*.) His cares for reducing and improving Ireland do him honour. In 1612, he lost his eldest son, Henry, a prince of great promise, then of the age of nineteen; and, in the following year, the eventful marriage of his daughter Elizabeth with the elector palatine took place. About this time, the object of the weak passion of James for handsome favourites was Robert Carr, a youth from Scotland, who in a short time was raised from a court page to be earl of Somerset, and was loaded with honours and riches. The scandalous murder of Sir Thomas Overbury, by the machinations of this minion and his infamous countess, put an end to the king's partiality, although he disgracefully pardoned the principals in the murder, while he allowed their agents to be executed. The fate of Somerset paved the way for the rise of George Villiers, duke of Buckingham. (See *Buckingham*.) No circumstance in the reign of James was more unpopular than his treatment of the celebrated Sir Walter Raleigh. Soon after the king's accession, that statesman, who had been opposed to the Scottish succession, engaged in a plot to set aside James in favour of the lady Arabella Stuart, for which he was tried and capitally convicted, but, being reprieved, was kept thirteen years in prison. In 1615, he obtained his release by dint of money, and was allowed to set out upon an expedition to the South seas, in search of gold, with the sentence of death hanging over his head. He was unsuccessful in his objects, and James, instigated, as it is supposed, by his desire of an alliance between prince Charles and the Infanta of Spain, listened to the suggestions of the latter power, and, to the great scandal of the whole nation, Sir Walter was executed upon his former sentence. The match with the Infanta, notwithstanding, failed, and Charles married Henrietta Maria, daughter of Henry IV. of France, with the disgraceful stipulation, that the children should be brought up by their mother until thirteen years of age; to which arrangement the future religious opinions of Charles II. and James II. may, perhaps, be attributed. The close of the life of James was marked by violent contests with his parliament, which prepared dreadful consequences for his successor. He was also much disquieted by the misfortune of his son-in-law, the elector palatine, who, having been induced to accept the crown of Bohemia, and to head the Protestant

interest in Germany, was stripped of all his dominions by the emperor. Urged by national feelings for the Protestant cause, he was at length, in 1624, induced to declare war against Spain and the emperor; and troops were sent over to Holland to act in conjunction with prince Maurice. The defeat of this enterprise, through sickness and mismanagement, it is thought, produced the king so much uneasiness as to cause the intermittent fever by which he was soon after attacked, and of which he died in March, 1625, in the fifty-ninth year of his age.

James was not destitute of abilities, nor of good intentions, but the former were not those of a ruler, and the latter were defeated by pliability and unmanly attachments. His reign, although not unprosperous to his subjects, was inglorious in character and loss of influence, and he was neither beloved at home nor esteemed abroad. He received during his lifetime a great deal of adulation, on the score of his literary abilities; but he merits far more as an encourager of learning, than for the fruits of it displayed by himself, all of which were debased by pedantry and prejudice. Upon the whole, the good qualities of James were unstatesmanlike, and his bad ones unmanly and puerile.

JAMES VII., king of Scotland, and II. of England, second son of Charles I. and of Henrietta of France, was born in October, 1633, and immediately declared duke of York. After the capture of Oxford by the parliamentary army, he escaped, in 1648, at the age of fifteen, and was conducted to his sister, the princess of Orange. He soon after joined his mother at Paris, and, when he had reached his twentieth year, served in the French army under Turenne, and subsequently entered the Spanish army in Flanders, under don John of Austria and the prince of Condé. In these campaigns he obtained reputation and experience, although with the display of no very great or shining qualities. At the restoration, he took the command of the fleet, as lord high admiral. He had previously married Anne, daughter of chancellor Hyde, afterwards lord Clarendon (see *Clarendon*), and ungenerously attempted to free himself from the union; but the marriage being satisfactorily established, he could not succeed. In 1664, he took a leading part in promoting a Dutch war, for the alleged interests of trade, and, June 3, 1665, with a powerful fleet under his command, engaged that of the Dutch under Opdam, who, with his ship, was blown up in the action, and nineteen of his squadron were sunk or taken, with the loss of only one on the part of the English. In 1671, the duchess of York died, leaving her husband two daughters, who became successively queens of England. Before her death, she declared herself a convert to the Roman Catholic faith, which had been secretly that of the duke for many years, and was now openly avowed by him. This declaration produced a great impression on the people, and laid the foundation of the opposition which finally drove him from the throne. In the Dutch war of 1672, he was again placed at the head of the fleet, and, being attacked by De Ruyter, a furious engagement ensued. The Dutch fleet at length retired. A test act being soon after passed, to prevent Roman Catholics from holding public employments, the duke was obliged to resign his command—a result which induced him to join heartily in the plot of the king and certain of his counsellors, to restore the Roman Catholic religion. In 1671, he married Mary Beatrice of Este, daughter of the duke of Modena, and, in 1677, his eldest daughter, Mary, was united to William, prince of Orange. During the violent proceedings on account of the supposed popish plot in 1679, by the advice of the king, he retired to Brussels, and a bill passed the commons for his exclu-

sion from the throne, which was, however, rejected by the lords. When the royal party again prevailed, the duke, in 1681, was sent into Scotland, where he acted with great rigour, not to say cruelty, to the remnant of the Covenanters. It is even said that he sometimes personally assisted at the torture of criminals, and altogether exhibited himself as a man of a severe and unrelenting temper. During the whole of the remaining reign of Charles II., indeed, during which he possessed great influence in the government, he was forward in promoting all the severe measures that disgraced it.

On the death of Charles II., in February, 1685, the duke succeeded, under the title of James II., and, from the time of his ascending the throne, seems to have acted with a steady determination to render himself absolute, and to restore the Roman Catholic religion. After disgusting the great majority of his subjects, by attending mass with all the ensigns of his dignity, he proceeded to levy the customs and excise without the authority of parliament. He even sent an agent to Rome, to pave the way for a solemn re-admission of England into the bosom of that church, and received advice, on the score of moderation, from the pope himself. This conduct encouraged the rebellion of the duke of Monmouth. The unrelenting temper of James was again exhibited in the executions on this account. The legal proceedings under Jeffreys were brutal in the extreme; and it is estimated that no fewer than 251 persons suffered in the west of England by the cruel proceedings of that infamous judge, which it was the custom of the king to gibe upon, under the name of *Jeffreys' campaign*. The temporary awe, produced by this severity, even in parliament, was so great, that James was encouraged to throw off almost all disguise, both in regard to religion and government. By virtue of his assumed disposing power, he rendered tests of no avail, and filled his army and council with Roman Catholics. He put Ireland entirely into their hands, and governed Scotland by a few noblemen who had become converts to the same faith. He gradually proceeded to a direct attack on the established church, by the formation of an ecclesiastical commission, which cited before it all clergymen who had done any thing to displease the court. A declaration of indulgence in matters of religion, was ordered to be read by the clergy in all the churches of the kingdom. Seven bishops met, and drew up a loyal and humble petition against this ordinance, which step being considered as an act of disloyalty, they were sent to the tower. The innovations, in regard both to the religion and government, gradually united opposing interests, and a large body of nobility and gentry concurred in an application to the prince of Orange, who had been secretly preparing a fleet and an army for the invasion of the country. James, who was long kept in ignorance of these transactions, when informed of them by his minister at the Hague, was struck with terror equal to his former infatuation; and, immediately repealing all his obnoxious acts, he practised every method to gain popularity. All confidence was, however, destroyed between the king and the people. William arrived with his fleet in Torbay, November 4, 1688, and landed his forces; but the remembrance of Monmouth's rebellion, for some time, prevented the people in the west from joining him, until, at length, several men of rank went over, and the royal army began to desert by entire regiments. Incapable of any vigorous resolution, and finding his overtures of accommodation disregarded, he resolved to quit the country. He repaired to St Germain, where he was received with great kindness and hospitality by Louis XIV. In the mean time, the throne

of Great Britain was declared abdicated, and was filled, with the national and parliamentary consent, with his eldest daughter, Mary, and her husband, William, conjointly; Anne, who had equally with her sister, been educated a strict Protestant, being declared next in succession, to the exclusion of the infant prince. Assisted by Louis XIV., James was enabled, in March, 1689, to make an attempt for the recovery of Ireland. The battle of the Boyne, fought July, 1690, compelled him to return to France. All succeeding projects for his restoration proved equally abortive, and he spent the last years of his life in acts of ascetic devotion. He is said to have entered into the society of Jansen. He died at St Germain, September 16, 1701, at the age of sixty-eight.

JAMES III., the Pretender. See *Stuart, James Edward Francis*.

JAMES, ROBERT, an ingenious physician and medical writer, but best known as the inventor of a specific for the cure of fever, was born in 1708. He practised medicine in London, and engaged in the compilation of a medical dictionary, which appeared in 1743, in three volumes, folio. In this work James is said to have been assisted by his friend Dr Johnson, who has warmly eulogized his professional services in his *Lives of the Poets*. He published, in 1751, a Dissertation upon Fevers, the purpose of which was to recommend a peculiar medicine, since known by the name of *James's powder*. For this preparation he procured a patent, and sold it as a secret remedy by which he exposed himself to the hostility of his professional brethren, who looked upon his conduct as inconsistent with the dignity of the medical character. James's powder is now known to be unmedicated phosphate of lime; and a preparation very similar to it, if not exactly the same, has long held its place in the London Pharmacopœia. The general respectability of his character as a man of sense and literary acquirements, enabled him, in a great degree, to triumph over the prejudices excited by a mode of conduct which placed him so near the law of those pests of society, the majority of advancing empirics and vendors of patent medicines. In 1728, he published a work, entitled the *Practice of Physic* (2 vols., 8vo.), and subsequently a treatise on *consumption*, and a dispensatory. One of his last literary labours was, a *Vindication of the Fever Powder*, as published till after his death, which took place in 1776.

JAMES'S PALACE, Sr, in Pall-Mall, London, a royal palace, stands on the site of an hospital of the same name. It has been the acknowledged residence of the English kings since Whitehall was consumed, in 1696; but, though pleasantly situated on the north side of St James's park, and possessing many elegant and convenient apartments, calculated for state purposes, yet it is an irregular brick building, without a single external beauty to recommend it as a palace. In the front, next to St James's street, little more than an old gate-house appears, which serves as an entrance to a small square court, with a piazza on the west of it, leading to the great staircase. The buildings are low, plain, and mean. Beyond this are two other courts, which have the appearance of a king's palace. The state apartments look towards the park; and this side, though certainly not imposing, cannot be pronounced mean. It is of one story, and has a regular appearance as to be found in other parts of the building. The south-east wing was destroyed by fire in 1806, and has never been rebuilt, though the whole of the palace was repaired in 1821—3. The rooms of the king are magnificent in a high degree. It is from this place that the cabinet of the king of Great

Britain is called the *cabinet of St James's*. Behind this palace is St James's park.

JAMES'S PARK, St., was a complete marsh till the time of Henry VIII., who, having built St James's palace, enclosed it, laid it out in walks, and, collecting the waters, gave the new enclosed ground and building the name of *St James*. It was afterwards much improved by Charles II. He formed the canal, which is 2800 feet long, and 100 broad. Succeeding kings allowed the people the privilege of walking here.

JAMES RIVER; a river, in Virginia, formed by the union of Jackson's and Cowpasture rivers. At the point where it begins to break through the Blue ridge, it is joined by North river. It passes by the flourishing towns of Lynchburg and Richmond, and communicates, through Hampton road and the mouth of the Chesapeake bay, with the Atlantic. Its general course is south of east. A forty-gun ship may go up to Jamestown, and, by lightening herself, to Harrison's bar, where there are fifteen feet of water. Vessels of 250 tons go up to Warwick, and those of 120 to Rockets, just below Richmond. The river is navigable for batteaux 220 miles above Richmond. It opens a navigation into a country abounding in tobacco, wheat, corn, hemp, coal, &c.

JAMESTOWN; a town in James City county, in Virginia, on an island in James river, thirty-two miles above its mouth, eight S. W. Williamsburg, sixty-five E. S. E. Richmond. This town was established in 1606, and was the first town settled by the English in the United States. The town is now in ruins, and almost desolate. Two or three old houses, the ruins of an old steeple, a churchyard, and faint marks of the rude fortifications, are the only memorials of its former importance.

JAMI, or DJAMY (properly *Abd Alrhaman ebn Ahmed*), a celebrated Persian poet, born in 1414, had his surname from his native place *Jam*, in the province of Chorassan. He eclipsed the greatest geniuses of his time. The sultan Abu Said invited him to his court at Herat; but Jami, who was a follower of the doctrine of the Sophi, preferred the ecstasies of a mystic to the pleasures of the court. He often sat in the hall of the great mosque at Herat, where he conversed in a free and friendly manner with the common people, instructed them in the principles of virtue and religious faith, and won their hearts by his gentle and persuasive eloquence. When he died, in 1494, the whole city was in sorrow. The sultan gave him a magnificent funeral, at the public cost, and the earth, say the Persian poets, opened of itself, like a shell, to receive this invaluable pearl. He was one of the most fruitful of the Persian authors, leaving more than forty works, mostly of a mystical character. Seven of the most interesting he joined together under the title of the Seven Stars of the Bear. To this belongs Jussuf and Zuleika, one of the most entertaining works in Persian, of which Law, in the Asiatic Miscellanies, has published some fragments; also the charming fiction Mejnoun and Leila, which has been translated into French by Chezy, (Paris, 1805), and into German by Hartmann (Leipsic, 1807, 2 vols.) His *Beharistan*, a treatise on morality, in verse and prose, is compared to Sadi's *Ghulistan*. Extracts from it have been printed by Jenisch (in the *Anthologia Persica*) and by Wilken (in the *Arvostomathia Persica*, Leipsic, 1805). According to Goethe, he combines all the excellencies of the earlier Persian poets.

JANEIRO, Rio de. See *Rio de Janeiro*.

JANICULUM (*castellum*), or MONS JANICULUS; one of the seven hills of Rome, on the right bank of the river Tiber, also called *mons Aureus*, on account of the yellow sand (corrupted into *Montorio*).

According to tradition, it received the name of *Janiculum*, because Janus first cultivated it. It afforded the most beautiful view of the city. The *pons Subticius* connected it with the other part of Rome, to which Ancus Martius added it. The hill is now called *Gianicolo*.

JANINA. See *Joannina*.

JANIZARIES. "In the year 1389," says Gibbon, "the Turkish cimiter was wielded by Amurath I., the son of Orchan and the brother of Soliman. He subdued the whole province of Romania or Thrace, from the Hellespont to mount Hæmus and the verge of the capital. He marched against the Sclavonian nations between the Danube and the Adriatic—the Bulgarians, Servians, Bosnians, and Albanians—and their warlike tribes, who had so often insulted the majesty of his empire, were repeatedly broken by his destructive inroads. The natives of the soil have been distinguished in every age by their hardness of mind and body, and they were converted, by a prudent institution, into the firmest and most faithful supporters of Ottoman greatness. The vizier of Amurath reminded his sovereign, that, according to the Mohammedan law, he was entitled to a fifth part of the spoil and the captives, and that the duty might easily be levied if vigilant officers were stationed at Gallipoli to watch the passage, and to select for his use the stoutest and most beautiful of the Christian youth. The advice was followed; the edict was proclaimed; many thousands of the European captives were educated in the Mohammedan religion and arms, and the new militia was consecrated and named by a celebrated dervish. Standing in the front of their ranks, he stretched the sleeve of his gown over the head of the foremost soldier, and his blessing was delivered in these words—'Let them be called Janizaries (*yingi cheri*, or new soldiers); may their countenances be ever bright; their hand victorious; their swords keen; may their spear always hang over the heads of their enemies; and, wheresoever they go, may they return with a white face.' *White and black face* are common and proverbial expressions of praise and reproach in the Turkish language. *Hic niger est, hunc tu, Romane, caveto*, was likewise a Latin sentence. Such was the origin of these haughty troops, the terror of the nations, and sometimes of the sultans themselves."

They were kept up by continual additions from the sultan's share of the captives, and by recruits, raised every five years, from the children of the Christian subjects. Small parties of soldiers, each under a leader, and each provided with a particular firman, went from place to place. Wherever they came, the *protogeros* assembled the inhabitants, with their sons. The leader of the soldiers had the right to take away all the youth who were distinguished by beauty or strength, activity or talent, above the age of seven. He carried them to the court of the grand seignior, a tithe, as it were, of the subjects. The captives taken in war by the pachas, and presented by them to the sultan, included Poles, Bohemians, Russians, Italians, and Germans. These recruits were divided into two classes. Those who composed the one, especially in the earlier periods, were sent to Nolia, where they were trained to agricultural labour, and instructed in the Mussulman faith; or they were retained about the seraglio, where they carried wood and water, and were employed in the gardens, in the boats, or upon the public buildings, always under the direction of an overseer, who with a stick compelled them to work. The others, in whom the traces of a higher character were discernible, were placed in one of the four seraglios of Adrianople or Galata, or the old or new one at Constantinople. Here they were lightly clad in linen or in cloth of Saloniki, with caps of

Prusa cloth. Teachers came every morning, who remained with them until evening, and taught them to read and write. At a particular time, they were all circumcised. Those who had performed hard labour were made janizaries. Those who were educated in the seraglios became either spahis, or higher officers of state. Both classes were kept under a strict discipline. The former, particularly, were accustomed to privation of food, drink, and comfortable clothing, and to hard labour. They were exercised in shooting with the bow and harquebuss by day, and spent the night in a long, lighted hall, with an overseer, who walked up and down, and permitted no one to stir. When they were received into the corps of the janizaries, they were placed in cloister-like barracks, in which the different *odas* or *ortas* lived so entirely in common, that the military dignities were called from their soups and kitchens. Here not only the younger continued to obey the elders in silence and submission, but all were governed with such strictness, that no one was permitted to spend the night abroad, and whoever was punished was compelled to kiss the hand of him who inflicted the punishment. The younger portion in the seraglios were kept not less strictly, every ten being committed to the care of an inexorable eunuch. They were employed in similar exercises, but likewise in study. The grand seignior permitted them to leave the seraglio every three years. Those who chose to remain, ascended, according to their age, in the immediate service of their master, from chamber to chamber, and to constantly greater pay, till they attained, perhaps, to one of the four great posts of the innermost chamber, from which the way to the dignity of a beglerbeg, of a capitan deiri (that is, an admiral), or even of a visier, was open. Those, on the contrary, who took advantage of this permission, entered, each one according to his previous rank, into the four first corps of the paid spahis, who were in the immediate service of the sultan, and in whom he confided more than in his other body-guards. This institution fully satisfied expectation. An Austrian ambassador at the court of Soliman, Busbequius, whose accounts are to be perfectly relied on, speaks of the strict discipline of these janizaries, which made them appear at one time like monks, and at another like statues, of their simple dress, with only a few heron's feathers for an ornament to their heads, and of their temperate life. They would not suffer one among them, who had grown up in the indulgences of home. This corps has in many instances been the salvation of the empire. The battle of Varna, the foundation of the Ottoman greatness, would not have been gained without them. At Cassova, the Rumanian and Natolian troops had already fled before the *devil*, as they called John Hunniades, yet the janizaries obtained the victory. It was their boast that they had never fled in battle; and Lazarus Suedius, for a long time a German general against them, confessed the truth of this assertion. In all accounts they were called the nerve and the sinew of the Ottoman army. It is worthy of remark, that this invincible infantry of the East was formed about the same time (in 1367) as the not less invincible Swiss infantry. The former, however, was composed of slaves, and the latter of free mountaineers. The whole body was divided into four squadrons, each containing a certain number of *ortas* (troops). Each *orta*, in Constantinople, was supposed to have 100 men; elsewhere, 200 or 300. In time of war, the complement was 500 men. The regimental rolls produced on the pay days made the whole number of the corps 120,000; but those lists were never correct, and they comprehended all in actual service, the supernumeraries who lived by their tracks and callings, and

succeeded in case of vacancies, and the honorary members. Three years' service gave a right to pay in time of peace. As the government furnished only a small allowance of provisions, and clothing for 12,000 men, the privates were suffered to work at their trades. All the men of one regiment were bakers, all those of two others butchers; others, again, were all boatmen, masons, &c., and they were married accordingly. The *kulak*, or cap of dirty white felt, with a long strip hanging down behind, was the distinctive part of a janizary's dress. The Turkish troops were required to find their own arms, but in time of war fire-arms were furnished to all soldiers as had none, from the arsenal at Constantinople. A firelock, pistols, mace, and axe were the arms carried by the infantry; and the janizaries put themselves in having not only well tempered, but also richly ornamented arms. Besides the standards and horse-tails placed before the tent of the aga, or commander-in-chief, each *orta* had its own particular ensign. But a more important distinction, in the estimation of these troops, were the caldrons attached to each *orta*, two or three in number, placed under the care of the subaltern officers. The loss of these was considered as the greatest misfortune which could befall the regiment; and, if they were taken in war, all the officers were immediately cashiered, and in many cases the regiment was publicly disgraced. In these caldrons the broth was carried daily from the barracks to the different guard-houses. The police of the capital and the large towns was intrusted principally to the janizaries. Lampoon and seditious papers affixed to the gates of the mosques, and conflagrations in various parts of the city, were the means by which this formidable body made its displeasure known to the sultan; but the discontent was seldom excited by any thing except the power of some unpopular minister, or the severity of a more rigid discipline. In various instances, sultans were deposed, insulted, and murdered by the insurgent janizaries. This corps offers the only example in Turkish history of a public *sanctimonium* bann. After the dethronement of Osman II., a janizary of the sixty-fifth company dared to raise his hand against his fallen monarch, and strike him in the streets of the city. Amurath III. punished the crime by cutting off the whole company. The memory of the crime and the punishment was renewed twice every month. On Wednesday, when the lights were distributed to the different barracks, the sixty-fifth company was called to receive their portion, but, at the second call, an officer replied, "Let their voice be silent; let them be wholly extinguished." The reforms which were attempted in this corps met with the greatest opposition on the part of the members, and produced several revolutions. It was finally entirely broken up in 1826. In May, 1826, the janizaries had declared themselves willing to have a new militia formed, but on the 14th June of that year, they rebelled on this account; but the sultan and aga Hussein Pacha, at the head of the grand seignior's troops, repulsed the rebels; their barracks were burnt, and many were executed. The proclamation of June 17th abolished the corps for ever, and laid a curse upon the name. The new troops are disciplined in the manner of the Christian nations.

JANSENIUS, CORNELIUS; professor of theology at Louvain, and from 1636 bishop of Ypres in the Netherlands, owes his fame, which eclipses the name of the elder Cornelius Jansenius (bishop of Ghent, died 1571; known as a biblical critic), to the controversy, during his age, concerning the nature and efficacy of divine grace; was born in 1585. devoted principally to the different representations of the doctrine by Augustine, who found it necessary to

express himself differently in his dispute with the Manicheans and in that with the Pelagians, this controversy was revived at the time of the reformation. The vague and contradictory expositions of the papal court on the subject, served only to increase the contention in the Catholic church, where the pride and jealousy of the Dominicans and Augustines on one side, and the artifices of the Franciscans and Jesuits on the other, kept up this angry controversy with increasing warmth, the former contending for the strict anti-Pelagian principles of Augustine, the latter adopting a milder interpretation of them. The latter obtained a triumph over their adversaries, in 1567, by the papal bull condemning seventy-six propositions taken from the writings of the chancellor and inquisitor at Louvain, Michael Baius (died 1589), a learned defender of the Augustine doctrine. But the Spanish Jesuit, Lewis Molina (died 1600), went too far on the other side, in his more than semi-Pelagian commentary on the dogmatics of Thomas Aquinas. The violence of the Molinistic controversies compelled the pope, in 1598, to establish the congregation *de auxiliis* at Rome, for the examination of opinions concerning grace; and, this proving ineffectual to restore harmony, he wisely required (in 1611) of the contending parties, silence on this doctrine.

Jansenius, who was an advocate of the strict Augustine system, which had always prevailed at the university of Louvain, died 1638, at Ypres, with an unblemished reputation for piety and purity of morals. But his *Augustinus*, a book in which he maintained the Augustine doctrine of free grace, and recommended it as the true orthodox belief, in opposition to the semi-Pelagianism of the Molinists, rekindled the controversy on its publication in 1640. The book was condemned by a bull of pope Urban VIII., in 1643; but the partisans of Jansen declared the bull to be spurious; the university of Louvain protested against it; and, even in France, it was ineffectual to suppress the applause with which many distinguished theologians received the *Augustinus*. Jansen's old friend, the abbot of St Cyran, known as the director of the nuns of Port Royal, and a zealous opposer of the Jesuits, as well as for his mysticism and ascetic piety, John du Verger de Hauranne (died 1643), had already prepared the minds of the French theologians for Jansenism. The scholars of the Port Royal, Nicole, Perrault, Pascal (whose Provincial Letters had exposed the old sins of the Jesuits), and, above all, Ant. Arnaud (born 1612; in 1643 made doctor of the Sorbonne), men distinguished no less for religious principles and unblemished virtue than for rare learning and talents, undertook the defence of Jansenism; and the bull, in which the pope (1653) particularly condemned five propositions from the *Augustinus*, met with a strong opposition. The five propositions were these: 1. That there are certain commandments of God which good men are absolutely unable to obey, though they desire to do so, God not having given them a sufficient measure of grace. 2. That no person, in the fallen state of nature, can resist the influence of divine grace. 3. To render themselves meritorious in the sight of God, it is not requisite that men should be exempt from internal necessity, but only from outward constraint. 4. That the semi-Pelagians are heretical in maintaining that the human will is able to resist or obey the influences of divine grace. 5. That to say that Christ died for all men, is semi-Pelagianism.

These propositions are really contained in the book of Jansenius, but his partisans contended that his propositions were not to be understood precisely in this sense, and that the pope was not to be regarded as infallible in determining the meaning

of the writer. Hence arose the important question whether the pope, whose right to decide a point of doctrine had never been disputed, had authority to determine a historical fact. Alexander VII. assumed this in 1656, in a special bull, declaring that Jansenius had understood the propositions in the sense condemned. The Jansenists were thus compelled either to recant or to secede from the Roman church. Although their protest against this unheard-of arrogance of the Romish court, in pretending to know and to determine what a deceased author meant by expressions which admit of a double interpretation, could surprise no impartial person it was yet regarded as an attack upon the infallibility of the pope, and drew down the displeasure of Louis XIV. himself. This prince began, in 1661, to interfere in the controversy, and to persecute the Jansenists, who were already out of favour at court for preaching repentance and boldly censuring the vices of the age. But their interest with the French clergy and the influential men of the kingdom was such, that it was found impossible to force them to an unconditional subscription of the bull of Alexander VII.; and, in 1668, the agreement with Clement IX., by which a conditional subscription was permitted them, and the misunderstanding between the courts of Rome and Versailles, about the affairs of Spain, obtained for them a temporary repose. They lost, in 1679, their principal patron, Anna, duchess of Longueville, celebrated in connexion with the Fronde, and sister of the great Condé; and Arnauld, to escape persecution, retired in the same year into the Netherlands, where he continued till his death, in 1694, the most zealous and esteemed defender of Jansenism; but, notwithstanding these losses, the party stood its ground under the protection of Innocent IX. (died 1689), a friend of virtue and justice, who favoured them as much as Louis XIV. and the Jesuits opposed them. The Jansenists made themselves worthy of this protection, and of the favour of the better part of the educated men in France. By endeavouring to free theology from the chains of the hierarchy, and to promote a knowledge of the Scriptures among the people; by inculcating, in the place of formal piety and lifeless ceremonies, an ardent participation of the heart and soul in the exercises of devotion, and a strict purity of life, they rendered undeniable service to the cause of true religion; and, these being considered, their excessive austerity appears at least more excusable than the looser principles of the Jesuits. But this only rendered them more odious in the eyes of the Jesuits.

Jansenism, however, notwithstanding all the opposition to it on the part of the court, still continued to prevail. Father Quesnel's *Moral Observations* on the New Testament—the most universally read book of this period—gave it new support. The Sorbonne, in 1702, decided the celebrated case of conscience, whether a priest, suspected of Jansenism, could grant absolution, in the affirmative, and the universally esteemed archbishop of Paris, cardinal de Noailles, used his power against the Jansenists no farther than was necessary for the peace of the church. Clement XI. at first pursued the same course, but La Chaise, confessor of Louis XIV., and his successor the Jesuit Le Tellier, urged more violent measures, in which the king, to whose diseased fancy Jansenism and rebellion were synonymous, supported them. Quesnel, now at the head of the Jansenists, was struck from the list of the fathers of the oratory, and driven into exile. He died in 1709, at Amsterdam. In 1708, his *New Testament* was prohibited; the monastery of Port Royal des Champs, which was considered as the strong hold of Jansenism, was suppressed, by the royal police, in 1709, the nuns dispersed, the buildings demolished,

and the work of persecution finally crowned by the bull *Unigenitus* (in 1713), which was forced from the pope by Le Tellier. This bull, dictated no less by gross ignorance than by furious thirst of vengeance, condemned 101 propositions from Quesnel's Testament, which, according to this decree, were to be understood only in a Jansenist sense, although they were, in fact, mostly scriptural sentences, forms from the liturgy, and articles of faith taken from the orthodox church fathers. The bull, therefore, only excited indignation and contempt, and increased the numbers of the Jansenists. Louis XIV. died in 1715, during the efforts that were made to carry it into effect in France; and, taking advantage of the indifference of the regent, Noailles, with the majority of the French clergy, appealed from this decree of the pope to a general council.

Although the Jansenists were the original authors of this appeal, yet all the appellants were not Jansenists (see *Unigenitus*); but they all met with the same treatment, the ministers Dubois and Fleury, out of complaisance to the pope, insisting on the unconditional reception of the bull, and rigorously persecuting all recusants. Great numbers of Jansenists emigrated to the Netherlands; the power of their party rapidly declined, and the miracles (cures and sudden conversions) at the tomb of the abbé de Paris (who died 1727, an early victim to voluntary penances) found credit only with enthusiasts and the Parisian populace. The fanatical excesses of their party, from 1731, helped to ruin their cause. The frenzies of the Convulsionaries, or those who were seized with spasms and ecstasies at the tomb of this wonder-working saint—of the Secourists, who availed themselves of external means to produce convulsions, and had themselves tormented with kicks, blows, and stabs—of the Naturalists and Figurists, who sometimes strove to represent the helplessness of human nature unaided by grace, and sometimes the purity of the Christian church, by indecent exposures of the body—of the Discernants and Melangists, who divided on the question whether the raptures were produced by God or the devil—these, and other fanatical sects of Jansenists and Appellants, must have necessarily made a thing, of which the world was already tired, utterly ridiculous; and the energetic measures of the police, the continual burning of Jansenist books, the frequent imprisonments, but, most of all, the very natural subsiding of enthusiasm, at last put an end to the party. From this time, Jansenism ceased to exist in France, as a public and professed doctrine. Its pure morality and strict theology always gained for it friends, however, even in that country; and a part of the clergy, by their willingness to take the constitutional oath, during the revolution, showed that they would more readily renounce the authority of the pope than their own opinion. But though the old division of the Jansenists and Molinists continued up to the latest times, in the opposition between those who took and those who refused the oath (*prêtres insermentés*), yet we find but one separate society of the Jansenists, publicly acknowledged as such, and that in the Netherlands, which, in accordance with the resolution of the Jansenist provincial synod at Utrecht (1763), does not separate from the Catholic church, and even respects the pope as its spiritual head, but denies his infallibility, rejects the bull *Unigenitus*, and appeals from it to a general council. It maintains, also, the doctrines of Augustine, upholds moral strictness, and regards the inward service of God as the greatest proof of piety. These Jansenists, who call themselves, by preference, the *disciples of St Augustine*, have had, since 1723, an archbishop of their own at Utrecht, and bishops at Haarlem and Deventer,

forming a clergy which, being subject to the civil authority, without riches or power, performs its duties so much the more faithfully, and exercises a well ordered church government, which they owe to the protection of Protestants, while they are still condemned by the pope as apostates and schismatics.

JANUARIUS, Sr, bishop of Benevento, was beheaded at Pozzuoli, in the beginning of the fourth century, a martyr to the Christian faith, and is honoured as the patron saint of the kingdom of Naples. In honour of him, the order of St Januarius was established there, in 1738. His body lies buried in the cathedral at Naples; but his head, with two phials of his blood, which a pious matron caught, as the tradition is, at his execution, is preserved in a separate chapel. Of this blood, the Neapolitans assert, that as soon as it is brought near the head of the saint, it begins to flow, however hard congealed it was before. A trial is made every year, on the first Sunday of May; it is believed, that the patron saint is particularly propitious if the blood moves briskly in the phials, and appears of a clear red, while the opposite is regarded as presaging some ill to the country. The religious phrensy which prevailed at certain festivals of the ancients, has a counterpart in the clamour for the liquefaction of the blood of St Januarius, in the chapel of this saint, if it is delayed long after the commencement of the celebration. The writer, who was present on one of these occasions, could hardly determine whether the prevailing tone was that of prayer or imprecation. The reproaches against the saint are not a few. Sometimes, two or three days elapse before the blood becomes liquid; it is in a bottle, which stands upon the altar, and is lifted, now and then, by a priest, to show to the people whether it has become liquid or not; if it has liquefied, all throng to the altar, and, kneeling down, kiss the offered bottle, and then the priest presses it against the head of the faithful. It is said, that when the French occupied Naples for the first time, the blood would not become liquid. The French general, apprehensive of a commotion, sent to the archbishop, intimating, that if the saint's blood did not soon run, the archbishop's might. The archbishop had compassion on the servant, and the miracle took place in due season.

JANUS; one of the primitive deities of the Romans, entirely unknown to the Greeks, and supposed to be of Pelagic origin. The Pelasgi believed in two supreme deities, under which they represented nature and her productions. Sometimes they were described as two different beings, male and female, and sometimes as united in a single person. This deity passed from the Pelasgi to the Latins or aborigines, and received from them the name of *Janus*. In him they worshipped the god of gods (as he is called in the Salian hymns), the ruler of the year, and of all human fortunes, the sovereign disposer of war and peace. He was represented with a sceptre in the right hand, and a key in the left, seated on a glittering throne; he was also represented with two faces (an old and a youthful one), of which one looked forward and the other behind. Some conceive this to be a symbol of wisdom which sees into the past and the future; others a symbol of the changes of the year, the vicissitudes of the seasons, or of the several quarters of the world, as he was sometimes painted with four faces, and of his double office of opening and shutting the gate of heaven. Plutarch explained it by supposing that Janus had introduced agriculture from Thessaly into Latium, and hence one head looked towards Latium, the other towards Greece. Some believe that Janus was blended in one person with the other supreme deity of the original inhabitants of Italy, viz. Saturn. In reference to this co-

circumstance, they relate the following story: Janus, one of the ancient kings of the Latins, taught his people agriculture, and introduced useful laws and religious institutions. Saturn, driven from his country by his children, fled to Latium, where he was well received by Janus, and made joint ruler of the kingdom. Under their reign was the golden age of Latium. Ovid, in his *Fæsti* (i. 90, sqq.), says of Janus, that he was the supreme janitor in heaven and on earth, that he opened the gates of heaven to let out the day, and closed them again with the return of evening. All sorts of passages were under his care. After him, a door was called *janua*, and every open arched passage, by which people go out of one street or place into another, a *Janus*. For the same reason, he was the god of the day and the year, and from him the first month in the year still has its name. The first day of the year and the first hour of the day were sacred to him; in all solemn sacrifices he was the first addressed, and had the title of *father*. Romulus erected to him the celebrated temple, which was opened at the beginning of every war, according to the ordinance of Numa, and remained open as long as the war lasted, and until peace was established in all the countries subject to Rome. The temple, however, was shut only three times in the long space of 700 years; once in the reign of Numa, again after the first Punic war, and the third time, under the reign of Augustus, A. U. C. 744.

JAPAN. At the eastern extremity of Asia, between 31° and 49° N. lat., is situated the empire of Japan, consisting of a large cluster of islands, almost inaccessible by reason of mountains, precipitous rocks and a dangerous sea. It consists of three large islands: 1. Nippon (700 miles long, but so narrow, that its breadth in the centre is only forty-eight miles), divided into forty-nine provinces, of which the principal cities are Meaco, the residence of the daimi, or spiritual chief, where all the coins are struck, and all the books printed; Jeddo (with 1,680,000 inhabitants), the residence of the secular emperor (cubo, whose palace is five leagues in circumference, and forms, of itself, a considerable city), on the river Tonkay, over which is a bridge, from which the distances of all parts of the empire are calculated; and Osacco, a rich commercial city: 2. Ximo, or Kiusiu (186 miles long, and sixty-six broad), consisting of nine provinces: and 3. Xicoco, or Sicof (eighty-four miles long, forty-six broad), containing four provinces. Around these great islands lie a vast number of small fertile islands and bare island-rocks, which have probably been separated from the main land by an earthquake. The superficial contents of the whole island, is estimated at 266,500 square miles, the population at forty-five millions.

The Japanese islands are mountainous, like the opposite coasts of the continent. The principal summit is called *Fusi*; it is covered with snow throughout the year. There are also many volcanoes. The great industry of the natives has alone made the sterile soil productive; even the steepest mountains are cultivated. Agriculture is prescribed as the principal employment, by the laws of the state. Goats and sheep are banished from Japan, the former being regarded as prejudicial to agriculture. Cotton and silk supply the place of wool. Swine are to be found only in the vicinity of Nangasacki. In general, there are but few quadrupeds in Japan, with the exception of dogs, which are abundant. The whim of a sovereign, of whom these animals were favourites, has prescribed the breeding of them by a law of the state; they are supported at the public expense.

It is uncertain whether the ancients knew any

thing of Japan. At the end of the thirteenth century, Marco Polo brought to Europe the first accounts of Japan, which he called *Zipangu*. In 1542, three Portuguese ships under Mendez Pinto, on a voyage to China, were driven on the Japanese coasts by a storm, though without this accident this island empire would hardly have remained unknown to the enterprise of this commercial nation, whose navigators had collected information respecting it in China. A colony was immediately founded on the newly discovered coast, and the Jesuit Francis Xavier proceeded to Japan to propagate Christianity. The Portuguese were allowed free access and commerce throughout the empire, especially on the island Ximo. One of their principal colonies was on the island of Firando, now Desima, or at the port of Nangasacki. Christianity prevailed extensively, though opposed by the native priests. But the secular rulers, especially the small princes who possessed portions of the country under the supremacy of the emperor, supported the new doctrine and its preachers. About the year 1616, nearly half were Christians, with many of the petty princes. The Portuguese and Jesuits had been allowed uninterrupted access to all parts of the empire as merchants and spiritual teachers for about fifty years, when several circumstances put an end to their influence. In 1586, a revolution deprived the emperor of Japan of all temporal power, which was usurped by the cubo, the chief officer of the government, who degraded the emperor to the rank of a mere high priest. Jejas, the successor of the first usurper, made, in 1617, the sovereignty hereditary in his family. Both the new rulers were enemies of the Portuguese and missionaries, as they saw presages of danger in the close union of the new religious party, and in the influence of the Jesuits, who interfered in political affairs, and opposed the new order of things. The conduct of the Portuguese colonists was in the highest degree imprudent and licentious. The ambassadors of Portugal manifested an insupportable pride, which formed a strong contrast with the submission of the Dutch, who had obtained free intercourse with all the ports of the empire, by their assurance that they were of a different creed from the Jesuits. After many persecutions, the Portuguese, with their missionaries, were finally banished for ever from the empire, in the year 1637; Christians were exposed to bloody punishments, and the ports of the empire were closed to all foreigners, except the Dutch. This persecution of the Catholic religion continued forty years, in which time several millions of men were sacrificed. In 1665, inquisitorial tribunals were erected in all the cities of the empire, which were to renew their investigations, every year, at indefinite periods. The Dutch, who contributed not a little to this catastrophe, now took the place of the Portuguese. They and the Chinese were from this time the only nations whose ships were allowed access to Japan; but both had to submit to the severest conditions, and were very much limited in their exports, and the former were so restricted after 1634, when they had given cause for suspicion, that they were only permitted to land on the island Desima, connected by a bridge with the city Nangasacki. On this island, where their storehouses were situated, lived about fifteen Dutchmen, who carried on the trade, under the closest inspection, never being permitted to enter the city without attendants, overseers and interpreters. Notwithstanding these restrictions, and the extortions to which the Dutch had to submit, in the shape of deductions from the prices agreed upon, and arbitrary changes in the value of coins, their trade with Japan seems to have been very profitable, since they have continued, to the latest times, to send

thither yearly two vessels from Batavia, large three deckers, mostly belonging to Zealand. In the middle of the eighteenth century, the profits of the Japanese trade were estimated at 4—500,000 guilders annually. In the seventeenth century, the British founded a colony at Firando, and obtained important commercial privileges; but this commerce was soon lost, probably because the Japanese learned from the crafty Dutch, that the wife of the king of Britain was a Portuguese princess. All proposals for opening a trade with Japan have of late been rejected in Britain, because the return cargoes must consist principally of copper and camphor, and the trade in Japanese copper would prevent the exportation of the British to India. The Russian government has lately tried, but without success, to form commercial connexions with Japan.

The Japanese are a mixture of the Malay and Mongolian races, like the Chinese, from whom they have probably derived their civilization. The Japanese art, calculation of time, medicine, and astrology are purely Chinese. The present inhabitants originated either from China or Corea, or from both; but, separated by tempestuous billows from the rest of the world, left to themselves, and free from the subsequent invasions of neighbouring nations, they became an independent people. Their language is a dialect of the Mongolian; the Chinese is the learned language. The Japanese language has forty-seven radical syllables, with a small number of regular changes. The Japanese are the most civilised and refined nation of Asia, a noble, proud people, intelligent, docile, and desirous of instruction. Art and science they value, even in nations whom they otherwise despise for their unworthy conduct, and the shameful treatment to which they are willing to submit for the sake of gain. Since the arrival of the Europeans, by whom they were taught, they have made considerable progress in several sciences. History, astronomy, and medicine (in which cautery or burning with moxa, and acupuncture are practised), are pursued with zeal. Their progress, however, in medicine and geography, is comparatively small. Poetry, music and painting are held in estimation; and, in the latter, the Japanese are superior to the Chinese. Like the Chinese they claim the invention of gunpowder and of printing. Children are sent to school at an early period, and educated with great strictness. The exportation of books is prohibited, at least, of such as contain any account of the government and country, as well as of maps and coins. The importation of religious books is as strictly forbidden.

The Japanese are active, cleanly and laborious, kind, cheerful and contented, but sensual and revengeful. The following represents the female costume:—

Their superstition is encouraged by a priestly government, opposed to all intelligence, and a numerous clergy. The government is despotic and severe, and the laws very strict. The will of the emperor is the supreme law; after it, the will of the petty princes dependent on him, who rule their provinces as strictly as he does the whole empire, and notwithstanding their dependence, possess the right of waging war against each other. The greater part of the inhabitants are oppressed by poverty, since the peasant is obliged to surrender half, and in many places even two-thirds of his earnings to the landlord, who regards himself as the sole proprietor of the soil. In order to prevent conspiracies, each one is made, by the law of the land, the spy, and surety of the others; so that every one is accountable to the state for those with whom he is in any way connected, and, in case of any offence, must suffer with them. Thus the father is accountable for his children, the master for his servants, the neighbour for his neighbour, every society for its members. A crime is never punished by fine, but always by imprisonment and banishment, or loss of limb or life; and every punishment is inflicted with inexorable rigour on high and low. All military and civil officers, for example, are bound to slit their belly, when ordered to do so, in consequence of any crime. Such a death involves no disgrace, and hence the contempt of death among all classes of Japanese, who, in general, prefer death to ignominy.

The original rulers of Japan were called *mutado*, from their progenitor. The high priest of Japan is still called *dairi*, which was the title of the Japanese emperors as long as they possessed spiritual and temporal powers united. Since the revolution, which deprived them of the secular power, in 1185, when Yori-Tomo was appointed supreme ruler of the nation, the high priest has lived at Meaco. Under the present reigning dynasty of the Djogouns, his authority has declined still more. He is in the custody of a governor, answerable to the secular emperor. In order to make himself more sure of the descendants of the ancient rulers of Japan, the crafty policy of the secular emperor has transmuted the *dairi* into a holy personage, who is visible to no human eye, at least to no man who is not in attendance on him. Whenever the *dairi*, as is very rarely the case, wishes to enjoy the fresh air in his garden, or in the inner circle of his extensive and well fortified palace, a signal is given for all to withdraw, before the bearers raise the holy prisoner on their shoulders. In this palace, where he was born, he lives and dies, without ever going out of its precincts; and not till long after his death is his name disclosed beyond them. He enjoys a rich income, consisting of merchandise and natural products, which the secular emperor increases by considerable additions, and by the proceeds of the sale of titles of honour, which belong to the *dairi*, as a prerogative. Orders are also issued in the name of the *dairi*. The secular emperor bears the title of *cubo*, and resides at Jeddo. Under him, the real, absolute sovereign of the empire, are the princes, who are responsible to him. He concedes, however, the first rank to the *dairi*, accepts from him titles of honour, and rewards the distinction thus bestowed on him by considerable presents. Formerly, the *cubo* made an annual journey to Meaco, in token of respect to the *dairi*; by degrees, these visits became less frequent, and now, as a substitute, presents are sent him by ambassadors. The *cubo* administers the government, with the assistance of a council of state, of six aged men. He derives his revenues, which consist merely of natural productions, from five *imperial provinces*, as they are called, and some cities, which are under his immediate jurisdiction; in ad-

dation to which, he receives presents from the territorial princes, who govern the provinces. Each of these princes possess an hereditary sovereignty in his own province; he receives the revenue without giving an account to the emperor, and defrays the expenses of his court and his army, repairs the highways, and, in short, provides for all public expenditures; but, in token of his dependence, he is obliged to spend six months every year at the court at Jeddo, where his wives and children live in a kind of captivity, as hostages and pledges of his fidelity.

The religion of the Japanese is of Hindoo origin. This is true of the older sect of the Siutos, as well as of the more modern one of Budso or Fo, which came from China. Besides these sects, there are others, more or less resembling them. The people worship a great number of inferior divinities, whose statues are placed in the temples of the great deities. The numerous clergy, and the monks and nuns, who live in a multitude of monasteries, are under the daira. The Hindoo religion has nowhere been more disfigured by superstition and subsequent additions than in Japan. The Siuto or Confucius sect, a philosophical sect, resembles the sect of the learned in China, and despises the folly of the popular belief.

The army of the Japanese consists, in time of peace, of 100,000 men, besides 20,000 horsemen, clad in armour; the infantry are protected only by helmets; their arms, bows, muskets, sabres and daggers, are excellent; they have very heavy cannon, but are even less skilful in the use of them than the Chinese. The single princes maintain, besides, 368,000 infantry and 33,000 cavalry. The navy is insignificant. The daira formerly had large fleets, and large vessels of cedar; but now the Japanese vessels are small, at most ninety feet long, like the Chinese. In war, the Japanese display much courage, which is inflamed by martial songs and stories.

The Japanese are well situated for commerce. Formerly their ships covered the neighbouring seas; and before the arrival of the Europeans, they carried on a considerable trade, and an extensive navigation; they had, for example, visited the north-west coast of America, beyond Beering's straits, farther than the European navigators; they visited China and the East Indies as far as Bengal. After it had begun to be feared that foreigners would overthrow the state, and pervert the morals of the natives, all foreign commerce and navigation were prohibited. Their silk and cotton cloths, their porcelain wares, and their lackered tin ware, with raised flowers or figures (japanned ware), are well known, and in much demand as articles of commerce; their steel-work is excellent, especially their swords and other arms, the exportation of which is strictly forbidden.

Respecting the history of Japan, see Thunberg's *Travels* (from the Swedish, London, 1795), and Kampler's *History of Japan* (translated from the manuscripts into English, London, 1728). Compare, also, Golownin's *Narrative of his Imprisonment in Japan*, 1811—13 (London, 1817), Abel Rémusat's *Mémoires sur la Dynastie régnante des Djoouins, Souverains du Japon* (Paris, 1820), which Titsingh, who was fourteen years Dutch resident at Nangasacki, compiled from Japanese originals. The *Elements de la Grammaire Japonaise* (from the Portuguese manuscript of father Rodriguez, Nangasacki, 1604), *traduits du Portug. par Landresse, enrichis par Ab. Rémusat* Paris, 1825), is preferable to the Japanese grammars of Alvarez and Collado.\*

JAPANESE CYCLE AND ÆRA. See *Epoch*.

JAPANNING is the art of varnishing in colours. All substances that are dry and rigid, or not too flexible, as woods, metals, leather, and paper prepared, admit of being japanned. Wood and metals require no other preparation than to have their surfaces perfectly even and clean; but leather should be securely stretched, either on frames or on boards, as its bending would crack and force off the varnish. Paper should be treated in the same manner, and have a previous strong coat of size; but it is rarely japanned, till converted into *papier maché*, or wrought into such a form that its flexibility is lost. The article to be japanned is first brushed over with two or three coats of seed lac varnish, to form the *priming*. It is then covered with varnish, previously mixed with a pigment of the tint desired. This is called the *ground colour*; and, if the subject is to exhibit a design, the objects are painted upon it in colours mixed with varnish, and used in the same manner as for oil painting. The whole is then covered with additional coats of transparent varnish, and all that remains to be done is to dry and polish it. Japanning requires to be executed in warm apartments, and the articles are warmed before the varnish is applied to them. One coat of varnish also must be dry before another is laid on. Ovens are employed to hasten the drying of the work. The same pigments which are employed in oil or water answer also in varnish. For painting figures, shell lac varnish is considered best, and easiest to work; it is therefore employed, in most cases, where its colour permits. For the lightest colours, mastic varnish is employed, unless the fineness of the work admits, or its durability requires the use of copal dissolved in alcohol.

JAPHETH, a Hebrew word, signifying *beautifully producing*, is the name of the third son of Noah. His descendants, according to Genesis, x. 5. peopled the isles of the Gentiles. This is supposed to mean Southern Europe, and thus Japheth is considered the ancestor of the European race, and is believed to have been the same who is called by the Greeks *Japetos*. According to Herbelot's *Bibliot. Orient.*, the Arabians give to Japheth eleven sons, who became founders of as many Asiatic tribes.

JARED; a son of Mehalaleel's, the father of Enoch. He reached the age of 962 years, according to Genesis, v. 20.

JARL, in the early history of the northern European kingdoms; the lieutenants or governors, appointed by the kings over each province. At a later period, only one jarl was appointed in each kingdom, and the title of *duke* given him, as was the case in Sweden, for instance, in 1163. In Norway, after 1308, during the reign of Hacon VII. this dignity was conferred only on the earls of Orkney

Netherlands in Japan, has transmitted a work to the Asiatic Society of Paris, on the origin of the Japanese, &c., containing, in an abridged form, the result of his researches during the last four years. The doctor wishes it to be published at the expense of the society, with notes and a critical preface. He writes, also, that he has collected the largest library of books which he believes was ever formed in Japan; it consists of more than 1500 volumes. His zoological museum contains more than 3000 specimens, and his botanical collection about 2000 species, in upwards of 6000 specimens. Assisted by his colleague, doctor Burger, he has also formed a complete mineralogical collection. He has visited the most remarkable cities, determined their latitude and longitude, and measured the height of several mountains. He has also established a botanical garden at Dextima, at the expense of the government of the Netherlands, in which there are now more than 1200 plants cultivated. The doctor has also presented to the king of France a collection of plants in domestic use in Japan, which he considers to be well adapted for the climate of the south of France."

\* The following notice appeared in the newspapers in 1820: "Doctor Siebold, the resident of the king of the

and the princes of the blood. See the articles *Earl*, and *Alderman*.

**JASMINE**; a beautiful genus of plants belonging to the *diandria monogynia* of Linneus. The corolla is funnel-shaped, and the fruit a two-seeded berry. Thirty species are known, which are shrubs, often with long, twining branches, bearing simple or compound leaves, and beautiful and delightfully fragrant flowers. Two species are natives of the south of Europe.

**JASON**; son of *Æson*, king of *Iolchos*, in *Thessaly*, and of *Polymeda* (according to some writers, of *Polymete*, *Alcimedea*, *Polypheme*, &c.); a hero of ancient Greece, celebrated for his share in the Argonautic expedition, before which he had distinguished himself in the Caledonian hunt. His instructor was the Centaur *Chiron*, who educated most of the heroes of that time. His father abdicated the government of *Iolchos* before Jason was of full age; on which account his uncle *Pelias* administered the government as his guardian. The causes of Jason's expedition to *Colchis* are commonly related thus: *Pelias*, Jason's uncle, sent an invitation to all his relations, and, among the rest, to Jason, to attend a solemn sacrifice to *Neptune*. When Jason, on his way to *Iolchos*, came to the river *Evenus* (*Enipeus*, *Anaurus*), he found *Juno* there, in the form of an old woman, who requested him to carry her over. He complied with her request, but lost one of his shoes in the mud. *Pelias*, who had been warned by an oracle, that he should be deprived of his kingdom and life by the man who should come to the sacrifice without shoes, was alarmed at the sight of Jason in this condition, and asked him what he would do to the man designated by the oracle as his murderer. Jason, at the instigation of *Juno*, replied, that he should send him to *Colchis*, after the golden fleece; and he was accordingly sent. Another account relates that *Pelias* had deprived his brother of his throne, and that Jason, when twenty years old, having asked the oracle how he could get possession of his lawful inheritance, was directed to go to the court of *Pelias*, at *Iolchos*, in the dress of a *Magnesian*, with a leopard's skin on his shoulders, and armed with two lances. On the way, Jason lost his shoe in the manner above related. All were surprised at his appearance, and *Pelias*, who did not recognise him, demanded who he was. Jason answered boldly that he was the son of *Æson*, caused himself to be shown the dwelling of his father, and spent five days there with his relations, *Pheres*, *Neleus*, *Admetus*, *Amythron*, *Acastus*, and *Melampus*, in celebrating his return. They then went together to *Pelias*, and demanded of him his abdication. *Pelias* dared not refuse, but answered that he would resign, after Jason had performed a glorious achievement by bringing back the golden fleece to *Thessaly*, as the oracle and the shade of *Phryxus* had commanded, since his age would not permit him to go himself. On the voyage (see *Argonauts*), Jason had two children by *Hypsipyle* of *Leinnus*—*Euneus* and *Nebrophonus* (*Deipylus*). By the assistance of *Medea* he successfully accomplished the object of his voyage, and returned, carrying home *Medea* as his wife, after long wanderings. Here he avenged the murder of his parents and his brother, by putting *Pelias* to death. But he was unable to retain possession of the throne, and was obliged to resign it to *Acæstus*, son of *Pelias*, and flee, with his wife, to *Corinth*. Here they passed ten happy years, till Jason, wearied of *Medea*, fell in love with *Claude* (*Creusa*, according to some accounts), daughter of *Creon*, king of *Corinth*, married her, and put away *Medea* and her children. *Medea*, having revenged herself on her hated rival, fled from the wrath of Jason, in her car drawn by dragons, to

*Ægeus*, king of *Athens*, after she had put to death *Mærmærus* and *Phæretus*, her sons by Jason. According to some, Jason killed himself in despair; but others relate that, after passing a miserable wandering life, he came to his death by the following accident: As he was sleeping one day, overcome by weariness, on the sea-shore, in the shade of the vessel which had borne him to *Colchis*, a beam fell upon him and crushed him. Others say that he was afterwards reconciled to *Medea*, and returned with her to *Colchis*, where, after the death of his father-in-law, he ruled many years in peace.

**JASPER**. See *Quartz*.

**JASSY** (*Jash*), capital of *Moldavia*, about 15 miles distant from the *Pruth*, 200 miles east of *Oczakow*, 370 north of *Constantinople*, has a citadel, and is the residence of the hospodar, and seat of the Greek metropolitan of *Moldavia*, with 25,000 inhabitants. The Roman Catholics are allowed the free exercise of their religion, and there are some Jews here. The city is an open place, and was almost destroyed by the janissaries, August 10, 1822: it now contains hardly 2000 houses. The streets are paved with logs. The excellent canvass made here, and the wine of *Catanapou*, in the neighbourhood, are exported from *Jassy* to *Constantinople*. This city was taken by the Russians, in 1739 and 1769, but each time restored to the Turks on the conclusion of peace. In 1788, it fell into the power of the Austrians; and, January 9, 1792, the peace between Russia and Turkey was signed here. (See *Russia*.) In 1821, the unfortunate Alexander *Ypsilanti* here raised the standard of the Greek *Heteria* against the Turks. See *Heteria*, and *Greece*, *Revolution of*.

**JAUCOURT**, *Louis*, chevalier de, one of the contributors to the French *Encyclopédie*, born 1704, at *Paris*, received the rudiments of his education at *Geneva*, passed three years at *Cambridge*, and studied medicine in *Holland*, under *Boerhaave* and *Tranchin*, but determined to practise it only for the benefit of the poor. On his return home, he devoted himself entirely to letters, and, at the instance of *D'Alembert*, he prepared the articles relating to medicine and natural philosophy for the *Encyclopédie*. He also contributed other articles, which are among the best in the work. Feeling his strength decline, he retired to *Compiègne*, where he died, 1779. Besides his treatises in the *Encyclopédie*, he published various works, some original and some translated, on medical subjects. The manuscript of a universal medical dictionary, which he had prepared, in six volumes, folio, was lost on its way to the publisher in *Amsterdam*, in a vessel that was shipwrecked on the coast of *North Holland*.

**JAUNDICE** is a disease of which the distinguishing peculiarity is, that the whole skin becomes yellow. It proceeds from some disease about the liver, or its communication with the bowels. The internal symptoms are those of all disorders of the digestive organs, except that the water is dark and loaded with bile, while the bowels appear to be deprived of it. The yellow colour is first perceptible in the whiter parts of the body, as the white of the eye, &c., and soon overspreads the whole body. There is often an extreme itching and pricking over the whole skin. After the disease has continued long, the colour of the skin becomes gradually deeper and darker, till the disease becomes, at last, what is vulgarly called the *black jaundice*. This appearance arises from the bile being retained, from various causes, in the liver and gall-bladder, and thus being absorbed and circulated with the blood. It may be produced by obstacles to the passage of the bile of various kinds, and is often suddenly induced by a violent fit of passion, or more slowly by long con-

timance of melancholy and painful emotions. It is a very common figure of speech, to say, that "a person views a thing or a person with jaundiced eyes;" but this is founded in a mistake; for it is not true, that jaundice communicates such a colour to the transparent part of the eye, as to affect the colour of objects. The above phrase is therefore inappropriate.

JAVA; a large island in the Eastern seas, situated between 6° and 9° of S. lat., and between 105° and 115° of E. lon. from Greenwich. It extends from east to west, and is 642 miles in length, its greatest breadth 128 miles, and its average breadth ninety-five. To the south and west, its shores are washed by the Southern Indian ocean; to the north-west lies the island of Sumatra, from which Java is separated by a strait, twenty miles wide in the narrowest part, known by the name of the *Straits of Sunda*; to the north is Borneo; to the north-east, Celebes; and, on the east, the islands of Bali and Madura, from the former of which it is separated by a narrow passage, called the *Straits of Bali*. The island is divided nearly in its whole length by a range of mountains, running almost east and west, and rising to their greatest elevation towards the centre; but the range is much broken. In several hills of the great range of mountains are the craters of volcanoes, which formerly raged with fury, and poured forth torrents of lava; but, at present, none are known to be in activity, though many emit smoke after heavy rain. The most considerable rivers are the Joana, and the Sedani, or Tangerang. On the bank or bar before Batavia, the flood rises about six feet, and higher at spring tides. High and low water likewise occur only once in twenty-four hours. The island is traversed from east to west by a great military road, 700 miles in extent, constructed by general Daendels, a governor of the island, before it was taken by the British. The year, as is usual in tropical climates, is divided into the dry and the rainy seasons; or into the east, which is called the *good monsoon*, and the west, or the *bad monsoon*. Thunder storms are very frequent, especially towards the conclusion of the monsoons, when they occur almost every evening. The heat of the climate is various. Along the sea-coast, it is hot and sultry. At Batavia, from July to November, the thermometer generally stands, in the hottest part of the day, between 84° and 90°, which it rarely exceeds; and, in the greatest degree of coolness in the morning, it is seldom lower than 76°. In some parts, particularly among the hills, and in many of the inland towns, it is often so cold as to make a fire desirable. Java possesses a soil of extraordinary luxuriance and fertility. In the forests, especially in those on the north-east coast, is found an abundance of lofty trees, fit to be converted into masts, while forests of teak supply the place of oak for building ships, adapted to all purposes. Palms and cocoa-trees are found in great variety, and are distinguished by their luxuriant growth, sometimes reaching to the astonishing height of 150 feet. Fruits of all kinds are also abundant, many of them of exquisite delicacy and flavour. In the high ground in the interior, they are found to dwindle and degenerate, in that equinoctial climate. The various kinds of plants, and great abundance of herbs found in Java, could afford ample scope for the researches of the botanist, as flowers exhale their perfumes at all seasons of the year. Garden-plants are produced in great variety, such as endives, cauliflowers, beans, eggplants, pumpkins, melons, patacas or water-cucumbers, yams, potatoes, &c. Maize, or Indian corn, is a favourite article of food with the natives, who eat it roasted. The natural fertility of the soil of

Java supersedes the necessity of laborious tillage. The staple produce of the island is rice. Sugar, to the amount of 10,000,000 of pounds annually, is also made. Pepper is produced in great abundance and perfection; also indigo of a very superior quality. Cotton is cultivated in almost every part of the island; and the coffee plantations are extremely luxuriant. The soil is also very favourable to the growth of tobacco. There are many other herbs and plants, both medicinal and balsamic, that are but imperfectly known to Europeans. Wheat and barley are only grown in small quantities, on the hilly tracts, chiefly in the middle parts of the island. Oats and Bengal grain thrive likewise in those parts of the island, and would be produced in great abundance, were due attention given to their culture. The domestic animals in Java are buffaloes, and cattle of every description, and sheep, goats, and pigs. Game, however, does not abound here so much as in other countries, though hares and rabbits are pretty common; and deer and antelopes are also plentiful. The horses, which are very numerous throughout the island, are small, but active. Wild hogs and monkeys are found in all the jungles. The forests abound with tigers, as powerful and as large as in Bengal. A species of black tiger, which is often found, is very ferocious. The rhinoceros is sometimes met with. Snakes are found here, as in all other hot countries, in great numbers, and of various kinds. Some of these are from twenty-five to thirty feet in length. Lizards of all kinds, from the variable chameleon to the guana tribe, frequent the bushes, trees, and roofs of the houses. Scorpions and mosquitoes abound in the marshes. There are, besides, various other sorts of dangerous and disgusting vermin. Of the numerous feathered tribes found in Java, we may remark the cassowary, a very large and powerful bird. White eagles have been seen here; and every kind of bird of prey is continually on the wing. The aquatic tribe is equally diversified, and the extensive fisheries along this great line of coast are highly productive. At the mouths of the rivers, numbers of alligators, or caymans, are continually lurking for their prey. In the several bays, numerous sharks swim about the ships; and many animals, undescribed in natural history, abound in these seas. There are manufactures of cotton, leather, and saddlery; also of iron, brass, and tin. The principal articles of exportation are rice, sugar, coffee, pepper, indigo, teak timber and planks, spices (which are brought from the Moluccas), tin (from Banca), cotton, yarn, salt, edible birds' nests. The imports are European articles, of every description—chintzes and muslins, silks, hats (which are a favourite dress with the Chinese and native chieftains), boots and shoes, cabinet ware, fire-arms, gunpowder, shot, haberdashery, hosiery, mathematical and musical instruments, &c. The population of Java is composed almost entirely of natives, of a variety distinct from the Malays and other inhabitants of the neighbouring islands. In 1815, it amounted to 5,000,000, of whom one-fortieth part were Chinese, Europeans, Arabs, Malays, and Hindoos. The Javanese are small, with a yellow complexion, flattened nose, high cheek bones, and thin beard. Their language is entirely different from the Malay; their religion Mohammedanism. Numerous monuments of antiquity, buildings, statues, &c., prove that they were once in a more flourishing condition than at present. Three quarters of Java are in the power of the Dutch, whose immediate authority extends over three-fifths of the inhabitants. The other quarter is divided between two native sovereigns in the south-east part of the island. Java was discovered by the Portuguese in 1510. They made some settlements there, which

were taken possession of by the Dutch, towards the end of the sixteenth century. The latter, having conquered the native princes, made the island the centre of their Indian possessions in 1619. In 1811, the British made themselves masters of it, but restored it at the peace of Paris, in 1814. The exactions and oppressions have since occasioned several insurrections of the natives.—See Raffles's *History of Java* (second edition, London, 1830); Crawford's [British resident at Java] *Indian Archipelago*; Marchal's *Descript. Géog., Hist., et Commerciale de Java* (Brussels, 1826.) Blume, a Dutch naturalist, who resided nine years in the island, has published a view of the vegetable kingdom of Java.

**JAY** (*garrulus*). These birds are distinguished from the crows by having their bill rather short and straight; upper mandible somewhat inflected at tip; lower, navicular; head feathers, erectile; wings, not reaching to the tip of the tail; colours, brilliant. The European jay (*G. glandarius*) and the blue jay of the United States (*G. cristatus*) are the most prominent and best known of this genus, and possess much the same characteristics, both in their wild and their domesticated state. They are lively, petulant, and rapid in their movements; exceedingly noisy, having a faculty of imitating harsh sounds. When an owl or other bird of prey appears in the woods, they utter piercing cries, and assemble in great numbers to attack the common enemy. The same thing takes place when they see a sportsman, whose purpose they often frustrate by their vociferous noise. They indulge no familiarity with man, and discover all that shyness and timidity so natural to thieves. In a domestic state, they are restless, and much addicted to transports of anger. When confined in a cage, therefore, they soon lose their beauty, by the perpetual rubbing and breaking of their feathers. Like their kindred, the magpie and jackdaw (q. v.), they can be taught a variety of words and sounds, particularly those of a harsh and grating character, as that of a saw, &c.

**JAY, JOHN**, an eminent American jurist and statesman, was born in the city of New York, Dec. 1, 1745, old style. After receiving the elements of education at a boarding-school, and under private tuition, he was placed, when fourteen years of age, at King's (now Columbia) college, in his native place. Here he devoted himself principally to those branches which he deemed most important in reference to the profession of the law, upon the study of which he entered after receiving his bachelor's degree. In 1768, he was admitted to the bar, and in 1774 was chosen a delegate to the first American congress, which met at Philadelphia, and was placed on a committee with Mr Lee and Mr Livingston, to draft an address to the people of Great Britain. It was prepared by Mr Jay, and is one of the most eloquent productions of the time. In the two following years, he was re-elected, and served on various important committees. In 1776, he was chosen president of congress. In 1777, he was a member of the convention which framed the constitution of New York; and the first draft of that instrument proceeded from his pen. The following year, when the government of New York was organized, he was appointed chief-justice of that state. In 1779, we find him again a member of congress, and in the chair of that body. From this, however, he was removed in the same year by his appointment as minister plenipotentiary to Spain. The objects of Mr Jay's mission were to obtain from Spain an acknowledgment of the independence of the United States, to form a treaty of alliance, and to procure pecuniary aid; with regard to the last only of which points, a satisfactory conclusion was obtained. In 1782, Mr Jay was appointed one of

the commissioners to negotiate a peace with Britain, at the same time that he was authorized to continue the negotiation with Spain. In conjunction with Mr Adams and doctor Franklin, he resolved to disobey the instructions of congress to follow in all things the advice of the French minister, count de Vergennes, who was embarrassing the negotiation with Britain, in order to benefit France at the expense of the United States, and accordingly they signed a treaty with the British minister, without his knowledge. The definitive treaty having been signed in September, 1783, he soon afterwards resigned his commission as minister to Spain, and, in May, 1784, embarked for the United States. He was then placed at the head of the department for foreign affairs, in which office he continued until the adoption of the present constitution, when he was appointed chief-justice of the United States. In 1787, he received a serious wound in the forehead from a stone, when acting as one of a volunteer corps to preserve the peace of the city at the time of the doctors' mob. He was, in consequence, confined to his bed for some time, a circumstance which obliged him to discontinue writing for the *Federalist*, to which he had already contributed the second, third, fourth, and fifth numbers. The only other number in the volume from his pen is the sixty-fourth, on the treaty-making power. In 1784, he was sent as envoy extraordinary to Great Britain, and concluded the treaty which has been called after his name. Before his return in 1795, he had been elected governor of his native state—a post which he occupied until 1801. In that year, he declined a re-election, as well as a re-appointment to the office of chief-justice of the United States, and retired to private life. The remainder of his days was passed in devotion to study, particularly theological, and to practical benevolence. He died, May 17, 1829, universally honoured and beloved. He was a man of inflexible firmness of mind in the performance of duty, of great discernment, extensive information, and fine talents as a writer. Although rather cautious with strangers, with friends he was affable and frank; economical in his expenses, he was at the same time generous towards every object worthy of his bounty. The letters between him and General Washington, various extracts of which are contained in the fifth volume of Marshall's history, exhibit the elevated place he held in the confidence and esteem of that illustrious man.

**JEDDO, JEDO, or YEDDO**; a city of Japan, capital of the empire, at the head of a large bay, at the mouth of a river, in the S. E. of Nippon; 160 f. by N. of Meaco. Lon. 140° E.; lat. 36° 30' N. The population has heretofore been estimated at 1,000,000. In 1812-13, the Japanese told to Golownin, that the population exceeded 10,000,000; that in the principal streets were 280,000 houses, each containing from thirty to forty persons; and that in the city there were 36,000 blind men. Meaco was formerly the capital, and is still the residence of the spiritual emperor; but the civil and military emperor has his residence at Jeddo. This city is seven miles long, five broad, and twenty in circuit. It has no walls, except those which surround the palace. It is used not to be surpassed in magnificence by any city in Asia, since, besides the usual accompaniments of a capital, all the princes and great men are obliged to make it their residence for half of the year. It contains, therefore, many splendid palaces, which stand by themselves, surrounded by large court-yards and stately gates, and, though built only of wood, and one story high, are distinguished by varnished stair-cases and large and finely ornamented apartments. The palace of the emperor may be properly called a great fortified city. It is situated in the heart of

the general city, said to be five leagues in circuit, surrounded with walls and ditches, and containing several fortified buildings, which have the appearance of castles. The outer part is composed of streets, containing many palaces, in which reside the princes of the blood, ministers, and other public functionaries. In the centre is the emperor's palace, the body of it being of only one high story, but adorned with a square tower raised many stories high. Unlike all other Japanese structures, it is well built of freestone, and is surrounded by a wall of the same material. The city is intersected by branches of the river, and by canals. It is the seat of an extensive commerce, and has many flourishing manufactures. It is greatly exposed to the ravages of fire. In 1658, 100,000 houses were reduced to ashes in forty-eight hours.

JEFFERSON, THOMAS, the third president of the United States of America, was born April 2, old style, 1743, at Shadwell, in Albemarle county, Virginia, and was the eldest of eight children. His father, though his education had been entirely neglected in early life, being a man of strong mind, acquired, by subsequent study, considerable information. He died when the subject of our sketch was about twelve years old, having previously given him every means of knowledge that could be procured, and left him a considerable estate. After going through a course of school instruction, young Jefferson entered the college of William and Mary, where he remained for two years. He then commenced the study of law under the guidance of the celebrated George Wythe, by whom, in 1767, he was introduced to its practice, at the bar of the general court of the colony, at which he continued until the revolution. In 1769, he was elected a member of the provincial legislature from the county where he resided, and made a fruitless effort, in that body, for the emancipation of the slaves. By this time, a spirit of opposition had been excited in the colonies to the arbitrary measures of the British government; and when the governor of Virginia dissolved the general assembly, in 1769, in consequence of the sympathy which was displayed by the majority of its members with the feelings which had been manifested in Massachusetts, they met, the next day, in the public room of the Raleigh Tavern, formed themselves into a convention, drew articles of association against the use of any merchandise imported from Great Britain, and signed and recommended them to the people. They then paired to their respective counties, and were all elected, except those few who had declined assenting to their proceedings. In 1773, Mr Jefferson associated himself with several of the boldest and most active of his companions in the house ("not making," as he says himself, "the old and leading members up to the point of forwardness and zeal which the times required"), and with them formed a system of committees of correspondence, in a private room of the same Raleigh Tavern. This system was adopted as the best instrument for communication between the different colonies, by which they might be brought to a mutual understanding, and a unity of action produced. This end was completely accomplished, as well as another object—of exciting throughout the colonies a desire for a general congress. It was accordingly resolved that a congress should be held, and in Virginia a convention was called for the purpose of choosing delegates. In this convention Mr Jefferson was elected a member; but, being suddenly taken ill on the road, as he was repairing to Williamsburg, its place of meeting, he sent on to its chairman, Peyton Randolph, a set of instructions which he had prepared as they were to be given to the delegates who should be sent to congress. It was laid on the table for perusal;

but, though approved by many, the sentiments contained in it were too bold to be adopted by the majority: "tamer sentiments," in his own words, "were preferred, and, I believe, wisely preferred; the leap I proposed being too long, as yet, for the mass of our citizens." The position that he maintained was, that the relation between Great Britain and the colonies was exactly the same as that between England and Scotland, after the accession of James, and until the union, and the same as her relations with Hanover, having the same executive chief, but no other necessary political connexion. In this doctrine, however, the only person who entirely concurred with him was George Wythe, the other patriots "stopping at the half-way house of John Dickinson, who admitted that Britain had a right to regulate their commerce, and to lay duties on it for the purposes of regulation, but not of raising revenue." Though the paper was not adopted, the convention, nevertheless, caused it to be printed in a pamphlet form, under the title of a Summary View of the Rights of British America. Having found its way to Britain, it was taken up by the opposition, and, with a few interpolations of Mr Burke, passed through several editions. It procured for its author considerable reputation, and likewise the dangerous honour of having his name placed on a list of proscriptions, in a bill of attainder, which was commenced in one of the houses of parliament, but was speedily suppressed. June 21, 1775, Mr Jefferson took his seat for the first time in congress, having been chosen to fill the place of Peyton Randolph, who had resigned. In this new capacity, he persevered in the decided tone which he had assumed, always maintaining that no accommodation should be made between the two countries, unless on the broadest and most liberal basis. After serving on several committees, he was at length appointed a member of that, whose report has linked the name of its author with the history of American independence. June 7, 1776, the delegates from Virginia, in compliance with the instructions of the convention, moved that congress should declare the United Colonies free and independent states. This gave rise to a warm and protracted debate; for as yet there were many who continued to cling to the hope of a peaceful adjustment. In the course of the discussion, it appearing that several colonies were not yet fully ripe for separation, it was deemed prudent to defer the final decision of the question for a short time; and, in the mean while, a committee was appointed to prepare a declaration of independence, consisting of John Adams, doctor Franklin, Roger Sherman, Robert R. Livingston, and Mr Jefferson. The last named gentleman was requested to draw up the paper, which he did; and it was reported to the house, after receiving a few alterations from doctor Franklin and Mr Adams. On the first of July, the day selected for deciding upon the original motion of the Virginia delegates, it was carried in the affirmative by a large majority, and two or three days afterwards by an unanimous vote. The declaration of independence was then brought before the house, by which, though generally approved, it was, in some respects modified. Those passages, especially, which conveyed censure upon the people of Britain, were either greatly softened, or entirely omitted, as the idea was still entertained that the colonies possessed friends among them, whose good will it would be proper to cherish; and a clause reprobating the slave-trade was cancelled, in complaisance to some of the southern States, who were largely engaged in the traffic. The debates respecting the declaration occupied three days, on the last of which, the 4th of July, it was signed by every member present, except

John Dickinson, who deemed a rupture with the mother country, at that moment, rash and premature. September 2, 1776, Mr Jefferson retired from his seat in congress, and, on the 7th of October, took his place in the legislature of Virginia, of which he had been elected a member from his county. In this situation, he was indefatigable in his labours to improve the imperfect constitution of the state, which had been recently and hastily adopted, before a draught of one which he had formed on the purest principles of republicanism, had reached the convention, which was deliberating at Richmond. The chief service which he performed was as a member of a commission for revising the laws, consisting, besides himself, of Edmund Pendleton, George Wythe, George Mason, and Thomas Ludwell Lee, by whom no less than 126 bills were prepared, from which are derived all the most liberal features of the existing laws of the commonwealth. The share of Mr Jefferson in this great task was prominent and laborious. June 1, 1779, he was chosen the successor of Mr Henry, in the office of governor of the state, and continued in it for two years, at the end of which period he resigned, "from a belief," as he says, "that, under the pressure of the invasion under which we were then labouring, the public would have more confidence in a military chief, and that the military commander being invested with the civil power also, both might be wielded with more energy, promptitude and effect, for the defence of the state." General Nelson was appointed in his stead. Two days after his retirement from the government, he narrowly escaped capture by the enemy, a troop of horse having been despatched to Monticello, where he was residing, for the purpose of making him prisoner. He was breakfasting, when a neighbour rode up at full speed with the intelligence that the troop was descending a neighbouring hill. He first sent off his family in a carriage, and after a short delay for some indispensable arrangements, mounted his horse, and taking a course through the woods, joined them at the house of a friend—a flight in which it would be difficult to discern any thing dishonourable, although it has been made the subject of sarcasm and reproach without end, by the spirit of party.

June 15, 1781, Mr Jefferson was appointed minister plenipotentiary, in conjunction with others, to negotiate a peace then expected to be effected, through the mediation of the empress of Russia; but he declined, for the same reason that had induced him, in 1776, to decline also the appointment of a commissioner, with doctor Franklin, to go to France in order to negotiate treaties of alliance and commerce with that government. On both occasions, the state of his family was such that he could not leave it, and he "could not expose it to the dangers of the sea, and of capture by the British ships, then covering the ocean." He saw, too, that "the labouring oar was really at home," especially at the time of his first appointment. But, in November, 1782, congress, having received assurance that a general peace would be concluded in the winter and spring, renewed the offer which they had made the previous year; and this time it was accepted; but the preliminary articles being agreed upon before he left the country, he returned to Monticello, and was chosen (June 6, 1783) a member of congress. It was during the session at Annapolis, that, in consequence of Mr Jefferson's proposal, an executive committee was formed, called the *committee of the states*, consisting of a member from each state. Previously, executive and legislative functions were both imposed upon congress; and it was to obviate the bad effects of this junction, that Mr Jefferson's proposition was adopted. Success, however, did not attend the plan; the mem-

bers composing the committee quarrelled, and, finding it impossible, on account of their altercations, to fulfil their duties, they abandoned their post, after a short period, and thus left the government without any visible head, during the adjournment of congress. May 7, 1784, congress having resolved to appoint another minister, in addition to Mr Adams and doctor Franklin, for negotiating treaties of commerce with foreign nations, selected Mr Jefferson, who accordingly sailed from Boston July 5, and arrived in Paris August 3. Doctor Franklin was already there, and Mr Adams having, soon after, joined them, they entered upon the duties of their mission. They were not very successful, however, in forming the desired commercial treaties, and, after some reflection and experience, it was thought better not to urge them too strongly; but to leave such regulations to flow voluntarily from the amicable dispositions and the evident interests of the several nations. In June, 1785, Mr Adams repaired to London, on being appointed master plenipotentiary at the court of St James, and in July, doctor Franklin returned to America, and Mr Jefferson was named his successor at Paris. In the February of 1786, he received a pressing letter from Mr Adams, requesting him to proceed to London immediately, as symptoms of a better disposition towards America were beginning to appear in the British cabinet, than had been manifested since the treaty of peace. On this account, he left Paris in the following March, and, on his arrival in London, agreed with Mr Adams on a very summary form of treaty, proposing "an exchange of citizenship for our citizens, our ships, and our productions generally, except as to office." At the usual presentation, however, to the king and queen, both Mr Adams and himself were received in the most ungracious manner, and after a few vague and ineffectual conferences, he returned to Paris. Here he remained, with the exception of a visit to Holland, to Piedmont, and the south of France, until the autumn of 1789, seasonably pursuing whatever was beneficial to his country. September 26 of that year, he left Paris for Havre, and, coming over to Cowes, embarked for the United States. November 23, he landed at Norfolk, Va., and, when on his way home, received a letter from president Washington, covering the appointment of secretary of state, under the new constitution which was just commencing its operation. He soon afterwards received a second letter from the same quarter, giving him the option of returning to France, in his ministerial capacity, or of accepting the secretaryship, but conveying a strong intimation of desire that he would choose the latter office. This communication was produced by a letter from Mr Jefferson to the president, in reply to the one first written, in which he had expressed a decided inclination to go back to the French metropolis. He then, however, consented to forego his preference, and, March 21, arrived at New York, where congress was in session, and immediately entered upon the duties of his post. It would be altogether inconsistent with our limits to give a minute account of the rest of Mr Jefferson's political life. This could not be done without writing the history of the United States for a certain period. We must, therefore content ourselves with stating that he continued to fill the secretaryship of state, until the 31st of December, 1793, when he resigned. From that period until February, 1797, he lived in retirement. In this year he was elected vice-president of the United States, and, in 1800, was chosen president, by a majority of one vote over his competitor, Mr Adams. At the expiration of eight years, he again retired to private life, from which he never afterwards emerged. The rest of his life was passed at Monticello, which was a continued scene

of the blandest, and most liberal hospitality. Such, indeed, was the extent to which calls upon it were made, by foreigners as well as Americans, that the closing year of his life was embittered by distressing pecuniary embarrassments. He was forced to ask permission of the Virginia legislature to sell his estate by lottery, which was granted. Shortly after Mr Jefferson's return to Monticello, it having been proposed to form a college in his neighbourhood, he addressed a letter to the trustees, in which he sketched a plan for the establishment of a general system of education in Virginia. This appears to have led the way to an act of the legislature, in the year 1818, by which commissioners were appointed with authority to select a site, and form a plan for a university, on a large scale. Of these commissioners, Mr Jefferson was unanimously chosen the chairman, and, August 4, 1818, he framed a report, embracing the principles on which it was proposed the institution should be formed. The situation selected for it was at Charlottesville, a town at the foot of the mountain on which Mr Jefferson resided. He lived to see the university—the child of his old age—in prosperous operation, and giving promise of extensive usefulness. He fulfilled the duties of its rector until a short period before his death, which occurred on the 4th of July, 1826, the fiftieth anniversary of the declaration of independence, and within the hour in which he had signed it.

In person, Mr Jefferson was tall and well formed; his countenance was bland and expressive; his conversation fluent, imaginative, various, and eloquent. Few men equalled him in the faculty of pleasing in personal intercourse, and acquiring ascendancy in political connexion. He was the acknowledged head of the republican party, from the period of its organization down to that of his retirement from public life. The unbounded praise and blame which he received as a politician, must be left for the judgment of the historian and posterity. In the four volumes of his posthumous works, edited by his grandson, Thomas Jefferson Randolph, there are abundant materials to guide the literary or historical critic in forming an estimate of his powers, acquirements, feelings, and opinions. His name is one of the brightest in the revolutionary galaxy. Mr Jefferson was a zealous cultivator of literature and science. As early as 1781, he was favourably known as an author, by his notes on Virginia. He published, also, various essays on political and philosophical subjects, and a *Manual of Parliamentary practice*, for the use of the Senate of the United States. In the year 1800, the French national institute chose him one of their foreign members. The volumes of posthumous works, in addition to an autobiography of the author to the year 1790, consist principally of letters from the year 1775 to the time of his death, and embrace a great variety of subjects.

JEFFREY OF MONMOUTH. See *Geoffrey*.

JEFFREYS, GEORGE, lord baron Wem, commonly known by the name of *Judge Jeffreys*, was born towards the beginning of the seventeenth century. He was entered at the Middle Temple, and, by attending an assize during the plague, when few barristers could be met with, he was allowed to plead, although not formally admitted, and continued to practise unrestrained until he attained the highest employments in the law. Soon after commencing his professional career, he was chosen recorder of London; and to this advancement, and the influence it procured him, may be attributed his introduction to court, and appointment of solicitor to the duke of York. A willing instrument of all sorts of measures, for farther promotion, at such a period, was rapid, and he was appointed, successively, a Welsh judge

and chief-justice of Chester, and created a baronet. When parliament began to prosecute the *abhorrrers* (or church and court party, so called from their address to the king, Charles II., expressing their *abhorrence* of those who endeavoured to encroach on the royal prerogative), he resigned the recordership, and was appointed chief-justice of the king's bench. On the accession of James II., he was one of the advisers and promoters of all the oppressive and arbitrary measures of his reign; and, for his sanguinary and inhuman proceedings against the adherents of Monmouth, was rewarded with the post of lord high chancellor (1685). He usually, however, showed himself an able and impartial judge, where political purposes were not to be answered. His deportment on the bench was, in the highest degree, discreditable at all times, and he indulged in scurrility and abuse of the most degrading description. On the arrival of the prince of Orange, the chancellor, who had disguised himself as a seaman, in order to get on board a ship unknown, was detected in a low public house in Wapping, by an attorney whom he had insulted in open court. The latter making his discovery known, Jeffreys was immediately seized by the populace, and carried before the lord mayor, who sent him to the lords in council, by whom he was committed to the Tower, where he died April 18, 1689.

JEFFRIES, JOHN, M. D., was born at Boston, in America, Feb. 5, 1744, and, after graduating at the university of Cambridge, commenced the study of medicine. After completing his preparatory studies, and being admitted to practise, he went to London, and sedulously attended the instructions of the most distinguished lecturers. June 1, 1769, the university of Aberdeen conferred on him the degree of doctor of physic, he being, as it is believed, the first native of the American provinces who obtained that honour. In the same year, he returned to Boston, where he recommenced his labours, and continued to practise, with great success, until the evacuation of that city by the British garrison. He then accompanied general Howe to Halifax. That commander made him surgeon-general to the forces in Nova Scotia, in 1776. In March, 1779, he went again to England, where he was made surgeon-major to the forces in America. In the spring of 1779, he entered upon the duties of this office in Savannah, then in the possession of the British. He did not, however, retain it very long, for, in December, 1780, he was again in London, having resigned, and proceeded thither in consequence of a severe domestic affliction. In London, he practised with considerable success, and occupied himself much with scientific research, having declined the offer of the lucrative post of surgeon general to the forces in India. To ascertain the correctness of certain preconceived hypotheses relative to atmospheric temperature, and the practicability of some aerostatic improvements which had suggested themselves to his mind, he undertook two aerial voyages. The second one was made Jan. 7, 1785, from the cliffs of Dover, across the British channel, into the forest of Guinnes, in the province of Artois, in France, and was the only successful attempt to cross the sea in a balloon. The reputation accruing from these expeditions gained him the notice and civilities of some of the most distinguished personages of the day, procured for him an introduction to all the learned and scientific societies of Paris, and facilitated his access to the medical and anatomical schools of that metropolis. He drew up a paper, detailing the result of his various experiments, which was read before the royal society of London with much approbation. In the summer of 1789, he repaired to Boston where he soon acquired eminence. It is said that

he delivered the first public lecture in Boston on anatomy, a branch of which he was very fond. He delivered, however, but one; for, on the second evening, a mob, having collected, entered his anatomical room, and carried off, in triumph, his subject, which was the body of a convict, given him by the governor after execution. After an uninterrupted and successful practice of fifty-three years, he was seized with an inflammation of the bowels, originating in a hernia occasioned by great exertion in his first aerial voyage, which carried him off on the 16th of September, 1819, aged seventy-six years.

JEHOVAH; the awful and ineffable name of the God of Israel, which was revealed to Moses. The pronunciation of this celebrated *εργαζομενος*, which means, *He who is, was, and will be, or the Eternal, Unchangeable, the Faithful* (Exod. iii. 14; vi. 3), is not known, nor is its entire signification, though it seems to contain all the tenses of the Hebrew word to be, and to imply, as above explained, *eternal and necessary being*. It reminds us of the inscription on the temple of Isis, in Egypt—"I am whatever is, was, and will be, and no mortal has ever raised my veil;" and this resemblance may perhaps be explained by the passage in Acts vii. 22, "Moses was learned in all the wisdom of the Egyptians." (See *Egyptian Mythology*, end of article *Hieroglyphics*.) How far it may be connected with the exclamation *Io*, of the Egyptians and Greeks (Diod. Sic. i. 94; Macrobi., *Saturn.* i. 18), we cannot decide. We know that the Hebrews cherished the most profound awe for this incommunicable and mysterious name, and that this sentiment led them to avoid pronouncing it, and to substitute for it, in the sacred text, the word *Adonai*, which signifies *the lord*. This custom still prevails among the Jews, who attribute to the pronunciation of the name of the Almighty the power of working miracles, and thus explain those of Christ. This religious respect for the name of God is analogous to the veneration of the Egyptians for the proper names of their deities. They may be written either in the figurative, symbolic, or phonetic characters (see *Hieroglyphics*); and, in hieroglyphic or hieratic inscriptions, which are of a sacred character, they are phonetic; but in demotic texts which are of a profane nature, the names of the gods are always expressed symbolically, and never phonetically; and Champollion has even found that some hieroglyphic names of divinities were written one way and pronounced another. The Greeks, too, were superstitiously fearful of uttering the name of *Gorgon* or *Demogorgon*, and not less afraid of calling the Furies by their names. (Euripides, *Orestes*, verses 37 and 430.) The conception of the Jehovah of the Israelites differs from all other theological conceptions of that age. No image of him was allowed. He was the invisible protector and king of Israel, worshipped by obedience to his commandments, and an observance of the ceremonies instituted through Moses; yet the Jews were not sufficiently advanced to adore their Jehovah entirely in a spiritual manner, and the popular belief attributed to him more or less of human qualities. Thus he was conceived, from the time of David, to have his residence particularly on mount Zion. Jehovah was, and still is considered, by the Jews, as the particular God of their race, the national God of Israel; and it was Christ who first represented him as the protector of all mankind, as a father, and not an object of fear, to whom the Israelites even attributed bad passions.

JELLY includes every translucent juice so far thickened as to coagulate, when cold, into a trembling mass; as the juices of acid or mucilaginous fruit, currants, &c., which, by the addition of one part sugar to two parts of juice, and, by boiling,

have obtained a proper consistence; also a coarctated decoction of Iceland moss, made agreeable to the taste by the addition of sugar or liquorice; also strong decoctions of the horns, bones, or extremities of animals, boiled to such a degree as to be stiff and firm when cold, without the addition of any sugar. The jellies of fruits are cooling, saponaceous, and acescent, and therefore are good as medicines in the disorders of the *primæ viæ*, arising from alkaline juices, especially when not given alone, but diluted with water. On the contrary, the jellies made from animal substances are all alkaline, and are therefore good in all cases in which an acidity of the humours prevails. The alkaline quality of these is, however, in a great measure, taken off, by adding lemon juice and sugar lemon to them. There was formerly a sort of jellies much in use, called *compound jellies*; these had the restorative medicinal drugs added to them, but they are now scarcely ever heard of. Animal jelly is soluble in water, glutinous, becomes fluid by heat, coagulates in the cold, combines with oils and resins, is decomposed by corrosive alkali, and gives out ammonium; when treated with nitric acid, it yields oxalic acid, and under dry distillation, yields the products obtainable from all animal substances, and can be changed into a perfectly dry substance by evaporation.

JEMAPPES; a village of the Netherlands, in Hainault, near Mons, on the Scheldt, celebrated as the place of the first great battle in the French revolutionary war, fought November 6, 1792, in commemoration of which, while under the French domination, the whole department was called *Jemappes*. The loss of this battle by the Austrians had a great influence on the public sentiment of Europe, and gave the highest impulse to the enthusiasm of the French. The consequence of this defeat—the loss of the Netherlands and of Liege by the allies—would have been still greater, if the French had not stopped their pursuit of the flying Austrian army at the Roer, instead of driving them across the Rhine. The Prussians had already retired to the Rhine after their unsuccessful campaign in 1792, when Dumouriez suddenly fell upon the Netherlands, planning the movements of his army with so much skill, and executing them with so much rapidity and decision, that the allies soon perceived that there was no want of the generals among the French. The French army was more numerous than the Austrian, which was commanded by Albert, duke of Saxe-Teschén, but the latter had the advantage of a position considered almost impregnable. The enthusiasm and heroic spirit of the French, which here displayed themselves in all their brilliancy, bore down all obstacles, and redoubt after redoubt was stormed and taken, to the chant of the Marseilles hymn. Dumouriez, who had appointed the young duke of Chartres, now king of the French, his lieutenant, commanded the centre; Dampierre and Beurnonville the right, and Perron the left wing. The loss of the Austrians was estimated at 6000 men. Eight days after, Dumouriez entered Brussels.

JEMSHID, or GIAMSHID; a Persian monarch, celebrated in Oriental history, the period of whose existence is somewhat uncertain. He is said to have ascended the throne of Persia about 800 B.C., and to have founded the famous city of Ismaïha, called by the Greeks, Persepolis. To this prince is ascribed the first establishment of public baths, the invention of tents and pavilions, and the use of lime for mortar in buildings. He instructed his subjects in astronomy, and also probably in the mysteries of Sabeism, or the worship of the heavenly bodies; but though he is represented as a wise and powerful monarch, he was unfortunate in war, and, having

been dethroned by Zahak, an Arabian king, he spent the latter part of his life in indigence and obscurity. His son Pleridoun was preserved, by the care of the queen, from the pursuit of the usurper, and ultimately recovered his father's throne. See Malcolm's *History of Persia*, two volumes, London, 1829.

JENA; a town of Saxe-Weimar, in Thuringia, at the confluence of the Leuthra and the Saale, in a romantic valley, with 60,000 inhabitants; lat. 50° 56' 28" N.; lon. 11° 37' 23" E. The environs are diversified and delightful, and contain several fine ruins. There are some manufactories at Jena, and it has a much frequented fair, but the chief support of the place is the ancient university. In 1547, the elector, John Frederic, after the unfortunate battle of Muhlberg, being conducted a prisoner through Jena, and being occupied with the design of supplying his dominions with a substitute for the lost university of Wittenberg, founded by his uncle, Frederic the Wise, was pleased with the charming valley of Jena, and advised his sons to found a university here. Three convents, with their possessions, were appropriated to this institution, which Charles V. actually chartered as a university (February 2, 1558), though not very willingly, because it was a Protestant institution. Jena has had many of the first German literati among her professors, and the late duke of Saxe-Weimar was so liberal towards it, that it became one of the most favourite universities of the Germans; but the celebration of the jubilee of the reformation, on the Wartburg, not far from Jena, where Luther translated part of the Bible, and the circumstance that Saad, the murderer of Kotzebue, studied there, induced the other German governments to prohibit, in 1819, any of their subjects from studying there. Prussia revoked her prohibition in 1825; but it has not resumed its former standing. In 1829, it contained 600 students. The university has a library of 100,000 volumes, museums, a botanical garden, an anatomical theatre, &c. It is one of the cheapest in Germany. It is also one of the few where the small sword is used in duels. Schiller, the German poet, was professor of history at Jena, which is the joint university of the Saxon duchies.

*Jena and Auerstädt, Battle of* (October 14, 1806). Placed in the most unhappy situation, since the treaty of Vienna of December 15, 1805 (see *Austerlitz*), involved in war with England and Sweden on account of Hanover, Prussia took up arms to defend the independence of Northern Germany against France; but the commander-in-chief, the duke of Brunswick, seventy-two years old, instead of penetrating immediately beyond the Rhine, and compelling the elector of Hesse, who wished to remain neutral, to unite his forces with those of Prussia, concentrated the Saxon-Prussian army in Thuringia, by which he lost not only the right moment of attack, but also all the advantages of his line of defence and communication with the Elbe, while he obstinately persisted in the opinion that Napoleon would not act on the aggressive. He discovered too late, that the left flank of the Prussian army was wholly exposed to the enemy. Napoleon, who left Paris September 25, and arrived at Kronach October 8, had achieved the victory, and the great results of the campaign before the battle was fought, by his generalship in making himself master, within five days, of the region between the Saale, Elster, and Elbe. By his preparatory movements, the left wing of the Prussian army was surrounded, and destroyed, as well as the military roads to Dresden and Berlin, now lay open to him; whereupon he pressed forward, without opposition, in the rear of the Russian army, as far as Mauburg, which Davoust

occupied October 13, while the Prussian army stretched itself from Jena to Eisenbach, and the duke took up his headquarters at Weimar, from October 10 to 12. Two important points, on the left bank of the Saale, were also occupied by the French; Jena by Lannes, and Kahla by Augereau. Napoleon himself arrived at Jena from Gera, October 13. He had previously made a proffer of peace to the king of Prussia; but the bearer of his missive of October 12, from his camp at Gera, did not reach the king till the day of battle. The double battle at Auerstadt and Jena, October 14, therefore, completed the defeat of the Prussian army, already vanquished by combinations. Napoleon was master of the points of passage on the left bank of the Saale. The Prussian army, under prince Hohenlohe, was separated from that of the duke of Brunswick; and the prince, while he guarded the *chaussée*, which led to the plain, where he expected to be attacked, permitted the enemy to occupy the steep eminences, which commanded the valley of the Muhl, at Jena; and the duke himself was equally negligent in regard to the heights and pass of Kosen. These oversights were disastrous, for Napoleon caused the most troublesome obstructions in the narrow ravines to be levelled, on the night of October 13, in order to convey his artillery to the plateau of the selected place. In the morning, a thick cloud concealed his operations. By degrees, he brought 80,000 men on the field. The left wing was led by Augereau, the guards by Lefebvre, the centre by Lannes, and the right wing by Soult. Ney subsequently advanced from the rear to the first line. Three bloody battles decided Hohenlohe's defeat. At first, the Prussian vanguard, under Tauenzien, was overthrown at Klosewitz, then the main body, under prince Hohenlohe, at Viersehnheiligen, and lastly the former right wing of the army, under general Ruchel, at Capellendorf. Thus an army of 50,000 men was completely broken up. On the same day, the duke put in motion, on the high road leading from Auerstadt to Kosen, his army of 50,000 men, in three divisions; the first, under Schmettau, accompanied by the king, three princes of the blood, and the field-marshal Mollendorf; but Davoust, whose army contained about 36,000 men, had already a few hours before occupied the important pass of Kosen. The repeated attacks of the division of Schmettau, which met the enemy at Hassenhausen, and of general Blücher's cavalry, were repelled, the second division of the Prussian army not coming to their assistance, being retarded by the bad roads. The duke himself being wounded in the eye by a musket shot, and general Schmettau being mortally wounded, all unity of operations was lost. The king now committed the chief command to the field-marshal Mollendorf, who gave the orders for the retreat; but the first division, on their retreat, becoming entangled with the second, which was advancing, Davoust so improved the consequent confusion as to achieve a complete victory, which won him the title of *duke of Auerstädt*. General Kalkreuth protected, nevertheless, for some time, the retreat of the army along the road from Auerstadt to Weimar and Buttstadt. It was intended to renew the battle on the 15th, but on this day the king received information in Sommerda of Hohenlohe's defeat. As the communication of the army with Halle, where the reserves were stationed, was entirely cut off, and it was pursued every where by Napoleon's battalions, and reduced to confusion, it was obliged to separate into small corps, some of which, under Hohenlohe's command, reached Magdeburg, and the Elbe, October 26, by a circuitous route over the Harz mountains. The loss sustained by the Prussians, up to October 14, was above

50,000 men, killed, wounded, or prisoners. The Saxons lost, in the whole, twenty-three officers killed, 115 wounded, and more than 6000 men prisoners. The loss of the French, in killed and wounded, did not amount, according to their own accounts, to more than 4100. The loss of the Prussians, after the battle, was still greater; for, October 16, 14,000 Prussians, under Mollendorf, shut up in Erfurt, surrendered to Murat. The captive Saxons, however, were released on promise never to serve again against France; whereupon Napoleon caused the neutrality of the electorate to be proclaimed by the grand duke of Berg on the 17th, though peace was not concluded with Saxony till December 11, at Posen. By this measure, Napoleon secured his right flank, in case he should advance to Berlin, and opened to his own use all the resources of the electorate, which he occupied. The most important events now followed each other in rapid succession. October 18, Bernadotte attacked the Prussian reserves of 10,000 men, under Eugene, duke of Wurtemberg, at Halle, and made 5000 prisoners. Davoust marched by way of Leipsic and Wittenberg, Launes by way of Dessau, to Berlin (October 25), which Napoleon entered on the 27th. Spandau surrendered to Lannes, October 25. Meanwhile general Kalkreuth succeeded in conducting a part of the residue of the army, 12,000 in number, beyond the Oder. Blucher, on the contrary, did not join Hohenlohe with the wreck of the reserves, but, after the prince had capitulated at Prenzlau with 17,000 men, October 28, proceeded to Strelitz, where he formed a junction with the corps of the duke of Weimar, under the command of the duke of Brunswick Cels. His forces now amounted to 21,000 men; but, pursued by Murat, Bernadotte and Soult, he was obliged to press forward towards Lubeck on the 5th, and capitulate at Ratkau on the 7th. (See *Lubeck*.) Meanwhile a corps of cavalry of 6000 men, under general Schimmelpfennig, had surrendered, on the 29th, to general Milhaud, at Pasewalk; and on the 31st, another corps of 4000, under general Bila, at Anklam, surrendered to general Becker. Stunned by this annihilation of the Prussian army in the space of fourteen days, the commanders of fortresses surrendered their places to the enemy, without the honour of resistance. The last bulwark of the monarchy, Magdeburg, which was abundantly supplied with every necessary, general Kleist shamefully opened to the French under Ney, on the 8th of November. Napoleon, elated by his success, suddenly broke off the pacific negotiations, which were near a conclusion, carried his arms across the Oder, invited the Poles to his standard, and came up with the Russians on the Vistula. To all the military reasons for the victory of Napoleon, the great moral difference of the two armies must be added—the French, enthusiastic for glory and for their commander, led by excellent officers, mostly young; the Prussian army, consisting, in a great measure, of foreigners and rabble, ready to run away at the first good opportunity, their generals old, their king weak. Immense resources were opened to Napoleon by the possession of all North Germany, with the exception of Colberg; for he had taken possession of the electorate of Hesse, November 1; of Brunswick and Fulda, Oct. 26; of Hanover, November 9; of the Hanseatic cities, November 19; of Mecklenburg, November 28; and of Oldenburg, December 6. November 21, the celebrated decree of Berlin was issued, interdicting all commerce between Great Britain and the continent, and declaring the British islands in a state of blockade.

JENKINSON, CHARLES. See *Liverpool*, *Earl of*.  
JENKINSON, ROBERT BANKS. See *Liverpool*, *Earl of*.

JENNE, one of the most celebrated and important cities in Central Africa, was first visited by Caillé, the French traveller, in 1828. It is described by him as situated at the eastern extremity of a branch of the Niger, separating, below Sego, from the main current, with which, after passing the former city, it again unites. The country around, as far as the eye can reach, forms only a marshy plain, interspersed with a few clumps of trees and bushes. The city is two miles and a half in circuit, surrounded by a wall of earth; the houses tolerably well built of bricks dried in the sun; the streets so wide that seven or eight persons may walk abreast. Population is estimated by Caillé at 8,000 or 10,000. The inhabitants consist of various African tribes, attracted by the extensive commerce of which Jenne is the centre. The four principal tribes are the Foulas, Mandingoes, Bambaras and Moors, of whom the first are the most numerous, and are strict adherents to Mohammedanism, compelling the pagan Bambaras to conform to the rules of the Koran, whilst they are at Jenne. The trade is chiefly in the hands of thirty or forty Moorish merchants, who maintain a communication with Timbuctoo, in barks of considerable size, ranged along the river. The markets are filled with the productions of the surrounding country, either for consumption or exportation; in exchange for which, articles are brought from Timbuctoo, including a variety of European goods. Caillé found the merchants of Jenne more polished than any natives of Africa with whom he had had dealings. The mode of living is extremely simple. See Caillé's *Journey to Timbuctoo*.

JENNER, EDWARD; an English physician, celebrated for having introduced the practice of vaccination, as a preventive of the small-pox. He was the youngest son of a clergyman in Gloucestershire, and was born May 17, 1749. Being destined for the medical profession, he was, after a common school education, placed as an apprentice with a surgeon, at Sodbury, in his native county. He subsequently visited London, to finish his studies, by attending the lectures of the celebrated anatomist John Hunter. Returning to the country, he settled at Berkeley, to practise the various branches of his profession. He had already obtained the reputation of an ingenious practitioner, and a man of talent and science, when he made known to the world the important discovery which has raised him to an enviable situation among the benefactors of the human race. His investigations concerning the cow-pox were commenced about the year 1776, when his attention was excited by the circumstance of finding that some individuals, to whom he attempted to communicate the small-pox by inoculation, were not susceptible of the disease; and, on inquiry, he found that all such persons, though they had never had the small-pox, had undergone the casual cow-pox, a disease common among the farmers and dairy-servants in Gloucestershire, who had some idea of its preventive effect. Other medical men were aware of the prevalence of this opinion; but they treated it as a popular prejudice, and Jenner seems to have been the first who ascertained its correctness, and endeavoured to derive from it some practical advantage. He discovered that the *variole vaccinae*, as the complaint has been since termed, having, in the first instance, been produced by accidental or designed inoculation of the matter afforded by a peculiar disease affecting the udder of a cow, could be propagated from one human subject to another by inoculation, rendering all who passed through it secure from the small-pox. He made known his discovery to some medical friends, and in the month of July, 1796, Mr Cline, surgeon to St Thomas's hospital, introduced vaccination into the metropolitan

The practice of vaccine inoculation was adopted in the army and navy, and honours and rewards were conferred on the author of the discovery. The diploma constituting him doctor of medicine, was presented to Jenner as a tribute to his talents, by the university of Oxford. He was chosen a fellow of the Royal Society, and of other learned associations; and a parliamentary grant was made to him of the sum of £20,000. The extension of the benefits of vaccination to foreign countries, spread the fame of the discoverer, who received several congratulatory addresses from continental potentates. He died suddenly, in consequence of apoplexy, January 26, 1823, and was interred in the parish church of Berkeley. Doctor Jenner was the author of an Inquiry into the Causes and Effects of the Cow-pox, (1798, 4to); and Farther Observations on the *Variolæ Vaccinæ*, or Cow-pox, besides various letters and papers on the same subject, published in periodical works. See *Vaccination*.

JENNY, COTTON. See *Spinning*.

JENYNS, SOAME, a witty and elegant writer, was the only son of Sir Roger Jenyns, knight. He was born in London, in 1704, and received a domestic education until the age of seventeen, when he was entered a fellow commoner of St John's college, Cambridge. He remained three years at the university, and then married early a lady with a large fortune, to whom his father was guardian; but the marriage proved unhappy, and, in consequence of an elopement, a separation took place. In his youth, Mr Jenyns, with a small and delicate person, sustained the character of a beau, and his first performance was a poem on the Art of Dancing, published in 1728. In 1741, he was left, by the death of his father, master of a large fortune, on which he entered into public life as representative of the county of Cambridge. He began his career by supporting Sir Robert Walpole, and ever after remained a faithful adherent to the minister for the time being. In 1757, he published his *Free Inquiry into the Nature and Origin of Evil*, the fundamental principle of which is, that the production of good without evil is impossible; that evils spring from necessity, and could not be done away without the sacrifice of some superior good, or the admission of greater disorder. In respect to moral evil, his theory is, that it is permitted, in order to provide objects for the just infliction of physical evils. In 1776, appeared his *View of the Internal Evidences of the Christian Religion*. The foundation of his reasoning is, that the Christian religion is a system of ethics so superior to, and unlike any thing which had previously entered into the mind of man, that it must necessarily be divine. In 1782, appeared his *Disquisitions on Various Subjects* (8vo.), which are marked with his usual characteristics of sprightly wit and shrewd observation, but are vague and declamatory. He died in 1787. His works have been collected into four volumes (12mo), with a life prefixed by C. N. Cole.

JEPHTHAH; a natural son of Gilead, who, being driven from home by his brothers, lived in the land of Tob, but, when the Ammonites waged war against Israel, was sent for to defend his countrymen. Jephthah tried conciliatory measures, but being unsuccessful in this, he put himself at the head of the Israelites, and defeated the enemy. Having rashly made a vow that, if he was victorious, he would sacrifice to God, as a burnt-offering, whatever should first come to meet him from his house, he was met, on his return, by his daughter, his only child, whom he sacrificed, in consequence, to the Lord. (*Judges*, xi. 29, 40.) The mode in which the sacrifice was performed, has given rise to much controversy, some authors maintaining that Jephthah put her to death near the altar; others that he devoted her to perpetual virginity in

the temple; others, and most commentators, think that he actually sacrificed her as a burnt-offering, and, though Moses prohibits, explicitly, such a sacrifice, that it may have been permitted in the wild and barbarous times of Jephthah. Jephthah ruled six years as a judge and general. (*Judges* xi. and xii.)

JERBOA (*dipus*, Gmel.) These singular little animals are found in many parts of the old continent, but seldom in great plenty. The most common species is the *D. sagitta*. It is of a pale yellowish fawn-colour on the upper parts, and white beneath; the length of the body is about eight inches, and of the tail ten. The jerboas inhabit dry, hard, and clayey ground, in which they make their burrows. These are of considerable length, and run oblique and winding; at about half a yard below the surface of the ground, they terminate in large excavations or nests; they are usually provided with but one opening, though the animals are provident enough to make another passage, to within a short distance from the surface, through which they rapidly penetrate in case of necessity. It is almost impossible to kill them, except by coming on them unawares. The Arabs, however, take them alive, by stopping up all the outlets of the different galleries belonging to the colony, with the exception of one, through which they force them out. They keep within their holes during the day, sleeping rolled up, with their head between their thighs. At sunset they come out, and remain abroad till morning. They go on their hind legs only, the fore legs being very short; their motion is, nevertheless, very rapid, being effected by leaps of six or seven feet, which they repeat so swiftly, that it is nearly impossible to overtake them. They do not proceed in a straight line, but spring first to one side, and then to the other. In leaping, they carry their tails stretched out, whilst, in standing or walking, they carry them in the form of an S, the lower curve touching the ground. In their wild state, these animals are very fond of bulbous roots; but, when confined, they will feed on raw meat. They are tamed without much difficulty, but they require to be kept warm. The jerboa is supposed to be the *cony* of the Bible. It was forbidden food to the Israelites; it is, however, eaten by the Arabs.

JEREMIAH, the second of the great prophets of the Old Testament, of a noble Jewish family of the priestly order, flourished during the darkest period of the kingdom of Judah, under the last four kings, till the Babylonish captivity, and exercised the prophetic office for forty years, with unwearied patience and fidelity. But in vain did he exhaust admonitions, entreaties, and warnings to move the people to a sense of piety and resignation; he was rewarded by abuse, imprisonment, and menaces of death. After the destruction of Jerusalem, when all the people were carried into captivity, he was honoured by Nebuchadnezzar as the noblest of his nation, and permitted to choose his own place of residence. The old prophet staid by the ruins of the holy city, and continued to direct the remaining Jews by his counsels till their flight into Egypt, where he died at an advanced age. He began, under the reign of Jehoia-kim, to dictate his instructions and prophecies to his amanuensis Baruch. They evince the most ardent patriotism and unshaken trust in the God of his fathers, but, at the same time, show how much the spirit of the prophet was crushed by his own misfortunes and the disasters of his country. It is only in his predictions against foreign states, that his expression rises to some degree of strength, but elsewhere his tone is as mild as his character, and mournful as the times in which he lived. He clearly foresaw the downfall of Judah, and lamented it on the ruins of Jerusalem. His Lamentations, the fruit of this grief

for the fate of his country, are elegies full of touching melancholy and pious resignation, which, by their beautiful, harmonious structure, remind us of a better era of Hebrew poetry.

JERICHO ; a considerable town of ancient Judea, on a plain north-east of Jerusalem, on the west of Jordan, noted, especially in Solomon's time, for its balsam-gardens, and its thickets of palm-trees and roses, and carrying on a flourishing trade in balsam and spices. It was the key of Palestine, and was therefore invested by the Israelites, who had passed the Jordan under Joshua to conquer this country. On the seventh day it was taken in a miraculous manner, and destroyed, but was rebuilt some time after. Its site is now occupied by the village of Raha. The gardens and thickets have disappeared; the balsam-tree alone is cultivated. There is a creeping plant, with a singularly shaped and fragrant flower, which we call the *rose of Jericho* (*anastatica*). It was probably brought over to Europe in the times of the crusades.

JERMACK. See *Siberia*.

JERMOLOFF (not *Yermoloff*), ALEXEI PETROWITCH ; Russian general of infantry, governor of the provinces of Georgia and Caucasus, and general in chief of the army of the Caucasus. In April, 1815, Jermoloff commanded the second corps of the Russian army, which, under Barclay de Tolly, marched from Poland into France. In 1817, he was sent, with 50,000 select troops, to occupy the frontiers on the side of Persia. Having personally inspected all the military posts, he was sent as ambassador to the Persian court at Teheran, where the Russian cabinet wished to counteract the influence of the British. For this reason, the suite of Jermoloff was very splendid. He had with him the flower of the Russian nobility, and, besides, some French officers, whom Napoleon had sent with Gardanne on a similar mission to Persia in 1807. Jermoloff also received the reports made by Gardanne, and the maps drawn by the French officers. A very advantageous treaty of commerce and amity was soon concluded between Russia and Persia, by which the peace of Tiflis, September 13, 1814, was confirmed. Russia was intrusted by the same compact, in some degree, with the guarantee of the Persian succession, and Persia was placed almost in the same relation to Russia, as Poland had been in the time of Catharine II. Jermoloff then returned to his former station, and exerted himself much for the improvement of commerce in those parts. In 1819, he sent captain Muravjeff to the coast of the Caspian sea, to invite the Turkmenians living there to form amicable connexions with Russia. Under him, the army of the Caucasus was increased to 100,000 men. In 1827, he subdued the Tsbetchenises mountaineers, addicted to robbery. In 1826, he repulsed the Persians, who, under Abbas Mirza, had broken the peace of Ghulistan. In April, 1827, general Paskewitch succeeded him in the chief command against the Persians.

JEROME, Sr, one of the most learned and prolific authors of the early Latin church, was born about 331, in Dalmatia, of wealthy parents, educated with care in literary studies, and made familiar with the Roman and Greek classics, under the grammarian Donatus at Rome. But he did not escape uncontaminated by the licentiousness of the capital; and he himself confesses the excesses of his youth. He soon, however, became inclined to the Christian faith. The catacombs and tombs of the martyrs first excited his devotion. His travels on the Rhine and in Gaul, made him acquainted with several Christian preachers, and before his fortieth year he was baptized in Rome. After a long residence at Aquileia, he went, in 373, to Antioch, in Syria, where his in-

clination to an ascetic life became more decided. In 374, he retired to the deserts of Chalcis, and there passed four years as a hermit, in the severest mortifications and laborious studies. He left his solitude again to be ordained presbyter at Antioch. He did not, however, confine himself to the discharge of the duties of this office, but soon after went to Constantinople, to enjoy the instruction of Gregory of Nazianzen. In Rome, whither he accompanied his friend the bishop Damasus, he made his appearance as a teacher. His exposition of the Holy Scriptures found favour with the Roman ladies; and, although no one reprehended more than he the manners of the fashionable world, several matrons of distinction, with their daughters, complied with his exhortations and became nuns. St Marcella and St Paula are celebrated for the learned and ingenious theological epistles he wrote them, and for their rare monastic piety. Paula accompanied him to Palestine, in 384, where he founded a convent at Bethlehem, with her funds, and in her society; in this he remained till his death, in 420. His writings show his active participation in the controversies concerning the doctrines of Origen, Meletus and Pelagius; he always defended, with seal and ability, the orthodox doctrines of the church, though his own writings are not free from the vestiges of the views and opinions of these different parties. His profound knowledge of the Bible, which he read in the original language, frequently led him to results on which he subsequently had controversies with the church; and his method of interpreting the Scriptures borders closely on the allegorical interpretations of Origen, whom he respected, studied, and attacked. His biblical labours are highly valuable; his Latin version of the Old Testament, from the original language, is the foundation of the Vulgate, and his commentary gave a new impulse to the study of the Holy Scriptures. In the controversy with Jovinian and Vigilantius, the opponents of the ascetic bigotry, his immoderate zeal for the monastic life, which contributed much towards the promotion of this new institution, led him to expressions which manifest more strength and fire of feeling than maturity of judgment. On the whole, with a glowing imagination, which made his style lively and attractive, and with an extensive knowledge of languages, he possessed a less philosophical genius than his more celebrated contemporary Augustine.

JEROME OF PRAGUE; of the family of Fastfisch, educated at the universities of Prague, Paris, Cologne, and Heidelberg; in faith and suffering, the companion of the famous John Huss, whom he excelled in learning and eloquence, and to whom, in the bold attempt at reformation of the fifteenth century, he was inferior only in moderation and prudence. His reputation for learning was so great, that he was employed by Ladislaus II. of Poland, to organise the university of Cracow; and Sigismund of Hungary caused Jerome to preach before him at Buda. The doctrines of Wickliff, which he introduced into his preaching, subjected him to a short imprisonment by the university of Vienna; but he was released by the people of Prague. He now took a zealous part, at Prague, in the contest of his friend Huss against the abuses of the hierarchy, and the dissoluteness of the clergy, and not unfrequently proceeded to violence. He attacked the worship of relics with ardour, trampled them under foot, and caused the monks, who opposed him, to be arrested, and even had one thrown into the Moldau. He publicly burned, in 1411, the bull of the crusade against Ladislaus of Naples, and the papal indulgences. When Huss was imprisoned in Constance, he could not remain inactive and hastened to his defence. But a public letter, in which he requested a safe con-

dict from the council of Überlingen, was not satisfactorily answered, and, on his attempting to return to Prague, the duke of Sulzbach caused him to be arrested in Hirschau, and carried in chains to Constance. He here received, in prison, information of the terrible fate of his friend, and, after several hearings, in which no one was able to oppose him, an imprisonment of half a year had so worn him down, that he finally yielded to violence, and, on the 11th Sept., 1415, consented to recant the heresies with which he and Huss were charged. But this apostasy did not deliver him, and, after languishing a year, without being able to see or read, in the darkness of the dungeon, he displayed his former courage, on an audience on the 26th May, 1416. He solemnly retracted his recantation, avowed that none of his sins tormented him more than his apostasy, and vindicated the principles of Huss and Wickliff, with a boldness, energy and eloquence, that extorted the admiration of his adversaries, but, nevertheless, precipitated his destruction. May 30, he was burned at the command of the council. He proceeded to the pile, consoled by singing the apostles' creed and spiritual hymns, and gave up his spirit in prayer. His ashes were thrown into the Rhine, in order to annihilate his memory; but posterity has done him justice, and reveres him as the martyr of truth, who, unwearied in life, and noble in death, has acquired an immortal renown for his share in the reformation. His views and doctrines coincided closely with those of Huss. See *Huss*.

JERSEY, *NEW*. See *New Jersey*.

JERSEY, ISLE OF; a thriving and very populous island in the English channel, the largest and most southerly of that group on the coast of France, which forms an appendage to the British crown. Its figure is nearly an oblong square, stretching, in an easterly direction, twelve miles, with a breadth no where greater than seven, and at a medium five miles. It contains about 40,000 acres, twelve parishes, two towns—St Helier, the capital, and St Aubin—and several villages and fortresses. Its coast is surrounded by a natural barrier of rocks, which nearly encircle the whole island. The climate is exceedingly mild, the soil fertile, and the situation well adapted to commerce. The inhabitants speak the French language, though it is now on the decline. They make their own laws; are exempt from naval and military service, and from the dominion of the English church; have the benefit of a free port, and trade with the enemies of Britain, even in time of war; above all, they are free from the taxes with which the mother country is loaded. They are almost wholly occupied in agriculture and commerce. The land is sufficiently adapted for all the common crops, and also for the pasture of cattle, which is practised to some extent; but the singular mildness of the climate has decided the inhabitants to apply chiefly to the produce of the orchard, and to trust, in a great measure, to their trade for a supply of grain, at least for one third of their consumption. The fruits, therefore, are of the highest flavour; and great quantities of cider, the common beverage, are made annually. Various fortresses have been erected, viz. Elizabeth castle, mount Orgueil, fort Henry, La Rocque, and several others. The coast is also defended by a chain of martello towers, and by numerous redoubts and batteries. The government consists of a court of judicature, and an ecclesiastical body acting separately, and, at the same time, uniting with twelve nobles and a military governor, to form the assembly of the states, the legislative body of the island, without whose approbation no law made in Britain is binding. The governor is appointed by the crown, convokes the assembly, and has a nega-

tive voice, which, however, is merely nominal, except where the interest of the crown is concerned. The court of judicature consists of a bailiff and a president, chosen by the crown, twelve jurats, chosen by the householders, and various officers; the clerical court, of a dean and eleven rectors. Remains of antiquities, principally druidical, are found in different parts of the island. The architecture of all the churches is the pointed or Gothic. Various attempts have been made by the French to possess themselves of the island, but without success; the most remarkable was in 1781. Population, 36,580; seventy-five miles from Weymouth, the nearest shore of England; and from Carteret and Boil, the nearest of the French ports, seventeen. Lon. of St Aubin, 2° 11' W.; lat. 49° 13' N.

JERUSALEM (Heb. *Salem*; hence the Greek *Hierosolyma*, the sacred *Solyma*, and the Turkish *Soliman*). This celebrated city of Palestine is subject to the pacha of Damascus. Its environs are barren and mountainous. The city lies on the western declivity of a hill of basalt, surrounded with rocks and deep valleys, with a much colder climate than one would expect from its geographical situation. It is now only about two miles in circuit. The town is built irregularly, has pretty high walls, and six gates, which still bear Hebrew names. The houses are of sandstone, three stories high, and without windows in the lower story. This lifeless uniformity is only diversified, here and there, by the spires of the mosques, the towers of the churches, and a few cypresses. Of 25,000 inhabitants, 13,000 are Mohammedans, and 4000 Jews. Christians and Jews wear a blue turban to distinguish them. The women, in their close veils and white dress, look like walking corpses. The streets are unpaved, and filled either with clouds of dust or with mire. Nothing is to be seen but veiled figures in white, insolent Turks, and stupid or melancholy Christians. That Jerusalem is no place for the cultivation of the arts or sciences one may easily conjecture, from the despotism of the Turks, and the gloomy superstition of the Christians. Weavers and slipper-makers are the only artisans. A multitude of relics, which are, probably, not all manufactured in the city, but are sent in also from the neighbourhood, are sold to the credulous pilgrims. Nevertheless, this city forms a central point of trade to the Arabians in Syria, Arabia and Egypt. The people export oil, and import rice by the way of Acre. The necessaries of life are in profusion, and quite cheap, the game excellent, and the wine very good. The pilgrims are always a chief source of support to the inhabitants; at Easter, they often amount to 5000. But few of them are Europeans. Jerusalem has a governor, a cadi or supreme judge, a commander of the citadel, and a mufti to preside over religious matters. There are still many places and buildings in the city designated by ancient sacred names. The citadel, which is pretended to have been David's castle, is a Gothic building throughout. It is also called the *Pisan tower*, probably because it was built by the Pisans during the crusades. All the pilgrims go to the Franciscan monastery of the Holy Saviour, where they are maintained a month gratuitously. Besides this, there are sixty-one Christian convents in Jerusalem, of which the Armenian is the largest. They are supported by benevolent contributions, principally from Europe. The church of the Holy Sepulchre has been for 1500 years the most sacred place in Jerusalem. It is composed of several churches united, and is said to be erected on Golgotha. Here is shown, in a large subterranean apartment richly ornamented, the pretended grave of the Saviour, with a sarcophagus of white marble. The empress Helena is reported to have founded this

church in the fourth century, after she had found the true cross. The Jews live in great wretchedness, and are confined to a small part of the city. The temple of the Mohammedans, which is regarded as one of their greatest sanctuaries, is magnificent. No Jew or Christian is permitted to enter the inner sanctuary. This temple consists of two large buildings, of which the one, El Aksa, is adorned with a splendid dome and beautiful gilding. The other edifice is octangular, and is called *El Sahara*. Here the Mohammedans show the footsteps of their prophet surrounded with a golden grate; and a Koran, which is four feet long, and two and a half broad. On the mount of Olives is to be seen a Christian church, in which is shown a foot-print of the Saviour, which he left on the place, when he ascended to heaven. Besides many old Jewish monuments, there are a great many Greek and Roman, several Christian, and, especially, Gothic monuments, which originated in the times of the crusades.

A contemporary of Abraham, Melchisedec, is called *king of Salem*, 2000 years before Christ: this Salem is supposed to be the Jerusalem of after times. This town then came into the possession of the Jebusites, and when the Israelites conquered the land of promise (B. C. 1500), it was assigned, in the division of the country, to the tribe of Benjamin. The Jebusites, however, appear afterwards to have recovered possession of the place; for David conquered the city, called it after his name, and built the castle of Zion. His son Solomon greatly embellished the city, and caused the temple to be built by the skilful artists of Tyre. Under his successors, Jerusalem was the capital of the kingdom of Judah. Five times it was taken and plundered; first under Rehoboam by the Egyptians, then under Joram by the Arabians, under Joash by the Syrians, under Amaziah by the Israelites, and under Josiah by the Egyptians again (B. C. 611). Herodotus also mentions the last conquest of it, calling the city *Kadytas*, which resembles *Kedushah*, the Holy, and the Mohammedans still call the city *El Koda*. At last, the Chaldean king, Nebuchadnezzar, during the reign of Zedekiah, conquered the kingdom, razed the city to the ground (B. C. 586), and carried the Jews to Babylon. Seventy years after, Cyrus gave them permission to return and rebuild the city and temple. This was done under the direction of their high priests, Ezra and Nehemiah, whose successors governed them a long time. The story of Alexander's making a pacific visit to Jerusalem, after his conquest of Tyre, is nothing but a Jewish invention, as Josephus is the only author who mentions it. Alexander's successor, Ptolemy, the son of Lagus, captured Jerusalem, and carried a great number of the better sort of Jews to Alexandria. It then remained, for a long time after it was taken by Antiochus the Great, under the jurisdiction of the Syrian kings. Under the Maccabees, the Jews were again free for a considerable time, and chose their own rulers. One of the last of these, Aristobulus, invited Pompey the Great into the country, and thus Jerusalem came under the Roman dominion (B. C. 64). But, as it continued to have its own kings, at least in name, and also high priests, together with the Roman governors, this occasioned constant troubles, which were finally ended by the destruction of the city, and extermination of the inhabitants, by Vespasian and Titus, after a bloody siege (A. D. 70). Some buildings, however, were left among the ruins. The Jews again collected together, built on the place, and again rebelled against the Romans. Provoked by this obstinacy, the emperor Adrian, at last, in the year 118, ordered all that Titus had spared to be destroyed. He commanded a new city to be built in its place, called *Ælia Capitolina*, in which no Jew was per-

mitted to dwell. Constantine the Great, and his mother Helena, from pious motives, ordered all the heathen monuments to be destroyed, and erected many new Christian edifices. Julian conceived the idea of rebuilding the old temple of the Jews, but was said to have been hindered from executing his plan by the eruption of subterranean fire. The city remained under the government of the Eastern emperors till Chosroes, king of Persia, conquered it in the year 614. It was recovered, however, by the emperor Heraclius, in the peace of 628. This prince prohibited the Jews from dwelling there, and so alienated the patriarch of Jerusalem, Sophronius, by sectarian differences, that the Saracen caliph Omar found little difficulty in making himself master of the city (A. D. 637). From the Saracens it passed into the hands of the Turks. In the first crusade, Godfrey of Bouillon took Jerusalem. It was erected into a Christian kingdom, to which the Turks put an end in 1187. Clarke, Chateaubriand &c., describe its present state.

JERUSALEM. JOHN FREDERIC WILLIAM, was born November 22, 1709, at Osnaburg, where his father was a clergyman, and early displayed great talent. As early as 1724, he entered the university of Leipsic, where he studied theology. He then studied at Leyden, went with two young noblemen to the university of Gottingen, visited London, and was, in 1742, appointed, by the duke of Brunswick, court preacher and tutor of the hereditary prince. The *Collegium Carolinum*, afterwards so famous, was established on a plan suggested by him. In 1752, he was made abbot of the convent of Niddagshausen, near Brunswick. The chancellorship of the university of Gottingen was offered to him, but he would not leave Brunswick, where his benevolent activity found full exercise. In his old age, his son destroyed himself in consequence of an unfortunate passion for a married lady. This gave rise to Goethe's *Sorrow of the young Werther*. The father died in 1792, esteemed by all Germany as a theologian, and for the purity and beneficence of his character. His sermons (Brunswick, 1788—1789, 2 vols.) are read, as are also his *Contemplations on the most important Truths of Religion* (1785 and 1796, 2 vols.) He wrote many other works, and is considered one of the best men of his time in Germany.

JESO, or JEDSO, or YEDSO, or JESSO, or MATSMAI; a large island in the North Pacific ocean, governed by a prince tributary to the emperor of Japan. The inhabitants are more rude and savage than the Japanese. They live chiefly on fish and game. Lon. 140° 10' to 147° 10' E.; lat. 42° to 45° N. Square miles, 53,000. Chief town, Matsma.

JESSE; a man of Bethlehem, who lived by raising cattle; the father of eight sons, of whom David was one. When Saul persecuted the latter, Jesse fled into the land of the Moabites, where he seems to have died, as no mention is made of him after David's accession to the throne.

JESTER, or COURT FOOL. In the middle ages, every court, secular or ecclesiastical, had its fool, as a necessary appendage; and there are some instances of court jesters in the eighteenth century. Tasso, in his *Illustrations of Shakspeare*, has a dissertation on the fools and clowns. He states that Mucko John was the last person who regularly held the office of court jester in England, his predecessor, Archy Armstrong, having been sentenced to have his coat pulled over his head, and to be dismissed the king's service, for a sarcasm on Laud (1637). Since the time of the commonwealth, the post of king's fool has been discontinued, though some private persons had fools late in the last century. Swift wrote an epitaph on Dicky Pearce, the earl of Suffolk's fool.

(1728). Mr Douce states that the costume of the domestic fool, in the time of Shakspeare, was of two sorts. The one was a motley or party-coloured coat, attached to the body by a girdle, and often having bells on the skirts and elbows. The breeches and hose were of one, and sometimes the legs were of different colours. A hood resembling a monk's cowl, covered the head completely, and the breast and shoulders partly. It sometimes bore ass's ears, sometimes the neck and head of a cock, and sometimes only the comb of that bird (whence *coarcomb*, as a term of contempt). The bawble (*marotte*) was a short stick, terminated with a fool's head, or with that of a doll or puppet. To this was frequently appended a blown bladder, sometimes filled with sand or peas, and employed as a weapon of sportive offence; sometimes a skin or bladder only, and sometimes a club instead of a bawble, and, occasionally, both together. The other dress, which seems to have been most common in the time of Shakspeare, was a long petticoat, of various colours, fringed with yellow. There were, however, many variations from this dress; bells supplied the place of the cock's comb; the head was shaven like a monk's crown; fox tails or squirrel tails were fastened on the clothes, &c. See *Fools, Feast of*.

JESUITS, or SOCIETY OF JESUS; a religious order, which rose in influence and power far above all the other orders, though strictly prohibiting its members to accept any office in the church, and which, in the art of ruling, excelled the governments of the world no less than its ecclesiastical rivals. No other religious order affords a parallel to this; for, while those who give themselves only to devotion and religious contemplation, present few distinguishing traits, and, for the most part, differ from one another only in their names, in the fashion and colour of their dress, the greater or less strictness of their rules, the number of their penances and devotional exercises; and while those of the more active class, who operate abroad by their influence at courts and in families, and by engaging in offices of instruction, pastoral care, or charity, are almost universally but monks, the society of Jesus early raised itself to a degree of historical importance unparalleled in its kind. But a small part of this greatness is to be ascribed to their founder, Ignatius Loyola (q. v.), who owes his fame more to the shrewd policy and energy of his successors than to the merit of the original scheme of the order. At the university of Paris, Loyola entered into an agreement with some of his fellow students to undertake the conversion of unbelievers, and a pilgrimage to Jerusalem. Pierre le Fevre (a Savoyard), Francis Xavier (a native of Navarre), James Lainez and Nicholas Bobadilla (two Spaniards of ardent and powerful minds), and Rodriguez, a Portuguese nobleman, were the first companions of Loyola. A war with the Turks prevented their journey to Jerusalem. They therefore went to different universities in Upper Italy, to gain new associates; Loyola himself went with Le Fevre and Lainez to Rome, where he accomplished, in 1539, his plan of founding a new and peculiarly organized order. He called it the *society of Jesus*, in consequence of a vision, and bound the members, in addition to the usual vows of poverty, chastity, and implicit obedience to their superiors, to a fourth, viz. to go, unhesitatingly, and without recompense, whithersoever the pope should send them, as missionaries for the conversion of infidels and heretics, or for the service of the church in any other way, and to devote all their powers and means to the accomplishment of the work. The novices, besides spiritual exercises, were to be proved by performing the most menial offices for the sick, Xavier having given the example by sucking the loathsome sores of

the sick in the hospitals. A special bull of Paul III. in 1540, established this society, whose object appeared so favourable to the interests of the papal power; and in the following year, the members, assembled in Rome, chose their founder for their first general. He showed himself, however, unequal to the management of great affairs. As general, he was ever pursuing secondary objects, while his learned and more sagacious friends, especially Lainez, who was his constant companion, contrived to improve and carry out his rude plans for the advancement of the society. The popes Paul III. and Julius III., seeing what a support they would have in the Jesuits against the reformation, which was rapidly gaining ground, granted to them privileges such as no body of men, in church or state, had ever before obtained. They were permitted not only to enjoy all the rights of the mendicant and secular orders, and to be exempt from all episcopal and civil jurisdiction and taxes, so that they acknowledged no authority but that of the pope and the superiors of their order, and were permitted to exercise every priestly function, parochial rights notwithstanding, among all classes of men, even during an interdict,—but also (what is not even permitted to the archbishops unconditionally), they could absolve from all sins and ecclesiastical penalties, change the objects of the vows of the laity, acquire churches and estates without further papal sanction, erect houses for the order, and might, according to circumstances, dispense themselves from the observance of canonical hours of fasts and prohibition of meats, and even from the use of the breviary. Besides this, their general was invested with unlimited power over the members; could send them on missions of every kind, even amongst excommunicated heretics; could appoint them professors of theology at his discretion, wherever he chose, and confer academical dignities, which were to be reckoned equal to those given by universities. These privileges, which secured to the Jesuits a spiritual power almost equal to that of the pope himself, together with a greater immunity, in point of religious observance, than the laity possessed, were granted them to aid their missionary labours, so that they might accommodate themselves to any profession or mode of life, among heretics and infidels, and be able, wherever they found admission, to organize Catholic churches without a further authority. But the latitude in which they understood their rights and immunities gave occasion to fear an unlimited extension and exercise of them, dangerous to all existing authority, civil and ecclesiastical, as the constitution of the order, and its erection into an independent monarchy in the bosom of other governments, assumed a more fixed character. A general dispersion of the members throughout society, with the most entire union and subordination, formed the bases of their constitution. The society of Jesus was accordingly divided into several ranks or classes. The novices, who were chosen from the most talented and well educated youths and men, without regard to birth and external circumstances, and were tried, for two years, in separate novitiate-houses, in all imaginable exercises of self-denial and obedience, to determine whether they would be useful to the purposes of the order, were not ranked among the actual members, the lowest of whom are the *secular coadjutors*, who take no monastic vows, and may therefore be dismissed. They serve the order partly as subalterns, partly as confederates, and may be regarded as the people of the Jesuit state. Distinguished laymen, public officers, and other influential personages (e. g. Louis XIV. in his old age), were sometimes honoured with admission into this class, to promote the interests of

the order. Higher in rank stand the *scholars* and *spiritual coadjutors*, who are instructed in the higher branches of learning, take upon them solemn monastic vows, and are bound to devote themselves particularly to the education of youth. These are, as it were, the artists of the Jesuit community, are employed as professors in academies, as preachers in cities and at courts, as rectors and professors in colleges, as tutors and spiritual guides in families which they wish to gain or to watch, and as assistants in the missions. Finally, the nobility, or highest class, is made up of the *professed*, amongst whom are admitted only the most experienced members, whose address, energy, and fidelity to the order have been eminently tried and proved. They make profession, i. e. take the vows of their order, by binding themselves, in addition to the common monastic vows, by a fourth vow, to the undertaking of missions; and, when they are not living together in pious ease in their professed houses, they serve as missionaries among heathens and heretics, as governors of colonies in remote parts of the world, as father-confessors of princes, and as residents of the order in places where it has no college. They are entirely exempt, on the other hand, from the care of the education of youth. None but the professed have a voice in the election of a general, who must himself be of their number, and who has the right of choosing from them the assistants, provincials, superiors, and rectors. The general holds his office for life, and has his residence in Rome, where he is attended by a monitor and five assistants or counsellors, who also represent the five chief nations,—the Italians, Germans, French, Spanish, and Portuguese. He is the centre of the government of the whole order, and receives monthly reports from the provincials, and one every quarter from the superiors of the professed-houses, from the rectors of the colleges (which are the monasteries of the order, but with nothing very monastic about them), and from the masters of the novitiates. These reports detail all remarkable occurrences, political events, and the characters, capacities, and services of individual members, and thereupon the general directs what is to be done, and how to make use of tried and approved members. All are bound to obey him implicitly, and even contrary to their own convictions. There is no appeal from his orders. He may even alter particular rules of the society, expel members without trial, or exile them by sending them away to some distant place, and inflict or remit punishments at his pleasure. Ignatius Loyola, who died July 31, 1556, at Rome, left to the order the sketch of this constitution, and a mystical treatise called *Exercitia Spiritualia* (Spiritual Exercises), the use of which was formally introduced among the Jesuits, and occupies the first four weeks of every novice. This pious enthusiast, but by no means great man, obtained a lasting fame, and the honour of canonisation (1622), by the rapid increase of his order, which, as early as 1556, numbered 1000 members in twelve provinces. The first was Portugal, where Naver and Rodriguez, at the invitation of the king, had founded colleges. The increase of the Jesuits was no less rapid in the Italian states, where they were supported by the influence of the pope; in Spain, where they were, at first, opposed by the bishops, but soon prevailed through the example of the nobility, especially of one of the most powerful grandees, Francis Borgia, duke of Candia, who became an *Inquist* (as the Jesuits were called in Spain, after their founder, Inigo); and in Catholic Germany, where Austria and Bavaria granted them privileges and foundations. At the universities of Vienna, Prague, and Ingolstadt, they obtained an

ascendency which they held for two centuries. In their strict hierarchical principles, in their restless, zealous activity, and in their success in making converts, the Catholic princes, as well as the pope himself, found the most effectual barrier against the growing power of Protestantism. Even to the common people they soon recommended themselves, as the offspring of the new spirit of the times, and were, therefore, readily favoured by persons who were ill-disposed to the monks. For institutions which would not adopt the tendency of the age towards practical improvement and a more cheerful tone of conduct, could no longer succeed, after the restoration of learning and sound reasoning; the excited world preferred business to contemplation, and the mendicant monks, who had every where pushed themselves into notice, had passed their most splendid epoch. Those who disliked the Franciscans as too coarse and vulgar, and the Dominicans as too rigid and gloomy, were the better pleased with the polished, cheerful, and social Jesuits. Nobody could accuse them of idle brooding in prayer and psalm-singing: even in the houses of the professed, the canonical hours were not observed; they nowhere remained long at their exercises of devotion, even as the spiritual guides of the laity; they carefully avoided all appearance of spiritual pride, and dressed like the secular clergy, and might even change this dress for the ordinary garb of the country, in places where they thought to gain easier entrance without any such mark of distinction. Besides this, they were directed to use a gentle demeanour while engaged in their religious or political operations; to win men by compliance with their peculiarities; never to contend openly, even against declared enemies; and never to betray any passion; but to keep their views and measures secret, and, under a show of calmness and reserve, to prosecute the more ardently and constantly, in secret, what might have excited opposition if made public. This spirit of worldly policy, and accommodation to circumstances, was principally derived from the artful principles of their second general, James Laines, who had the address to soften what was austere and monastic in the regulations of the founder, and to adapt them, according to the circumstances of the times, to the objects of the society. This was originally nothing else but the preservation and establishment of the papal power against all the attacks of Protestantism, of kings, and national bishops. To this end the Jesuits systematically laboured, under the pretext of promoting religion or the honour of God (*In nomine Dei gloriam*, as the inscription is on their arms), and, as nothing appeared more conducive to this purpose than the subjection of the mind and of public opinion, they gained dominion over the young by the establishment of schools, and over the adult by confession, preaching, and the common intercourse of society. When Laines died, in 1564, this system and the active, energetic spirit belonging to it, had already become decidedly fixed in the internal character of the order, so that the example of monastic devotion held up by his successor, Francis Borgia, who was afterwards canonized, and the efforts of popes Paul IV. and Pius V. to restore the observance of the canonical hours, proved ineffectual. The succeeding popes and generals allowed the order perfect freedom from all monastic constraint, and its wisdom of its system soon appeared evident in its important successes and services which it accomplished. Their foreign missions, begun by Francis Xavier, in the Portuguese East Indies, in 1541, were attended with vast and unprecedented success, their own accounts may be trusted. He conversed with the aid of his fellow missionaries who were men

to assist him, some hundred thousands to Christianity in Goa, Travancore, Cochín, Malacca, Ceylon, and even in Japan, and died (1551) on his way to China, with the fame of a true martyr for religion, which gained for him the name of the *apostle of India*, and the honour of canonization. His triumphs over heathenism were confirmed by the cruelties of the inquisition at Goa, while other Jesuits went to South America, and laboured successfully in the civilisation and subjugation of the natives in Brazil, and in the neighbouring country of Paraguay. Africa alone resisted their efforts; on the western coasts they never gained a settlement, and from the east they were driven by the Copts; while the Abyssinians, whom they had governed for a long time with the aid of Portugal, rose against them, and put them to death. But in Europe, their influence rapidly increased. Their efforts were chiefly instrumental in removing the impressions, so dangerous to the Catholic church, which the reformation had left even in Catholic countries. They carried out upon a grand scale, and for the higher classes, the improvements in the system of instruction, which had been already begun by the Barnabites, the fathers of the Christian doctrine, those of Somasquato and of the oratory, and, finally, by the Piarists, for the humbler classes of the community. Claudius Aquaviva, of the family of the dukes of Atri, general of the Jesuits from 1581 to 1615, was the author of their system of education, and his work, *Ratio et Institutio Studiorum Societatis Jesu*, is the platform of the far-famed schools of the Jesuits. These were partly boarding-schools for boys of all classes, and partly seminaries for those youths who were intended for the order, in which they staid till their entrance upon their novitiate. The scholars (so called) and conditors, living together in the colleges, gave instruction by methods well suited to the wants of the young, and accompanied with surprising success, so as to be considered as worthy of imitation even in the eighteenth century. A free, affable and affectionate manner towards the pupils, united with unceasing vigilance and a wise solicitude for the preservation of their innocence and virtue, distinguished these above all other monastic schools. Love and confidence prevailed in them. To excite emulation, and to animate industry, they had public exercises in speaking, and distributed prizes and titles of distinction. To strengthen and develop the body, gymnastic exercises were introduced, and even the outward demeanour and address were polished by theatrical representations. It is true that these last, which were intended to allure the public, and the miserable Latin which the pupils were often obliged to speak in the plays, were not the bright side of the Jesuit schools. The want of deep critical learning, and the arbitrary mutilation of the old classics for the use of the young, exposed the Jesuit teachers to the censure of the philologists. Nevertheless, the schools had an uncommon success, as the best of that time. A single college frequently had several hundred scholars; the young nobility were almost exclusively sent to them, and even from Protestant countries, so that the Protestants found it necessary to establish lycæums and academies for the gentry, of a character suited to the higher demands of the age. The Jesuits derived the greatest advantage from these institutions, by being enabled to choose the brightest geniuses at an early age, and mould them to their purposes. This explains how the society of Jesus was able to render important services to the cause of literature and science. Such Jesuits as Serrarius, Petavius, Sirmond, Tursellinus, Bellarmín, Balde, Mariana, and Flechier advanced the sciences of history and geography, the study of language and rhetoric, even beyond the limits of their own order and church.

Scheiner and Boscovich were eminent in mathematics and astronomy. No men understood better than the Jesuits the art of showing off, to the best advantage, their really valuable services; the world could not but acknowledge them to be improvers and benefactors of their age. Accordingly, their houses and possessions visibly increased, their churches and confessionals were not empty; they contrived, too, with much address, to obtain legacies and presents, and to seize upon every advantage which pious credulity and the extent of their connexions presented them. They would not allow their internal constitution to be inquired into or imitated; and when, in 1623, a number of enterprising females in Italy, and on the Lower Rhine, formed a plan of uniting into an order, under the name of the *Jesuitines*, to be modelled after the society of Jesus, they repulsed all the advances of their would-be sisters, and, in 1631, procured a papal decree for the abolition of the new order. But in England, and the Protestant states of the North, they were not so successful, their repeated attempts to establish themselves there proving fruitless. In 1618, however, the number of members amounted to 13,112, in thirty-two provinces, without including those in France, the Rhenish provinces, and the Netherlands, Poland, and Lithuania, Spanish America, the Philippines, and China. Elated with this success, they celebrated, in 1640, under general Vitelleschi, the centennial anniversary of their order, with great pomp. There were some circumstances, however, to damp their exultation; for, notwithstanding the great favour which they enjoyed at court and among the people, the non-Jesuit clergy and the learned men of the age soon discovered the mischief which the society was beginning to do through Christendom. The universities, bishops, and clergymen found their interest opposed to that of the Jesuits, whose privileges, where they were carried into effect, would be necessarily injurious and oppressive to the body of teachers and the clergy. The ancient orders of monks, whose hatred they had excited by their encroachments on their province, as much as by their good fortune, found subject enough for complaint and bitter accusations in the duplicity and worldliness of their conduct. They made no scruple of invading what had been regarded as the appropriate province of other orders, and were on the best terms with the Carthusians, who, on account of their vow of silence, were the only ecclesiastics, out of their own body, to whom the Jesuits were permitted to make confession. Their busy, intriguing spirit made them the objects of suspicion and jealousy to statesmen and jurists, on account of their interference in political affairs, the mischievous effects of which were already manifest in Portugal, under the reigns of John III. and Sebastian, their pupils, and, after the death of the latter, were a principal cause of the surrender of this kingdom to the Spanish crown. For this reason, the parliament and higher clergy of France, for twenty years, resolutely resisted the attempts of the Jesuits to gain a footing in that country. The university of Paris also declared the whole order to be useless, and its existence incompatible with the rights of the Gallican church. It was owing chiefly to the favour of the court, that they at last, in 1562, were admitted into France under the name of *fathers of the college of Clermont*, with a humiliating renunciation of their most important privileges. Notwithstanding this depressed condition, they soon contrived to establish themselves in Paris and the southern and western provinces, and, during the civil commotions, under the protection of the Guises, to deprive the French Protestants of their rights, gradually to establish their privileges, and to maintain their footing, in spite of the suspicions enter-

tained of their having had a share in the murder of Henry III. They were banished, indeed, in 1594, on account of the attempt upon Henry's life by their pupil, John Châtel; yet they still remained undisturbed in Toulon, and Bourdeaux, and, at the intercession of the pope, were again received by Henry IV. in 1603. They soon, in their office of court-confessors, carried on the same intrigues as before. Their participation in the crime of Ravallac, though exceedingly probable, could not be proved against them; they themselves joined in condemning the book in which the Spanish Jesuit Mariana defends the king's assassination, and, by cunning and obsequiousness towards the court, preserved themselves undisturbed. They made themselves still more important to the German empire, when they became the confidential advisers of Ferdinand II. and III. They discovered remarkable political talent in the thirty years' war; the league of the Catholics could do nothing without them. Father Lamormain, a Jesuit, and confessor to the emperor, effected the downfall of Wallenstein, and, by means of his agents, kept the jealous Bavarians in their alliance with Austria. But, while they were thus successful as statesmen, in this part of Europe (though they failed in preventing the triumph of toleration at the peace of Westphalia), a new storm burst upon them, in France and the Netherlands, from the Jansenist controversy. The ancient hostility of the university of Paris, which had always been strongly averse to the admission of the Jesuits as teachers, rose up, in union with the rigid morality of the Jansenists, against the notorious semi-Pelagianism of Molina and his brother Jesuits. (See *Grace*, and *Jansenius*.) The character of the Jesuits received a fatal wound from the pen of Pascal, whose famous Provincial Letters exposed the mischievous doctrines and practices of the Jesuits with admirable wit and argument, to which they opposed little but abuse and violence. These letters, which have been published in numerous editions since 1656, were read through all Europe, and their testimony quoted in the sentence of condemnation pronounced by Innocent IX., in 1679, against sixty-five offensive propositions, mostly of Jesuit casuists. But it availed them little that royal decrees and papal bulls, procured by the Jesuit confessors of Louis XIV. (La Chaise and Le Tellier), were levelled against Jansenism, and its ruin completed by the well-known constitution *Unigenitus*. In the minds of reflecting and well-disposed persons, they still remained suspected of an attachment to the principles of their most eminent casuists, attacked by Pascal—principles which afforded the most startling solution of their crafty and ambiguous conduct. A lax morality, accommodated to the inclinations of a licentious age, which made interest and external circumstances the rule of conduct, and consecrated the worst means for a good end; their probabilism,—a system of principles and rules of life which tolerated every thing that could be defended as probably admissible; their excuses for perjury and crimes of all kinds, sometimes by arbitrary perversion of language, sometimes by ambiguous expressions and perplexing interpretations, sometimes, too, by mental reservations, according to which a man had only to think differently from what he said and did, to be justified, in his own sight, from the greatest crimes;—these, and other traits of a like nature, may be more fully and accurately learnt from the letters of Pascal, or the writings of the Jesuits, Sanches, Bauny, Escobar, Suarez, and Busembaum. Their own defences against these charges only confirmed the suspicion excited against their system of morals, while they palliated and conceded a part where the whole was culpable. Other accusations were now

brought against them, which they were still less able to repel. Their superficial mode of instruction, and the theatrical disorders of their schools, had been already condemned by Mariana, a learned Spanish Jesuit; the gross selfishness of the order had been publicly exposed in Sciotti's *Monarchia solipsorum*; the indifference with which they permitted their heathen converts to continue their old worship of idols, on condition of their mentally adoring, at the same time, Christ and the virgin Mary; and their want of agreement with the other missionaries in China, had been warmly, but ineffectually, censured by several papal bulls. Their conduct, too, was now and then discovered to harmonize too well with their indulgent code of ethics, as they were not always prudent enough in the commission of their excesses; and it was for this reason that the Iroquois, who had been converted by them, expressly stipulated in a treaty of peace (1682) for the removal of these licentious brethren, who did every thing that Jesus did not do. It was even found necessary to expel them from some of the Italian states for their licentiousness; and the horror which was felt through Europe at the trial of the Jesuit Girard, for the alleged violation of Cadière, an innocent girl, at the time of confession, is hardly yet forgotten. It was now becoming, every day, more evident to the world, that the Jesuits were not aiming to promote virtue and religion, but their own interests. This was confirmed by the complaints of merchants at the extensive traffic of the society of Jesus in the products of their foreign missionary stations. It cannot be denied that the republic of natives, formed by them, under the authority of Spain, in Paraguay and Uruguay, in which they ruled with absolute power, and which, in 1753, contained nearly 100,000 subjects, was conducted by them with consummate policy and skill, and was, perhaps, the best means for civilizing those savages; but that they made also a trafficking establishment for the enrolment of the order, was shown on occasion of a treaty of commerce, by which Spain, in 1750, gave up some districts of this country to Portugal. The resistance which the natives made to the Portuguese, with an army of 14,000 men, commanded by Jesuits, finally obliged the contracting powers to annul the treaty. The Portuguese Jesuits, though they disclaimed all concern in this affair, underwent a prosecution, which was not terminated, when an attempt upon the life of the king of Portugal hastened their downfall. The minister Pombal made out their agency in this attempt to a high degree of probability, and finally succeeded, in 1759, in expelling them from Portugal, and confiscating their possessions, by an edict, in which the king declared them guilty of high treason. Before this first blow, the order consisted of twenty-four professed-houses, 669 colleges, 176 seminaries, sixty-one novitiate-houses, 333 residences, and 273 missions in heathen and Protestant countries, and 22,589 members of all ranks, half of whom were ordained priests. In France, where Choiseul and Pompadour were unfavourably disposed towards them, their ruin was occasioned by the trade which they continued to carry on, in spite of all the pope's orders to the contrary. In 1743, they had established a trading-house at Martinique, by their deputy, father La Valette, under pretence of a mission, which soon monopolized nearly the whole trade of that and the neighbouring islands, and had commercial connexions with the principal merchants of France. It happened that two ships, with a cargo valued at two millions of francs, sent over by La Valette to pay the house of Lioncy, at Marseilles, fell into the hands of the British. The Jesuits refusing to make any indemnification for the loss, the

above-mentioned house brought an action against them, which terminated in the sentencing of the former to make full reimbursement, and was the means, also, of bringing to light other abuses of the order. Lorenzo Ricci, their general, refusing to make any change in their constitution, by the declaration, *Sint ut sunt, aut non sint* (Let them be as they are, or not be), the king issued a decree, in 1764, abolishing the order, in all the French states, as a mere political society, dangerous to religion, whose object was self-aggrandizement. In vain did Clement XIII., in a bull issued at the same time, recommend the Jesuits as the most pious and useful members of the church. They were also driven out of Spain, in 1767, and soon after from Naples, Parma, and Malta, by the efforts of Choiseul and the Spanish minister Aranda. The voice of public opinion at length compelled pope Clement XIV. to publish his famous bull, *Dominus ac Redemptor noster*, of July 21, 1773, by which the society of Jesus was totally abolished in all the states of Christendom. These measures were every where executed with a quick and strong hand, because a formal process would have given time for a formidable opposition. Yet their most important treasures and documents were already taken out of the way, as it is supposed, and their archives and coffers did not satisfy expectation. Ricci, who might have averted this fate by making some concessions towards a change in their constitution, protested the innocence of their order, which was bound to regard every thing which came from him as necessarily right and obligatory; but, in fact, the great infringements on the natural rights of others, incompatible with every well-ordered church or state, which were in a manner legalized by their privileges, rendered the existence of such a body in a state a political solecism. Unquestionably the world had much reason to rejoice at their fall, although a great part of the members were entirely innocent; and their former services will always be gratefully remembered. The ex-Jesuits, however, suffered no further penalty than being obliged to quit their houses, lay aside the garb of the order, renounce all intercourse with one another, and either enter some of the other orders, or put themselves under the superintendence of the bishops. They received annuities from the revenues of their confiscated estates, except in Portugal. In this kingdom, and in Spain, the ex-Jesuits were also prohibited from residing in the country; while, in the States of the Church, in Upper Italy, and in Germany, where they were treated with the most forbearance, in Hungary, Poland, and even in France, they were suffered to remain as private persons. Frederic II., indeed, would not join in the general expulsion of the order, in order to gratify his Catholic subjects in Silesia, to retain a school-establishment which cost him nothing, and to keep a productive source of revenue. Nevertheless, the Jesuits in the Prussian states were obliged to give up the garb of their order, and to renounce their constitution. Under the name of the *priests of the royal school-institute*, they were henceforth confined to the office of instructing youth; and even this institution was abolished by Frederic William II. Russia was now the only country that remained to them. Peter the Great had expelled them from his empire as early as 1719; but, in 1772, several houses of their order fell, with the eastern part of Poland, under the dominion of Russia. Catharine spared them, even after the abolition of the order, out of regard to her Catholic subjects, and on account of the usefulness of their schools. The patronage of Czernitscheff and Potemkin enabled them to obtain permission to erect a novitiate-house in 1779, and in 1782 to choose a vicar-general. Meanwhile, cir-

cumstances had taken a favourable turn for them in Rome. Clement XIV. died 1774, and his successor soon showed himself a friend of the society, which was yet very far from being extinct. The ex-Jesuits, who were deprived at once of their offices by the decrees of abolition, having been condemned unheard, still remained respectable clergymen, who had powerful friends in all classes, and were intrusted with important stations in the church and offices of instruction. In the year 1780, there were 9000 of them out of Italy, who were thought to maintain a constant union, under private directors or superiors; they were also thought to have possessed themselves of the secrets of the Rosicrucians, and to have taken a part in the schemes of the Illuminati. They were charged, moreover, with a plot to destroy Protestantism. But the clamour against them was, no doubt, often unfounded. By *Jesuitism* was still understood, not only the opposition to all ideas and institutions unfavourable to the Roman church, but also the sly and insidious arts of intrigue, the acting according to the principle that "the end sanctifies the means," the concealed movements of a manœuvring ambition, under the mask of piety and devotion to the public good, which had become a second nature with many of the followers of Loyola. Undaunted by these assaults of an often unjust prejudice, the ex-Jesuits, firmly united to each other, were hoping in the meanwhile for the restoration of their order, on which, according to their belief, the welfare of mankind depends. An attempt, in 1787, to revive their order, under the name of *Vicentines*, was unsuccessful. The *Fathers of the faith*, an ecclesiastical order founded by Paccanari, a Tyrolese enthusiast, and formerly a soldier of the pope, under the patronage of the archduchess Mariana, was composed mostly of Jesuits, and put in operation at Rome, by the aid of the easily persuaded pope, as a new form of the society of Jesus, under altered regulations; but they were never recognised by the secret superiors of the ancient Jesuits, as their brethren. The plans of the Jesuits were aided by Pius VII. He established their order in White Russia and Lithuania, where it continued in operation, but confined to offices of teaching and priestly duties, under the vicar-general, Daniel Gruber; and silently restored them, in 1804, in the island of Sicily, which was entirely separated from Europe by the fate of the continent. Hence it excited no surprise among observing men, that this pope, who, in 1806, had canonized a Jesuit, should make use of the first opportunity to revive the order. The bull issued to this effect (*Solicitude omnium*, Aug. 7, 1814), speaks of urgent entreaties and a general desire of the Christian princes and bishops for the restoration of the society, which restoration is called a *restitution*, thereby intimating that it would again appear in precisely the same form in which it had fallen. Accordingly, the novitiate at Rome was solemnly opened, November 11, 1814, and about forty men, mostly eminent for rank and attainments, have since been admitted. In 1824, they took possession of the *collegium Romanum* in that city. In 1815, a college was given them at Modena, and they did not delay to accept the invitations of the kings of Sardinia, Naples, and Spain. Ferdinand VII. (May 29, 1815) reinstated them in the possession of all the privileges and property which had been taken from them in 1767. He subsequently appointed St Ignatius captain-general of the Spanish army, and conferred on him the grand cross of the order of Charles III. The Helvetic canton of Friburg, also (September 15, 1818), restored the old Jesuit college, formerly established there, for the instruction of youth. The Spanish revolution of March, 1820, was followed by their banishment from the kingdom; but

they were restored again at the re-establishment of absolute power in 1823. Thus, in the conduct and the fortunes of the order, have been fulfilled the prophetic words of their third general, Francis Borgia: "Like lambs have we crept into power, like wolves have we used it, like dogs shall we be driven out, but like eagles shall we renew our youth." Portugal alone steadfastly adhered to its ordinance of September 3, 1759, which banished the Jesuits out of the kingdom. Germany has hitherto refused to admit them; but the Paccanarists and Redemptorists in Austria have much in common with this society: some of the Jesuits, indeed, were allowed to take refuge there, after their banishment from Russia, but were commanded, in 1825, on pain of exile, to acknowledge the archbishop of the province as their supreme head. In France, the ultra-royalists succeeded in causing their presence to be connived at, and they already had congregations and seminaries at Montbrun, St Acheul, &c., previous to the late revolution. In Russia, where they had been expelled by Peter the Great, and re-admitted by Catharine II., it appeared that they were using their endeavours to win over the sons and daughters of distinguished families to the Catholic church, and they were banished in consequence, by an ukase of Jan. 1, 1817, from Moscow and Petersburg. But, still carrying on their proselyting schemes, and making themselves obnoxious to the government by secret intrigues of all sorts, an imperial ukase of March 25, 1820, abolished their order for ever in Russia and Poland, and provided that the whole body of its members should be transported beyond the boundaries of these two countries, at the expense of the government, having regard to the age and bodily condition of individuals; that the valuable estates of the order should be confiscated, and the academy at Polotsk abolished. In England, the tolerating spirit of the British constitution has permitted them, for the last thirty years, to have a college at Stonyhurst, near Preston in Lancashire, with an academy of 500 pupils, and several smaller boarding schools, from which they carry on with success, the propagation of the Catholic faith. (See Dallas's *History of the Jesuits*, London 1816.)\* They have also three colleges in Piedmont, one in Ferrara, one in Ireland, one in Friburg in Switzerland, and two colleges in the United States, one in Georgetown, in the district of Columbia, the other at St Louis, Missouri.

The Jesuits have outlived their power; the age rejects them. The world is ruled by a spirit with which this fraternity, now inconsiderable in point of numbers, talent and influence, could not keep pace. The sagacious statesmen of the present day need not to be reminded of the answer of Maintenon, the mistress of the great patron of the Jesuits, who, on having chosen Lazarists for the spiritual guides of her pupils at St Cyr, was asked why she had not taken Jesuits; "Because," she replied, "I would be mistress in my own house." The order originated in a wise view of the state of the world on the part of leading Catholics, who saw that the rapid advances of the Protestants in learning and science would soon throw the old system of ignorant mendicant orders into contempt. They therefore trained a new race of combatants for the church in the use of intellectual

weapons; but the advantages, which they thus obtained originally, have been lost in the general spread of intelligence, and the Jesuits are now considered as a part of the old regime, and no longer influence public opinion. Their conduct of late years in France has not tended to restore their popularity. The disposition to adapt them to the new order of things, however, has been shown in the acquittal, by the court of Rome, of two Jesuits charged with having spoken well of republics, on the ground that, being citizens of the United States of America, they had a right to defend republican principles.

A Universal History of the Jesuits was published by Wolf (second edition, Leipsic, 1803, 4 vols.). An important historical work, drawn from the first sources, appeared at Leipsic, in 1820, called *Catechismo dei Gesuiti* (Catechism of the Jesuits). The *Monita secreta Societatis Jesu* (Paderborn, 1681) have been reprinted in Latin and German, at Ailla-Chapelle, 1825, with a report of M. Portals, respecting the *Pères de la Foi*. The genuineness of these *Monita*, &c., however, is not fully established. See, also, *Hist. des Confesseurs des Empereurs, des Rois, &c.*, by M. Grégoire (Paris, 1824); also *Procès de l'Histoire générale de la Compagnie de Jésus, suivie des Monita secreta*, by Arn. Scheffer (Paris, 1824); De Pradt, *Du Jéuitisme ancien et moderne* (Paris, 1826); and *Les Jésuites modernes*, by abbé Marcial Marcet de la Roche Arnauld, formerly a Jesuit (Paris, 1826). See the following article.

**JESUITS** [written by a Jesuit]. In the preceding article, the opinions of the opponents of the Jesuits are given, and we propose now to give a brief outline of the views of the Jesuits themselves respecting their order, taken from the article *Jesuits*, written by one of the society, for the *Conversations Lexicon*.—The middle ages had ended. It was no longer a question whether the exercise of simple faith was sufficient; societies formed for the contemplative life—the monks—could, in future, have but a subordinate value for the church: the question was now, how to find effectual means to save the Catholic religion and church against the attacks of the spirit of innovation. As action, in the natural world, always produces reaction, so it in the moral world. A new order originated in the church—the Jesuits. It is true, the intention of Ignatius Loyola was originally directed rather to mystic and ascetic contemplation; but the order soon took a shape adapted to the wants of the church. Ignatius Loyola was a Spaniard of a very warm imagination and great sensibility, which early awakened in him a zeal for religion. After having served against the infidels, he founded a religious society. In the convent of Montserrat, in an almost inaccessible wilderness of Catalonia, he copied the rules of a holy life, which an abbot, cousin to cardinal Ximenes, the minister of state, had prescribed. The inflamed mind of Ignatius saw Mary, the mother of Jesus, in a vision: she gave him the power of chastity. Jesus and Satan appeared to him in the form of military officers enlisting men for service; he followed Christ. The order was founded in 1540. After the death of the founder, the society was further developed by Lainez, and, after him, by Aquaviva, men of deep knowledge of mankind, and steadfast purpose, the real authors of the success which, as John Muller said, deserves to be compared with the great institutions of the lawgivers of antiquity. The object of the society was, as it is described in their institutions, to devote all the powers to the salvation and perfection of the souls, and those of their neighbours, and to occupy themselves for this end in all places, according to the direction of their superiors. The society designated their object by the motto of Ignatius—

\* By the Catholic relief bill (April 13, 1829) it is required that every Jesuit in the United Kingdom shall register his name and place of residence with a clerk of the peace; that any member of the order who shall enter the realm shall be guilty of a misdemeanour, and, on conviction, be banished for life (any natural born subject out of the realm, being a Jesuit, is, however, permitted to return); the admission of any person to the order is also forbidden; both those admitted and the members who administer the engagement are liable to fine and imprisonment, or banishment.

*Omnia ad majorem Dei gloriam.* Severe trials, constant inspection, unconditional obedience in permitted things, ensured the intimate union of the society, as well as the ability and purity of its members. A strictly decorous exterior was enjoined. No Jesuit was allowed to confess a woman, except in the presence of another Jesuit. Money a Jesuit never was allowed to take for masses. The seat of the society was in so far in Rome, as the general of the order resided there, with the committee of the society, and the monitor, who, totally independent of him, controlled the general as if he were his conscience. The order was divided into provinces, each of which was superintended by a provincial. Under the care of these officers were the professed-houses, with each a *propositus* at its head, and the colleges, with each a rector. In the latter, there were also novices. The mutual dependence of all parts of the system resembled the structure of a well-built fabric: the relations of subordination were so ordered that the society was *simples duntaxat unum*, without interrupting the free will of the individual, who only had to obey in permitted things. The Jesuits were active, first, as teachers of youth. Lord Bacon says of them, that, when he considered the assiduity with which they gave themselves to the cultivation of science and the maintenance of pure morals, he always thought of what Agesilaus said to Pharnabazus, "As thou art such, I wish thou wert one of ours;" and that, in regard to the method of teaching, the Jesuit schools ought to be taken for models, because, of every mode which had been attempted, none was so good as theirs. Thus far Bacon. But what gave the greatest value to their mode of education was, that with them, religion ruled over every thing: they formed Catholic Christians of a sound mind, not unsettled spirits, like the youth of our times. Their care for the purity of youth was remarkable; and ought they to be reproached because, with this view, they mutilated the classics? A chief object of the Jesuits was the defence of the church against Protestantism. There is no doubt that the reformation would have spread much farther, had not the Loyolites fought for the church. If they were thus anxious to preserve Catholic souls, on the other hand they were not less active to propagate the gospel in distant countries. They took the usual vows of the orders—chastity, poverty and obedience; the latter in so extended a sense, that they were willing to go on any missions. With apostolic zeal, they devoted themselves to the task of converting the heathen. In the heart of Asia, in Japan, and in the Moluccas, they erected the sign of the crucified Redeemer, and preached the doctrines of the gospel: they taught it in China, in both the Indies, in Ethiopia, and among the Caffres. When the church was persecuted in Japan, the Jesuits all became martyrs. One only, Christopher Ferreira, wavered. Exhausted by long continued torments, and by the expectation of still greater ones, he, in a weak hour, was induced to sacrifice to the Japanese gods. But hardly had the news of this deplorable event arrived in Europe, when Jesuits from all the provinces offered themselves as missionaries to Japan, and begged for permission to go there as a favour. Their object was either to bring back Ferreira to the church and the order, or to wash out, with their own blood, the stain of his ignominy. All who were now sent to Japan suffered martyrdom immediately. Ferreira's conscience was soon awakened again: he repented, and went before the magistrates, acknowledging himself a Christian. He was tortured for eight days, in every possible way, and was at last sunk into the Japanese den of death, where, after seven days, death put an end to his torments and repentance. In the other hemi-

sphere, the Jesuits penetrated into the north. The Hurons were civilized, and Canada ceased to be the residence of barbarians only. Others civilized other tribes in the inclement California, and united them into Christian communities.\* At the same time, others traversed the regions north of Mexico, inhabited by wandering tribes, whom no missionary had ever visited before. Others continued the work of conversion in South America, in Brazil, Paraguay, &c. In this region, where the Spaniards had done nothing but murder and pillage, the Jesuits restored humanity to its rights, and brought the European name once more to honour. Their state, Paraguay, was one of the most beautiful creations in history. Whatever poets and philosophers have fabled of the golden age and the world of innocence, the Jesuits, as Raynal says, realized in a distant zone. Raynal, certainly an unsuspected witness, observes, "Perhaps so much good has never been done to men with so little injury. The people of Paraguay had no civil laws, because they knew of no property; nor had they criminal ones, because every one was his own accuser, and voluntarily submitted to punishment. Their only laws were the precepts of religion. There was no distinction of stations, and it is the only society on earth where men enjoyed equality. None were idle, or fatigued with labour. The food was equal, in wholesomeness, plenty, and quality, for all the citizens; every one was conveniently lodged, and well clothed; the aged and the sick, the widows and orphans, were assisted in a manner unknown in other parts of the world. Every one married from choice, and not from interest, and a number of children was considered as a blessing, and could never be burdensome. Debauchery, the necessary consequence of idleness, which equally corrupts the opulent and the poor, never tended to abridge the duration of human life; nothing served to excite artificial passions, or contradicted those that are regulated by nature and reason. The people enjoyed the advantages of trade, and were not exposed to the contagion of vice and luxury. Plentiful magazines, and a friendly intercourse between nations united in the bonds of the same religion, were a security against any scarcity that might happen from the incostancy or inclemency of the seasons. Public justice had never been reduced to the cruel necessity of condemning a single malefactor to death, to ignominy, or to any punishment of long duration; and the very names of taxes and lawsuits—those two terrible scourges which everywhere else afflict mankind—were unknown." It will not now surprise us, that Montesquieu, in his *Esprit des Loix* (liv. iv. ch. 6), Buffon, in his *Contemplations on the Variety of Human Races*, Albert von Haller, in his miscellaneous treatises on several subjects of politics and morals, Robertson, in his classical History of Charles V. and Muratori, mention, with enthusiasm, the services of the Jesuits as missionaries. Respecting the service which they have rendered to science, there is almost but one voice. No branch was excluded from their care. In theology, they were distinguished teachers: yet their enemies—and they had many, not only among the Protestants, but among the Catholics, and among these latter the most vehement, because of their great privileges, their freedom from the monkish spirit, and their great acquirements—have reproached them with maintaining many odious opinions. They are said to have defended the murder of tyrants. No charge could be more false. Even 126 years before

\* The well-known barbarous state of the above-mentioned tribes will lead the reader to qualify the meaning of the words *civilization* and *conversion* in other parts of the above article.—Ed.

the foundation of the order of Jesuits, John Petit, doctor of the university of Paris, asserted, without any qualification, the legality of the murder of a tyrant. The cause was the murder of the duke of Orleans, in broad day, in the streets of Paris, at the instigation of the duke of Burgundy, his competitor for the regency of the realm during the insanity of Charles VI. John Petit wrote a defence for the duke of Burgundy, in which he defends this horrid act, on the ground that the murder of tyrants is justifiable. The archbishop of Paris condemned this publication; but several French theologians, among whom there were even bishops, defended John Petit's doctrine; and when, some years after, Châlier, a doctor of the Sorbonne, denounced Petit's doctrine, at the council of Constance, before the assembled fathers, Martin Porre, bishop of Arras, defended it as being a doctrine which had been maintained by many learned men and theologians without contradiction. The council was at first undecided, but, at last, condemned, not all the positions of John Petit, but only this one: "Every tyrant may be legally killed by his subjects." According to this sentence, it appears as if the murder of tyrants is permitted under certain circumstances, and this question became a common subject of investigation among the theologians and scholars of the fifteenth century, and down to the middle of the sixteenth. In spite of the condemnation of the main point of this doctrine by the council of Constance, many theologians, chiefly belonging to the order of Dominicans, supported it. At a later period, also, distinguished Protestants upheld the doctrine, as Milton, Buchanan, Bodin, Beza, Du Moulin, and others. The Jesuits took part in this as in all theological questions, but not, as has been said, in order to develop this obnoxious doctrine, but rather to put it down by argument, or to make it as little obnoxious as possible. The learned Jesuit, Salmeron, Loyola's companion, says explicitly, nobody is authorized to kill a prince, even if the latter has obtained possession of the government by violence, particularly if he is once in quiet possession of power. Salmeron, indeed, in another passage, teaches that, if an illegitimate ruler attacks a city, and is just on the point of getting possession of it by arms, in such case, he may be lawfully killed by a private person, having received a commission to such effect from the legal authority. Here Salmeron indeed wrote in the spirit of his time; but it was no small step to confine within such narrow limits the authorized destruction of a tyrant, whilst the principle had been laid down with very little qualification, by many Catholics and Protestants of distinction. In the same sense other Jesuits have written, of whom some declared themselves still more distinctly against the doctrine: thus, for instance, the Jesuits Molina and Lessius said, "A regent, be he even a tyrant, is, nevertheless, the legal sovereign: hence the Holy Scriptures commanded obedience, even to heathen princes, in every thing which is not against the ordinances of God, even if they were the greatest tyrants, persecuted the church, and strove to force Christians to give up their faith. Hence it follows, that the murder of a regent is in no case permitted." Of all the Jesuits, about twelve in the whole, who occupied themselves with this question, only Mariana, in his book *De Rege et Regis Institutione*, upheld the doctrine authorizing the killing of tyrants, and even he with some restrictions. But hardly had Mariana's book appeared, when several Jesuits, particularly Bellarmine, completely refuted his doctrine *de tyrannicidio*; and Aquaviva, the general of the order, after some years, condemned this doctrine, and prohibited all the men of the society from touching the question any more, either directly or indirectly. From

this time, this subject has been banished from their schools and their works. Hence Voltaire, when he was believed to make common cause with the enemies of the Jesuits in the accusation of their defence of tyrannicide, says, "Posterity would unanimously exculpate the order, if I were to accuse them of a crime, of which every man of sense, nay, all Europe, and even Damiani, have acquitted them long ago." Another and equally unjust reproach against the Jesuits is, that their system of morals was lax, that they adhered to *probabilism*. Probabilism was, even 100 years before the foundation of the order, the common doctrine of all bishops, the most distinguished universities, and all the regular clergy. Under certain restrictions, this doctrine is far from being injurious to pure morality. The substance of it is, that where a law is not pronounced clearly, it is permitted to follow that opinion which, being likewise supported by good reasons, favours the natural liberty of man rather than the severity of the law. Next arose the question, whether it was permitted to follow the probable meaning, in preference to the more probable. The probabilists answered in the affirmative. This was asserted by many theologians, particularly Dominicans, long before the origin of the society of Jesus. But, as this doctrine is susceptible of an application really dangerous to morality, the Jesuits had the undeniable merit of having been the first who wrote against probabilism. The wranglers of the Jesuits Robello, Molien, Gisbert, Aquaviva, Gonzales, Dama, and others, contain unequalled attacks on probabilism, and attempts to reduce it within reasonable limits. The Jansenists, who were ready to make any charges against the Jesuits, first attacked them on the ground of their upholding probabilism. Pascal and Nicol were the first assailants: the former wished to make the Jesuits ridiculous, the latter, to make them odious. Perrault and Arnaud joined them at a later period. But all these publications were declared by the parliaments of Paris and Bourdeaux, who were by no means generally in favour of the Jesuits, "calumnious writings, filled with injustice, deceit, falsifications and ignorance." If Pascal's *Lettres Provinciales* are regarded as an authority against the Jesuits, we should at least consider what Voltaire says: "It is clear that this work (the *Lettres Provinciales*) rests upon a premise totally erroneous, attributing the insane opinions of some Spanish and Flemish Jesuits to the whole order. In the casuistry of the Dominicans and Franciscans, many absurd things might also be found. But the Jesuits alone were to be held up to general derision. The same letters even attempt to prove that it is the plan of the Jesuits to make men worse, instead of correcting them; but such a plan is so senseless, that no sect in the world ever had or could have it." The private lives of the Jesuits were exemplary. The purity of their morals is evident from the disgust which all Europe felt when a thing unheard of happened, when a Jesuit—one of a hundred thousand who composed the order—Girard by name, was accused of rape. There has never existed a society where such deviations from virtue have been met, even if we allow the *Amores Marcelli*, published by Von Long, to be true. The least suspected writer of the Jesuits is probably Voltaire: he says—"What have I seen during the seven years that I lived with the Jesuits? A very active life, connected with many labours, and, at the same time, very frugal and orderly. All their hours were appropriated to their school labours, and to the exercises which their severe order bound them to perform. I call thousands and thousands to witness, who, like myself, have been educated by them. I dare to affirm, that nothing more repulsive and dishonourable to human

nature can be found, than that there are men who reproach such people with laxity of morals." The history of the persecutions of the Jesuits, in the different parts of Europe, is very interesting. The first took place in France. In 1540, they appeared in France. The parliament hated them as friends of the Roman see, the university as dangerous rivals. The hall of the parliament incessantly resounded with the complaints of the university of Paris, who could not bear to see their students departing and putting themselves under the instructions of the Jesuits: still more painful was the loss of so many emoluments, which, under the name *Landis*, were derived from the students, while the Jesuits instructed gratis; and when, at length, the great fame of the Jesuit Maldorat, whose lecture-room was filled two or three hours before the time of the lecture, and who was at last obliged to lecture in the open air, spread farther and farther, the rage of the university rose to the highest degree. The rector of the university therefore intimated to them that they must close their schools. They obeyed; but an uproar took place among the students, and the court ordered the Jesuits to open their schools again immediately, and not to regard the arrogant pretensions of the university. Afterwards, however, when public business kept the king and his ministers for a long time from Paris, the university accused the Jesuits before the parliament. Pasquier, Arnaud, and Doulon, the advocates of the university, loaded the Jesuits with calumnies. Their advocate, Versaris, defended them so powerfully, that even the parliament, hostile as it was to the Jesuits, acquitted them. When, at a later period, Henry IV. besieged Paris, the Jesuits attracted new odium, by asserting, when interrogated by the citizens, in opposition to the opinion of the other theologians, that excommunication was not the necessary consequence of opening the gates to a heretic king. All the old hatred broke forth anew when Châtel attempted to murder Henry IV. The Jesuits were calumniously charged with being the authors of the attempt, and the parliament tumultuously and unjustly condemned to death the Jesuit Guignard. The judges themselves confessed, some years later, that they had acted over hastily, and all France acknowledged the innocence of the Jesuits. In the first heat, the Jesuits were banished from the realm by a decree of the parliament; but some parliaments in the provinces openly refused to register the ordinance of the parliament of Paris, and those particularly which were independent upon that of the capital, declared the act illegal, hurried, and unjust, and in general protected the Jesuits. For nine years, the Jesuits remained unmolested in Bourdeaux and Toulouse. Students from all France repaired to them, and the king was so much petitioned to restore so useful an order, that he recalled them. The parliament refused to register the royal decree, and sent a deputation to Henry, at the head of whom was the president Harley, who, as the historian Dupleix says, uttered a uniform strain of abuse against the Jesuits. The king answered with a speech extempore, which, as De Thou has not recorded it in his History of France, is hardly known, and we think it proper to give it here, to show how this able monarch spoke extempore: "Your care for my person and the welfare of my empire I acknowledge with pleasure. What you have just told me I have known long since; but my ideas on it were unknown to you. You speak of difficulties, which appear to you great; but I must tell you that I have weighed them duly seven or eight years ago. The best resolutions originate from the lessons of the past, and these I know better than any body else. You imagine that you understand affairs of government,

and that you may interfere with them, which seems to me much as if I should interfere with your duties by making a report in a civil process. I therefore must tell you, first, in regard to the affair of Poissy, that, if all had behaved as one or two Jesuits who happened to be present, every thing would have turned out better for the Catholics. Not their ambition, but their modesty, from that time, has appeared conspicuous; and I cannot conceive how you can accuse those of ambition, who refuse, constantly and unconditionally, abbacies, honorary offices, and dignities; nay, who oblige themselves by vows never to strive for them, and whose life, in general, has no other purpose than to be useful to all people. Is it the name *Jesuit* which excites your zeal? Then you must also dispute with those who have taken their name from the holy Trinity (*les pères de la Trinité*); and, if you believe that you belong as much to the society of Jesus as the Jesuits, you may ask yourselves whether your daughters belong as much to the *Filles de Dieu* in Paris as the nuns who bear this name, and you may as well call yourselves knights of the order of the Holy Ghost as myself and the other knights of the order. I, for my part, should like as well, or rather better, to be called *Jesuit* than *Jacobin* or *Augustine*. If part of the other clergy are hostile to the order, it may originate from the circumstance that ignorance always was hostile to science. I have found that, as soon as I declared my intention to recall the Jesuits, two classes of men immediately opposed the measure, viz., the Huguenots and all the Catholic clergy notorious for bad morals and conduct; but this gave me a greater esteem and love for the Jesuits." The king speaks at length on the reason why the Sorbonne could not agree with the Jesuits, because the latter were more learned, and that they should now not only be suffered, but take root within the realm.\*

In Britain, Jesuits never had much footing. The reformed doctrines had already become the prevalent religion of that country, when the order grew up. The Jesuits in Britain were only a small division of missionaries, who laboured among the dispersed and oppressed Catholics, quietly and under the veil of secrecy. Several Jesuits have suffered martyrdom in Britain, and several laws enacted against them manifest the grossest prejudice, and have been repealed only in modern times.—In the eighteenth century, the Jesuits received their first blow in Portugal. Pombal, minister of king Joseph, a powerful and passionate man, wished to promote the welfare of Portugal; but his plans were those of a despotic minister of a despotic government. Every thing opposed to his wishes was to fall. Many circumstances co-operated to render him inimical to the Jesuits, to whose influence, as confessors, he owed his elevation. It would have been better for the Jesuits if they had avoided accepting confessorships at court, in the same way as they declined the dignities of the church. Pombal believed the country of the Paraguay, in which the Jesuits ruled so paternally, contained a number of gold mines, unknown to the inhabitants. He therefore obtained this country from Spain by exchange for another, 1400 miles distant, into which he wished to transplant all the Indians of Paraguay. The Jesuits received orders to prepare the people for this measure. The natives remonstrated very modestly and respectfully against such a forced emigration, representing how impossible it would be to transplant 30,000 people, with all their goods to such a distance through the wilderness; but the government was inexorable. Only a few months were

\* The speech is long, and its genuineness very suspicious, as it goes carefully through all the points for which the Jesuits had been reproached. It is too long for a king, too systematic for an extempore performance.—Ed.

allowed them for preparation. The Indians, who were to be torn from the ground they had first cultivated, the huts where they were born, and the graves of their friends and parents, were reduced to despair. Even the Jesuits, who admonished them to obey, were now suspected by the Indians of conspiring with their heartless oppressors in Europe. The Indians armed themselves for resistance. A war broke out, in which the Indians were at first victorious, but were afterwards conquered. Many burnt their villages, and fled into the mountains, where most of them perished. After having searched in vain for gold every where, Pombal was ashamed of his bloody and bootless measure, and, under Charles III. of Spain, the lands were re-exchanged, after the innocent Indians had become accustomed to all the vices of European outcasts. But, as a despotic minister cannot err, the Jesuits were now to be proved the instigators of the resistance of the Indians to Pombal's humane project of emigration. To make the world believe this, Pombal laid a plan with a certain Platel, whose vices had made him an outcast from various countries. The world was to be persuaded that the Jesuits had maintained a warlike state in Paraguay for a hundred and fifty years, and even a king, Nicholas, who commanded their forces, &c. In Spain, the story was laughed at. People knew why Spaniards had been prohibited, with the consent of government, from visiting the missions—that they might not infect with European vices the innocent Indians. This prohibition was a point on which Pombal's writer always insisted. The statements of Platel were proved to be false by the governor of Peru and the Mexican bishops, and the book was burnt in Madrid; yet Pombal's libels found belief in Europe. The Jesuits were recalled from Paraguay, and imprisoned in Portugal. There were other reasons to excite the minister's anger against the Jesuits. In a question respecting the marriage of the king's daughter, the confessor of the king, the Jesuit Moreira, gave advice contrary to that of Pombal, and the king followed the Jesuit. In the papers of the queen, who died in 1754, Pombal discovered that the Jesuits in Maranhão had often apprised the queen, in consequence of her request, of the extortions, &c. of the governor of the place, the brother of Pombal. His passion rose to the highest pitch. Pombal had excited against him the proprietors of the vineyards of that country by a monopoly of port wine, from which he derived advantage himself, so that the inhabitants devastated his vineyards; the Jesuits, it was reported, had done it. When, after the dreadful earthquake of 1755, the Jesuits made use of this event to bring people to repentance, and the king even expressed the desire to devote himself for eight days to spiritual and solitary meditation, under the direction of the pious Jesuit Malagrida, this resolution of the king gave great uneasiness to Pombal, who feared for his influence. Cost what it would, the Jesuits were to fall. At the same time, another obstacle to Pombal's power was to be annihilated—the high nobility, with whom he lived in decided opposition. These two objects Pombal succeeded in accomplishing with one stroke. September 4, 1758, the king, on his return from a love adventure, was wounded by assassins. Pombal persuaded the king that this attack was owing to a conspiracy of the high nobility and the Jesuits, and don Joseph was now in constant fear of new conspiracies, and therefore totally in the power of his minister. The duke of Aveiro, the whole house of Tavora, were tried by an extraordinary committee, and suffered an ignominious death. Malagrida was arrested as concerned in the conspiracy, and, after several years, was sentenced

and burnt by the obedient inquisition as a heretic. When, with the death of don Joseph, Pombal's despotism was at an end, when the latter himself, being accused and convicted of the most execrable crimes, was sentenced to death by the court unanimously, and pardoned by the queen, and only punished by banishment, then also the affair of the conspiracy was reviewed, and the parties who had suffered were declared innocent. But, if the conspiracy really had existed, nothing proved the connexion of the Jesuits with it. It is true, the Jesuit Malagrida had, shortly before that attempt, declared that, if the king, who was given to sensual pleasures, did not reform his conduct, a great disaster would follow; and other Jesuits were the friends of Tavora and Aveiro. But none but Pombal could have made this circumstance the ground of an accusation against the society. He accused the whole body before the pope, and demanded its abolition. When the pope ordered the trial of the accused, Pombal, without waiting, exiled the Jesuits, sent back the papal nuncio, and broke off all connexion with Rome. One thousand, eight hundred and forty Jesuits were transported, in 1759, to Italy, and suffered the worst treatment. In France, also, the order declined. Madame Pompadour and the minister Choiseul were hostile to it. When the former had appeared at court, without any other claim than because she had become the king's mistress, the scandalous event excited general attention. As most people are more ready to violate the dictates of morality than conventional forms, madame Pompadour resolved to procure a legal title to appear at court, and adopted the idea of becoming *dame en palais* of the queen. But for this the approval of the good-natured queen was requisite, and it was concluded to deceive her by an appearance of repentance, and to make her believe madame Pompadour had ceased to be the king's mistress. A confession was necessary, and the choice fell upon the Jesuit De Sacy, a man apparently simple, who, it was supposed, would not penetrate the plan. But Sacy declared that, if it was really her earnest intention to return to virtue and religion, she must, without delay, leave the court, retire into solitude, and try to repair the evil she had done, by real repentance; until then he could not take upon him the direction of her conscience, and he never would profane the sacraments, and let himself be made a tool of in such an intrigue. This opposition awakened in madame Pompadour inveterate hatred against the order. Choiseul belonged to the philosophers, so called, who were opposed to all positive religion; and the Jesuits were greatly in his way, also, on account of his hatred against the dauphin, who loved the society. An opportunity was soon found to attack them. The Jesuit Lavalette, in Martinique, had been engaged in commerce; his vessels were taken by English privateers, and his bills of exchange were not paid; in consequence of which, the whole order, which certainly was not obliged to answer for Lavalette's illegal conduct, were called before the parliament, which nourished the old hatred against the society, and now counted, moreover, several Jansenists amongst its members. The order was condemned. The process was the signal for a general attack upon the Jesuits. Choiseul had several laws written against them, and the order abolished by the parliament without a hearing, though the bishops of all France declared in its favour. The process of the parliament was a mere farce. The total abolition took place in 1767. Meanwhile Charles III. ascended the throne of Spain, and assured the general of the order of his protection. But the minister Aranda, an intimate friend of Choiseul, praised by Condé as a decided enemy of priests, nobles, and kings,

was an enemy of the Jesuits, as was also his friend Campomanes, fiscal of Castile. They procured the exile of the Jesuits in a way that did them little honour. One evening, the rector of the Jesuit college at Madrid was apprized that a stranger wished to see him immediately. The stranger coming, as he said, from the Jesuit rector of Seville, gave to the rector of Madrid a parcel of papers, with the request that he would read them attentively, and make his remarks on them. The rector ordered the papers to be carried to his room, and, as the hour of meeting in the refectory had begun, went thither in order not to interrupt the prescribed order. Hardly had he arrived there, when the house bell was rung violently. Royal commissioners enter, and seal up all papers, including the packet just left, and carry them to Aranda. Not long after, in the night of April 1, 1767, all the Jesuit colleges in the kingdom were surrounded by soldiers at the same hour, and the Jesuits carried to the states of the pope. April 2, 1767, the king declared that he had resolved to keep the true cause of the banishment of the Jesuits secret. Pope Pius VII. some years before his elevation, first found the traces of this infamous intrigue. When a cardinal, he had been appointed by Clement XIV. a member of the committee who were to investigate the affairs of the Jesuits. The Spanish government, to justify itself somewhat with the pope, had sent the alleged proofs against the Jesuits to Rome. Among these were letters purporting to have passed between distinguished Jesuits, containing remarks of the most infamous character; among other things, it was said in them, that the king was an illegitimate son of cardinal Alberoni, and hence not entitled to the throne, &c. Of course, these letters must have excited the king, and prompted him to banish the order. But it was also found, by a comparison of the hand-writings, that these letters were forged. It was now evident who had brought the parcel only a few moments before the seizure of the papers in the Jesuit college in Madrid. The exile of the Jesuits, and several other circumstances, had caused a dispute between the pope Clement XIII. and Portugal and Spain. The pope (Reasonico) died, without an adjustment of the dispute having taken place. The election of his successor was now a matter of the highest importance. The question was, whether the Jesuit party should prevail or not. Cardinal Ganganelli had already, under Clement XIII., expressed his opinion, that it was more advisable to sacrifice the Jesuits, though innocent, than to live in constant dispute with the kings. The Bourbon party therefore supported him at the election. At the same time, in the conclave, he gained the friends of the Jesuits by maintaining that the new pope ought not to think any more of the abolition of the order than of pulling down St Peter's; and he was elected. The new pope, in fact, after his accession, said, in his missives to the courts of Versailles, Madrid, and Naples, that he neither could blame nor abolish an order which nineteen of his predecessors had solemnly confirmed; it could be the less expected of him, as the same had been confirmed by an oecumenical council at Trent, whose decrees, according to the principles of the Gallican church, were binding on the pope; but he would, if asked, call another council, in which the Jesuits should be heard, all questions investigated anew, and decided upon; that he was obliged to protect the Jesuits equally with the other orders; that, moreover, all the princes of Germany and the king of Sardina had written to him in favour of the Jesuits, and he therefore could not yield to the wish of some cabinets, which desired the abolition of the order, without drawing upon himself the displeasure of so

many other monarchs. But the papal letter was of little avail. The courts threatened the pope with the publication of his letters, written before he had acquired the pontificate, in which he promised to the courts the abolition of the Jesuits, if they would lend him their support in the election. The abolition was difficult, as Clement XIII., with the assent of the whole college of cardinals, had, a short time before, solemnly confirmed the order by the bull *Apostolicum*, and the immediate contravention of the bull would have been an unparalleled scandal, to which the cardinals never would have given their consent. There was no way left, therefore, but to choose the form of a brief—a decree which the popes issue without consulting with the college of the cardinals. In 1773, the brief was issued. The reasons for the abolition were not given in the brief; it was only said that the popes had abolished several other orders, and that the council of Trent had not exactly pronounced a confirmation of the order. Four weeks after this violation of justice, Ganganelli appointed a committee to investigate the accusations against the Jesuits! The Protestant historian John Muller says of this abolition—"It was soon apparent to wise men, that a common bulwark of all authorities had fallen." Prussia did not acknowledge the abolition, but retained the Jesuits, as useful instructors, in Silesia, until at last they themselves, from obedience to the pope, urged the king to complete their abolition. In Russia, also, the order remained, because Catharine was convinced of its utility; and the government obtained the necessary permission from the popes Pius VI. and VII. Clement XIV. died in 1774. His sickness and death were accompanied by strange symptoms, and calumny immediately accused the Jesuits of having procured his death. The persons in attendance on the pope, and the physicians, gave, however, no satisfactory statements; and Le Bret, in his Magazine of Political and Ecclesiastical History, so clearly showed the innocence of the Jesuits, that this calumny never could gain footing. (See *Clement XIV.*) The abolition of the Jesuits had serious consequences. In most Catholic countries, it produced a chasm in the means of public instruction, which it was not easy to fill. The education of youth lost, in many cases, the salutary religious direction which distinguished so much the instruction of the Jesuits. Neither the archives nor the coffers of the Jesuits satisfied expectation. Some persons believed the money to have been carried off; but nothing has been heard of it for fifty years. The order was reinstituted in White Russia in 1801, and in Sicily in 1804, and was put entirely on its old footing in 1814, by the pope. Whether it ought to be restored every where, is a question which, we think, is different from what it was formerly. In the southern countries of Europe, it appears capable of becoming very useful. Of its re-establishment in Germany, there is little hope. There is such a mass of knowledge distributed in the German nation, its public instruction is so thorough, and the establishments for education so well founded, that the Jesuit schools appear, at least, not to be needed. In this nation, too, materialism does not remain to be conquered, but the sound sense of the people soon led it back to religion. Besides, the society's plan of education would little agree with that of the Germans, because that of the Jesuits is by its nature a general, and therefore a stable one, and cannot adapt itself to modern systems of education.\*

\* The length of the articles on the Jesuits may be excused from the interesting nature of the subject. Any view, however, of the subject, which could be given in a work of the character of the present must be too concise to enable the reader to form satisfactory conclusions; to do

**JESUITES DE ROBE**; secular persons of high rank—as, for instance, Louis XIV. of France—who are bound to the order by vows of obedience, but have not taken the spiritual vows.

**JESUS**, called also *Christ* (*Xp̄stos*, the Anointed), the Son of God, the Saviour of men, whose birth, life, and death, were predicted by prophets, and attended with miraculous manifestations of divine power, was born of the virgin Mary, of the tribe of Judah, who was betrothed to Joseph, an obscure artisan. The place of his birth was Bethlehem: the time is uncertain, but is commonly considered to have been in the twelfth year of the consulate of Augustus, four or five years before the beginning of the vulgar era. Our information concerning him is derived almost entirely from detached sketches of his life, written by four of his followers. The angel Gabriel had announced to Mary, that the power of the Highest should overshadow her, and that she should bear a son who should rule over the house of Jacob for ever; and on the night of his birth, an angel appeared to some shepherds, and announced the coming of a Saviour. On the eighth day, he was circumcised according to the law of Moses, and, on the fortieth, was presented in the temple, where the aged Simeon pronounced him to be the light of nations and the glory of Israel. The coming of the divine infant was also hailed by the adoration of the Magi, who were miraculously directed to the house where the young child was. Herod, alarmed by these indications, determined to destroy all the male children of Bethlehem and its vicinity, of the age of less than two years, for the purpose of effecting the death of Jesus. But Joseph, being miraculously warned of the danger, fled to Egypt with the virgin and her child, and, on his return after the death of Herod, went to reside at Nazareth, in Galilee, whence Jesus is called a *Nazarene*. We have no further accounts of the earlier years of Jesus, except the remarkable scene in the temple, when he was twelve years old, and the general observation of Luke, that he remained in Nazareth with his parents, and served them. At the age of about thirty (*Luke* iii. 23), he was baptized by John in the river Jordan; the Spirit of God descending upon him like a dove, and a voice from heaven proclaiming, "This is my beloved son." Previously, however, to entering upon his office of divine teacher, he retired to a solitary place, where he passed forty days in fasting, meditation, and prayer. His mission is generally considered to have occupied three years, spent in acts of mercy, in inculcating a purer system of morals, more exalted notions of God, and more elevating views of man and his destiny, than had yet been presented to the world. If, when we consider his miracles, he appears like a God, we must also acknowledge something superhuman and divine in his purity of life, his warm love for others, and his self-devotion to their welfare; his meek yet firm and unshrinking endurance of insult, contempt, calumny, and suffering. While he denounces sin, and prophesies the coming desolation of the corrupt city, he forgives the sinner,

which, great knowledge of facts and critical acumen are requisite. The articles can only serve to indicate the most important points to be investigated. The second article was given to show what construction Jesuits themselves put upon the important charges against them. We may close with remarking, that every thing in history has its time, and the order of the Jesuits can never rise to any great eminence in an age in which knowledge is so rapidly spreading. It is connected with the old order of things, not with the new, and has twice returned with servilism into Spain, and once into France. The *Encyclopædie Moderne*, in its article on the Jesuits, calls them the *pretorian guards*, the *struttes*; the *jenicricks* of the pope; and it can hardly be supposed that the guards will flourish when the sovereign is daily declining in splendour and power.

and weeps over the fate of the obdurate Jerusalem. Nothing can surpass the perfect beauty of his life, but the godlike sublimity of his death. It is unnecessary here to trace the particulars of his short but eventful mission. He had chosen twelve apostles to be the companions of his ministry, the witnesses of his miracles, and the depositories of his doctrine, and he was betrayed into the power of his enemies by one of these, with the mockery of a friendly suggestion. Betrayed by one, denied by another, and abandoned by all, he was carried before the Jewish priests, found guilty, and by them delivered over to the Roman magistrates, who alone had the power of life and death. Condemned to death as a disturber of the public peace, he was nailed to the cross on mount Calvary; and it was in the agonies of this bitter death, that he prayed for the forgiveness of his executioners, and with a touching act of filial love, commended his mother to his favourite disciple. The evangelists relate that, from the hour of noon, the sun was darkened, and, three hours after, Jesus, having cried out, "It is finished," gave up the ghost. The veil of the temple, they add, was torn asunder, the earth shook, rocks were rent, and the tombs opened. The centurion who was present, directing the execution, exclaimed, "Truly then was the son of God." The body of Jesus was taken down by Joseph of Arimathea, and placed in a tomb, about which the Jewish priests, remembering his prophecy that he should rise on the third day, set a guard, sealing up the door. Notwithstanding these precautions, his prophecy was fulfilled, by his resurrection on the first day of the week (Sunday); and he appeared repeatedly to his disciples, to encourage, console, and instruct them. On the fortieth day after his resurrection, while with them on the mount of Olives, he "was taken up," and disappeared out of their sight.

**JESUS SIRACH.** See *Sirach*.

**JET.** The colour of jet is a pure and deep black, sometimes with a tinge of brown. It occurs in opaque, compact masses, so solid and hard that they are susceptible of being turned on a lathe and highly polished. Its fracture is conchoidal or unbroken, shining, or even splendid, and it has a waxy lustre; its specific gravity from 1.25 to 1.29. By friction, it acquires a weak electricity, even when not insulated. It sometimes presents the form of branches of trees, and exhibits traces of a ligneous texture. It burns with flame often a little greenish, but it does not melt, like solid bitumen. It exhales, while burning, a strong and sometimes aromatic odour, sensibly different from that of coal or bitumen. It most frequently occurs in detached masses of a moderate size, in beds of sandstone, marl, limestone, and secondary trap. It is also connected with formations of coal, particularly that which is associated with secondary trap rocks. It is also found with other varieties of lignite. Good specimens of jet are found in Galicia and other places in Spain; near Wittemberg, in Saxony; in the department of Aude, in France, where it sometimes contains small bones. In England, it occurs near Whitby. In the Færoe islands, and in the Isle of Sky, it occurs in trap rocks. In Massachusetts, America, it is found in South Hadley, in the coal formation. Jet is sometimes employed for fuel, but is more frequently cut and polished, for ornamental purposes, buttons, bracelets, snuff-boxes, &c. Some mineralogists consider it intermediate between coal and bituminous wood.

**JEUX FLORAUX** (*floral games*): a festival annually celebrated in Toulouse. As early as the times of the Troubadours, Toulouse had a literary institution, called the *collège du gai savoir*, or *de la*

*gai science*, as poetry was then termed. It was founded before the year 1323. Seven Troubadours and a chancellor formed the college; they conferred the degrees of doctor and bachelor, and taught in their palace and gardens the *lais d'amour* or *fleurs du gai savoir* (laws of love, or flowers of the gay science). In 1323, they sent a letter, in verse, to all the poets of the Langue d'Oc, inviting them on the 3d of May, 1324, to a poetic festival, where the composer of the best poem was to receive a violet of fine gold. The celebrated Troubadour Arnould Vidal won the prize. The *capitouls* (magistrates) of the city, who had likewise been invited, to encourage a festival so much to the honour of Toulouse, offered, in future, to furnish the golden violet. To increase the splendour of the annual celebration, two other prizes were added to the violet—an eglantine and a pansy, both of silver. Similar institutions afterwards arose at Barcelona, in the reign of king John, and at Tortosa, in the reign of king Martin. The original institution at Toulouse, on the other hand, began to decline, and, at the end of a century, was nearly extinct, when it was revived by Clemence Isaure. (See *Clemence Isaure*.) She left by will a considerable sum for the celebration of this poetic festival, which was now continued under the name of *jews florant*. Mass, a sermon, and alms-giving, commenced the ceremonies. Before the awarding of prizes, the tomb of Clemence was strewn with roses. More costly flowers rewarded the seal of the competitors. Four prizes were offered—an amaranthus of gold, of the value of 400 livres, for the best ode; a violet of silver, value 250 livres, for an essay in prose, which was of not less than a quarter nor more than a half hour in reading; a silver pansy, value 200 livres, for an eclogue, elegy or idyl; and a silver lily, value sixty livres, for the best sonnet, or hymn, in honour of the holy virgin. Instead of doctors, there were now a master of the games, and forty judges (*mainteneurs*). In 1694, the college was formally erected into an academy. The office of chancellor, and other distinctions of rank, were abolished in 1773. The seal is kept by a standing secretary, and one of the members presides, with the title of *modérateur*, who is appointed by lot every three months. After an interruption of fifteen years, from 1790–1806, the *mainteneurs* assembled again in Toulouse, the academy went into operation, and, according to the old custom, awarded the prizes founded by Clemence Isaure. Since then, this festival, associated with so many poetic recollections, has been annually celebrated. The academy assembles in the council-house of Toulouse, which is called the *capitolium*.

JEW, THE WANDERING, OR ETERNAL; a poetical personage of popular traditions, who owes his existence to a story connected with the well-known scene in the history of Christ's passion. As the Saviour was on the way to the place of execution, overcome with the weight of the cross, he wished to rest on a stone before the house of a Jew, whom the story calls Ahasuerus, who drove him away with curses. Jesus calmly replied—"Thou shalt wander on the earth till I return." The astonished Jew did not come to himself till the crowd had passed, and the streets were empty. Driven by fear and remorse, he has since wandered, according to the command of the Lord, from place to place, and has never yet been able to find a grave. This punishment of unbelief and hardness of heart—a condemnation to wander for ever on the earth, and to be the contemporary of all centuries—has afforded materials for the poets and novelists. Shelly, Monk, Lewis, Dr Croly, and Mrs Norton in England, and Schubart and Schlegel in Germany, have turned this legend to ac-

count. Goethe (in the third volume of his own *Life*) has sketched Ahasuerus, with great spirit and humour, as a philosophic cobbler at Jerusalem, who opposes the Saviour with a cold, worldly logic, which will not look above the things of earth, and is therefore condemned to remain in this world (which is all to him) until a desire for higher things should awaken in him.
